One of the chief aims of the contest is the stimulation of interest and participation by business men through the chamber of commerce. More than 3,000 leading business men are identified with the committees set up to sponsor these contests through the chambers of commerce. The value of participation by these business men is conceded to be much greater than any competitive value there may be in the relative position of municipalities in the contest.

The grading committee will meet on April 10, and announcement will be made of the winning cities and counties about May 1.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Charles R. Blake, M.D., Box 1297, Richmond, Calif., Commissioner of Health

Thomas Burk, M.D., Columbia, La., Director, Caldwell Parish Health Unit

Austin McM. Clarke, M.D., D.P.H., Lakeville, N. B., Canada, District Medical Health Officer

H. B. Cottrell, M.D., C.P.H., Indianola, Miss., Public Health Officer

Albert J. Eller, M.D., Wilkesboro, N. C., Wilkes County Health Officer

Charles W. Folsom, M.D., Health Dept., Lafayette, Ga., Walker and Catoosa County Health Commissioner

William B. Furman, M.D., Pickens, S. C., Pickens County Health Officer

Jesse K. Grace, M.D., Danville, Ark., Yell County Health Director

Robert H. Hutcheson, M.D., C.P.H., State Dept. of Health, Nashville, Tenn., Acting Director, Local Health Service

Alstrup N. Johnson, M.D., Court House, Medford, Ore., Jackson County Health Officer

James E. Johnson, M.D., South 2nd & Rogers Ave., Fort Smith, Ark., Medical Director, Sebastian County Health Unit

Charles R. Keyser, M.D., Van Wert, O., County Health Commissioner

John M. Kimmey, M.D., M.P.H., Clanton, Ala., Chilton County Health Officer

James L. King, Clinton, S. C., Health Officer

Edwin A. Locke, M.D., 226 Main St., Williamstown, Mass., Director, Dept. of Health and Athletics, Williams College

Charles H. Love, M.D., Aberdeen, Miss., Director, Monroe County Health Dept.

Francis E. Mahla, M.D., 65 Front St., Columbus, O., Assistant State Director of Health

William R. May, M.D., Brookhaven, Miss., Director, Lincoln County Health Dept.

J. Arthur Melanson, M.B., D.P.H., City Hall, Moncton, N. B., Canada, District Medical Health Officer

Walter A. Minsch, M.D., Athens, Ala., County Health Officer

Manuel Morales y Fraile, Velazquez 26, Madrid, Spain, Medico del Servicio Antipaludico de la Direccion General de Sanidad

Morris Morgenstern, M.D., 552 Crown St., Brooklyn, N. Y., Medical Inspector, New York City Dept. of Health

L. M. Piatt, M.D., Ottawa, O., Putnam County Health Commissioner

Joseph K. Smith, M.D., 1950 Quincy Dr., Bakersfield, Calif., Kern County Health Officer

S. C. Tatum, M.D., Center, Ala., Cherokee County Health Officer

Robert W. Todd, M.D., Dr.P.H., 223 New Court Bldg., New Orleans, La., Director, Bureau of Parish Health Administration

Louis V. Waldron, M.D., 27 Radford St., Yonkers, N. Y., Commissioner of Health

G. Douglas Williams, M.D., City Hall, Monroe, La., Director, Ouachita Parish Health Unit

Mark W. Welch, M.D., 207 Washington Ave., Endicott, N. Y., Health Officer

Maurice S. Whiteside, M.D., Cullman, Ala., County Health Officer

Clara C. Wilder, R.N., Dept. of Health, Painesville, O., City Health Commissioner

Laboratory Section

Irma M. Azcona, Rapides Parish Health Unit, Alexandria, La., Medical Technologist and Assistant Director, Public Health Laboratory

H. A. Burnett, Jr., 920 Henry St., Detroit, Mich., Bacteriologist, Difco Laboratories, Inc.

Wesley C. Cox, M.D., 1431 Holly St., N.W., Washington, D. C., Laboratory Officer, Walter Reed General Hospital

Florence L. Evans, Ph.D., 316 L.S.U. Bldg., Charity Hospital, New Orleans, La., Junior Pathologist

Sylvester E. Gould, M.D., Eloise Hospital, Eloise, Mich., Pathologist

James A. Harrison, Ph.D., Biology Dept., Temple University, Philadelphia, Pa., Teaching, Research in Bacteriology

Glenn C. Holm, Iowa State College, Ames, Ia., Teaching Veterinary Hygiene

Gustave A. Matson, Ph.D., University of Montana, Missoula, Mont., Professor of Bacteriology and Public Health

Reginald Miller, 125 Worth St., New York, N. Y., Chemist in Charge, Dept. of Health

Helen Parsons, 402 N. Cleveland Ave., Canton, O., Director of Laboratory, City Health Dept.

Carl H. Waite, 119 Conti St., Mobile, Ala., Director, Mobile Branch of State Laboratories

Edward A. Watson, Animal Diseases Research Institute, Hull, P. Que., Canada, Chief Pathologist

Public Health Engineering Section

Roger E. Breard, P. O. Box 1030, Alexandria, La., Sanitarian, Rapides Parish Health Unit

Marvin F. Carter, Rm. 105 Courthouse, Memphis, Tenn., Technical Assistant to Sanitary Engineer, Dept. of Health

Russell L. Johnson, 70 Hull St., Coldwater, Mich., Sanitary Engineer, Branch County Health Dept.

Industrial Hygiene Section

Ethel W. Langenberg, R.N., 800 Empire Bldg., Milwaukee, Wis., Industrial Nursing Field Worker

Edgar Mayer, M.D., 470 Park Ave., New York, N. Y., Assistant Professor of Clinical Medicine, Cornell University Medical College

Child Hygiene Section

William L. Hughes, Ph.D., Teachers College, Columbia University, New York, N. Y., Associate Professor of Physical Education

Ralph H. Pino, M.D., 1001 David Whitney Bldg., Detroit, Mich., Medical Consultant, Sight Saving and Braille Work, Public Schools

Wallace L. Poole, M.D., M.P.H., Box 265, Jonesboro, Tenn., Director, Johnson City and Washington County Health Departments

Public Health Education Section

Morris Cramer, D.D.S., 2000 Eutaw Place, Baltimore, Md., Supervisor, Division of School Dental Clinics, City Health Dept.

Jacob E. Goldstein, M.D., 31 N. 11 St., New Hyde Park, L. I., N. Y., Health Officer and School Physician

Marjorie B. Illig, 1250 Sixth Ave., New York, N. Y., Lay Field Representative, American Society for Control of Cancer

Edward C. Podvin, M.D., 4751 Park Ave., New York, N. Y., Executive Officer, Bronx County Medical Society

Maurice G. Postley, 2842 Grand Concourse, Bronx, New York, N. Y., Secretary, Dept. of Health

Adolph J. Roth, D.P.H., Pullman, Wash., Assistant Professor of Bacteriology and Hygiene

Mildred C. Rouse, R.N., 1407 Eleanor Ave., Toledo, O., School Nurse, Board of Education

Raymond G. Upton, Nacogdoches, Tex., Teacher, Biology and Public Health, Stephen F. Austin State Teachers College

Public Health Nursing Section

Ruth J. Cramer, R.N., 4755 W. Beloit Rd., Milwaukee, Wis., Public Health Nurse, Health Dept.

Emma Danheim, R.N., 602 Lamar, Houston, Tex., Teacher of Public Health Nursing, Memorial Hospital

Llouella L. Haage, R.N., 129 Magnolia Ave., Jersey City, N. J., Supervisor of Public Health Nurses, Board of Education

Ruth E. Lutz, R.N., Visiting Nurse Association, Oshkosh, Wis.

Lucy E. Massey, School of Applied Sciences, Western Reserve University, Cleveland, O., Assistant Professor of Public Health Nursing

Pauline Tarver, R.N., Ouachita Parish Health Unit, Monroe, La., Public Health Nurse

Epidemiology Section

Charles D. Bowdoin, M.D., C.P.H., State Dept. of Health, Atlanta, Ga., Chief, Division of Epidemiology

William Grossmann, M.D., State Office Bldg., Richmond, Va., Assistant State Epidemiologist

Unaffiliated

Dr. Abdurrahman Besen, Kocaeli sitma mucadele heyeti reisi, Izmir, Turkey, Chief, Anti-Malarial Committee

Joseph E. Paulin, M.D., D.P.H., Tracadia, N. B., Canada, District Medical Health Officer

William F. Roberts, M.D., 2 Douglas Ave., St. John, N. B., Canada, Minister of Public Health

DECEASED FELLOWS AND MEMBERS

E. T. Hanley, M.D., Seattle, Wash., Elected Member 1925, Fellow 1930

Professor Royce R. Long, Stanford University, Calif., Elected Member 1919, Fellow 1923

Ida M. Alexander, M.D., Lansing, Mich., Elected Member 1929

Joseph A. Cooke, M.D., Meriden, Conn., Elected Member 1930

Albert Pfeiffer, M.D., Albany, N. Y., Elected Member 1925

Vergil Ross, M.D., Champaign, Ill., Elected Member 1930

Arthur C. Weinberger, New York, N. Y., Elected Member 1926

J. Blake White, M.D., New York, N. Y., Elected Member 1920

Francis X. Mahoney, M.D., Boston, Mass., Elected Member 1912, Fellow 1922

Archie Cole, Pampa, Tex., Elected Member 1931

W. H. Peters, M.D., Cincinnati, O., Elected Member 1913, Fellow 1927

Edgar Sydenstricker, New York, N. Y., Elected Member 1917, Fellow 1922

NEWS FROM THE FIELD

Dr. Parran Nominated Surgeon General of the U.S.P.H.S.

THOMAS Parran, Jr., M.D., has been nominated by President Roosevelt to succeed Hugh S. Cumming, M.D., as Surgeon General of the U. S. Public Health Service. He has been State Health Commissioner of New York since 1930.

Dr. Parran received his medical degree in 1915 from the Medical School of Georgetown University in Washington, D. C.

Thomas Parran, Jr., M.D.

Following his graduation, Dr. Parran served as resident physician at Sibley Memorial Hospital in Washington and later accepted a temporary appointment in the U. S. Public Health Service in connection with field investigations of rural sanitation in Greenville County, S. C., Obion County, Tenn., and Clay County, Mo. He entered the commissioned corps of the Service in March, 1917, since which time he has had a variety of assignments.

In 1926, he represented the United States at an interchange of public health officers held in Denmark. In 1925 he visited Europe for the purpose of studying methods of control of the venereal diseases. During the latter part of 1926, he was assigned as Assistant Surgeon General in Charge of the Division of Venereal Diseases of the Public Health Service. Early in 1930, Governor Roosevelt of the State of New York requested the loan of Dr. Parran to act as State Health Commissioner for New York. He has served in that capacity since that time.

For 10 years Dr. Parran has been chairman of a coöperative clinical group organized for the purpose of studying methods of treatment and control of syphilis. This group consists of the clinicians in charge of 5 large venereal disease clinics in some of the leading hospitals of the United States. He has been actively identified in an advisory capacity with a number of the volunteer health organizations such as the American Society for the Control of Cancer and the American Social Hygiene Association.

In July, 1935, Dr. Parran was appointed a member of the Scientific Advisory Board of the National Research Council. He was also appointed a member of the Advisory Council of the Henry Phipps Institute of Philadelphia in October, 1935, succeeding Dr. William H. Welch, deceased, of Baltimore. He was Chairman of the American delegation attending the International Congress on Dermatology and Syphilis which was held in Budapest in the fall of 1935.

He is a member of the Albany County Medical Society, the New York State Medical Association, the New York Academy of Medicine, and the American Medical Association. He is the author of a number of papers dealing with public health and scientific subjects.

Dr. Parran if appointed will be the sixth Surgeon General of the U. S. Public Health Service. He will be the first Surgeon General of the Public Health Service who has served as state health officer prior to becoming Surgeon General. Previous to assuming his duties as State Commissioner of Health in New York, his experience in state health work was extensive.

Dr. Parran was Treasurer of the American Public Health Association from 1931 to 1933, and Chairman of the Executive Board from 1933 till the Annual Meeting in Milwaukee in October, 1935, when he became President-Elect. He will assume the office of President at the Sixty-fifth Annual Meeting in New Orleans in October of this year. He has been a member of the Association since 1919, and a Fellow since 1923.

DEATH OF DR. NICOLLE

DR. Charles Jean Henri Nicolle died in Tunis on February 28. Born in Rouen, France, September 21, 1886, he was known and honored throughout the world for his contributions to public health and particularly for his discovery in 1909 of the louse transmission of typhus fever. Then, "for the first time in all the centuries of a one-sided warfare, with man forever in the open and typhus ever in ambush, the victim was in a position to organize a rationally planned and strategically sound defense against his historic enemy." *

* Zinsser, Hans. *Rats, Lice and History*, 1935, p. 295.

At the time of his death Dr. Nicolle was director of the Pasteur Institute branch in Tunis, which city he is said to have made one of the healthiest in Northern Africa. His work on typhus fever began there in 1906 when the city experienced a serious epidemic.

Working first with chimpanzees and later with apes, he demonstrated that the typhus virus existed in the blood of patients and that convalescent serum conferred immediate though temporary immunization. His studies made possible the epidemic control of the disease through sanitary measures designed to destroy the route of infection through the body louse. It has been stated that if such control had not been possible the World War would have been brought to a standstill by one vast typhus epidemic affecting all European fronts.

Dr. Nicolle also made notable contributions to the treatment and prevention of yellow fever, undulant fever, Malta fever, measles, and other diseases. In 1928 he was awarded the Nobel Prize in Medicine.

In addition to his scientific eminence he was known as a graceful and entertaining writer. In awarding him the Carthago Medical Prize in 1922 it was noted that he was equally eligible for that fund's literary prize.

In his passing, the world loses another hero of the Pasteur tradition.

MASSACHUSETTS ASSOCIATION CHANGES NAME

THE Massachusetts Association of Boards of Health held its annual meeting in Boston on January 30, and decided at that time to change the name of the Association to "The Massachusetts Public Health Association." The large meeting, including gatherings of the three sections, was addressed by Prof. C.-E. A. Winslow, of Yale University, on "Opportunities and Possibilities in Public Health."

New Officers of the Association are:

President: Paul R. Withington, M.D., Milton
First Vice-President: Ernest M. Morris, M.D., Fall River
Second Vice-President: Prof. Curtis M. Hilliard, Wellesley
Secretary-Treasurer: G. Donald Buckner, Needham

Other members of the Executive Committee are:

Henry D. Chadwick, M.D., Boston
William O. Hewitt, M.D., Attleboro
Charles F. Wilinsky, M.D., Boston
Harold D. Chope, M.D., M.P.H., Newton
L. Jackson Smith, M.D., Springfield

Representatives of the sections are:

John J. McGrath, of Salem, Board of Health Section
Edwin H. Place, M.D., Boston, Laboratory Section
Raymond S. Patterson, Ph.D., Newton, Child Hygiene and Public Health Nursing Section

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

AT its Annual Meeting on February 22, 1936, the Southern California Public Health Association elected the following officers:

President: Dr. Raymond V. Stone, Los Angeles
President-Elect: K. H. Sutherland, M.D., Santa Ana
First Vice-President: W. L. Halverson, M.D., Pasadena
Second Vice-President: F. D. Sweger, Los Angeles
Secretary-Treasurer: Charles W. Arthur, Pasadena

UNIVERSITY OF CINCINNATI DEPARTMENT REORGANIZED

THE Department of Preventive Medicine at the University of Cincinnati has been organized from the former sub-department of Bacteriology. Thomas J. LeBlanc, Sc.D., C.P.H., and W. E. Brown, M.D., are in charge.

INTERNATIONAL NURSING REVIEW

PUBLICATION of the *International Nursing Review* has been resumed, after the lapse of a year. The management of the *Review* has been entirely reorganized.

It is to appear as a quarterly magazine, and will be published at the headquarters of the International Council of Nurses, 14 Quai Gustave Ador, Geneva—to which address subscriptions (Swiss francs 8 per annum) should be sent.

PERSONALS

HELEN M. HOWELL, R.N., has been appointed to the staff of the West Virginia State Health Department as Director of Nursing Education, a service being developed under provisions of the U. S. Public Health Service. The educational program as planned under the Virginia State Health Department will include institutes, group conferences, individual instruction for the public health nurses already employed, and the establishment of a training center for nurses entering the service.

HULDA A. B. CRON, R.N., Director of the Public Health Nursing Association, Evansville, Ind., member A.P.H.A., is taking a year's leave of absence to study public health at Teachers College, Columbia University, New York.

JOHN L. JONES, M.D., of Cleveland, O., member A.P.H.A., has been appointed Health Officer of Medina County, O., to succeed Dr. Thomas W. Mahoney.

DR. CHESTER A. BENNETT, of Strasburg, O., has succeeded Joseph Blickensderfer, M.D., of New Philadelphia, O., F.A.P.H.A., as Health Officer of Tuscarawas County.

HARRY K. GIDLEY, formerly connected with the Kellogg Foundation of Michigan, has been placed in charge

of the West Virginia WPA rural sanitation program, succeeding Fred T. Foard, M.D., F.A.P.H.A., who was recently transferred by the U. S. Public Health Service from Charleston to San Francisco, where he is Regional Consultant for the Service in a territory embracing 9 states.

LINWOOD FARLEY, M.D., member A.P.H.A., has been appointed Health Officer of Hanover County, Va., with headquarters at Ashland.

DR. WILLIAM B. KEELER, recently appointed Health Commissioner of Boston, Mass., to succeed the late Francis X. Mahoney, M.D., Fellow A.P.H.A., was the guest of honor at a dinner held in Boston in January and attended by 428 persons. Dr. Keeler has been connected with the Health Department staff for some years. Charles F. Wilinsky, M.D., F.A.P.H.A., who acted as host and toastmaster, will continue as Deputy Commissioner of Health.

DR. WILLIAM T. HARPER, of Fayette, Miss., has been appointed Director of the part-time health unit in Jefferson County.

DR. THOMAS W. MAHONEY, of Medina, O., Health Officer of Medina County, has been appointed Health Officer of Lucas County, with headquarters in Toledo, O., succeeding Dr. Milton R. Kukuk.

DR. CHARLES F. THOMPSON has been appointed Health Officer of Noble County, O., to succeed Dr. George M. Mason.

DR. HARRY G. SOUTHARD, of Marysville, O., formerly State Health Director, has been appointed Health Officer of Noble County, to succeed Dr. John D. Boylan, of Milford Center.

DR. J. WILL PAYNE, of Willow Wood, O., has succeeded Dr. Forrest R. Stewart, of Ironton, as Health Officer in Lawrence County, O.

DR. ROBERT E. HARPER, for 10 years Health Officer of Lawrence County, Ala., has resigned to accept a similar position in Colbert County, with headquarters at Tuscumbia.

DR. PAUL M. THOMPSON, formerly of Spartanburg, S. C., has been appointed Health Officer of the recently created health unit in Henry County.

DR. WILL R. WILLIAMS, of Richlands, Va., was appointed recently to the State Board of Health, to succeed the late Dr. Joseph A. McGuire, of Norton.

DR. QUINTUS H. BARNEY has been elected Health Officer of Altavista, Va., and community, succeeding the late Dr. John Arnold Board.

DR. JOHN W. BOWDOIN, of Bloxom, Va., was recently appointed Superintendent of Public Welfare for Accomac County.

DEATHS

EDGAR SYDENSTRICKER, F.A.P.H.A., Director of Scientific Research, Milbank Memorial Fund, New York, N. Y., and formerly Statistician for the U. S. Public Health Service and Consultant to the Health Committee of the League of Nations, died in New York on March 19.

DR. CHARLES HARVEY ARCHIBALD, retired roentgenologist, of Asbury Park, N. J., died February 28, as a result of burns suffered in his X-ray work years ago. He was 71 years old.

DR. JOHN H. MOUNTAIN, member A.P.H.A., Health Officer of Middletown, Conn., and formerly State Senator, died March 7, at the age of 66.

DR. WILLIAM H. PETERS, for more than 15 years Health Commissioner of Cincinnati, Ohio, formerly a F.A.P.H.A., died March 13, at the age of 54.

CONFERENCES AND DATES

Apr. 1–3, Canadian Section of the American Water Works Association, Hotel Royal Connaught, Hamilton, Ont.

Apr. 8, Annual Meeting of the Massachusetts Tuberculosis League, Hotel Kimball, Springfield, Mass.

Apr. 9–10, American Association of Pathologists and Bacteriologists, Boston, Mass.

Apr. 9–11, American Association of Anatomists, Durham, N. C.

Apr. 14, 15, Central Atlantic States Association of Dairy, Food and Drug Officials, Warwick Hotel, Philadelphia, Pa.

Apr. 15–18, American Physical Education Association Convention, Hotel Statler, St. Louis, Mo.

Apr. 22–25, National Tuberculosis Association, New Orleans, La. Meeting Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Apr. 25–May 2, National Boys' and Girls' Week.

Apr. 28–May 2, 43rd Annual Convention of the Association for Childhood Education, Hotel Pennsylvania, New York.

May, 1936, Food Industries Exposition, Oakland, Calif.

May 1–4, 60th Annual Meeting of the American Association on Mental Deficiency, Hotel Jefferson, St. Louis, Mo.

May 3–6, International Society for Crippled Children, St. Louis, Mo.

May 10, Mother's Day.

May 11–15, American Medical Association Convention, Kansas City, Mo.

May 11–15, 40th Annual Convention—National Congress of Parents and Teachers, Hotel Schroeder, Milwaukee, Wis.

June 10, Spring Meeting of the New York State Sewage Works Association, Lido Beach, L. I., N. Y.

June 20–26, Canadian Medical Association, Victoria, B. C.

June 21–26, Biennial Convention of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing, Los Angeles, Calif. Headquarters will be, respectively: A.N.A., and N.L.N.E., Ambassador Hotel; N.O.P.H.N., Biltmore Hotel.

June 22–25, Annual Meeting of the National Association of Master Plumbers, Hotel Statler, Buffalo, N. Y.

June 24–27, Seventh Annual Meeting, Western Branch, A.P.H.A.—meeting simultaneously with Canadian Public Health Association—Vancouver and Victoria, B. C.

June 27–July 2, National Education Association, Portland, Ore.

July 6–10, 29th Annual Meeting of the American Home Economics Association, Olympic Hotel, Seattle, Wash.

July 6–11, The Royal Sanitary Institute, Southport, England.

July 13–17, American Dental Association, San Francisco, Calif.

Oct. 20–23, Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Positions Wanted

HEALTH OFFICERS

Physician, M.D., Rush Medical College, post-graduate work, University of Paris; 5 years' experience as county health officer and 7 years as city health officer; desires administrative position, large city. Available now. A-215

Young man, C.P.H., M.I.T.; 3 years' experience as sanitary inspector in various health units; desires position as health officer. A-216

Young man, A.B. and post-graduate work in public health, University of Mich.; now employed as supervisor of health survey desires position as health officer. A-217

LABORATORY

Technician, young man, graduate Brooklyn College; extensive experience in laboratory medicine, blood chemistry, bacteriology; several publications in serology; former research worker in Grade A medical school; desires position as medical technician or research worker. L-218

Physician, M.D., Rush Medical College; Ph.D. in Bacteriology, University of Chicago; several years' experience as Professor of Bacteriology in various universities and as bacteriologist and medical director of a commercial concern; desires position as bacteriologist, medical director, or research director. Excellent references. L-219

Man, V.M.D., M.D. in Bacteriology and Ph.D. in Immunology and Pathology, Ohio State University; 10 years' experience in laboratory work; desires position as laboratory director in the South or West. L-220

Young man, M.S. in Bacteriology, University of Maryland; considerable experience in various laboratory positions; desires a teaching position or a position in an institution with an opportunity to do research work. L-221

Young woman, graduate of University of Kansas; experience as director of out-patient department laboratory of University Hospital; desires position as laboratory technician. L-222

NURSES

Qualified and experienced tuberculosis and public health nurse, including school work, organizing and supervising clinics, follow up work; desires position. N-223

Public health nurse, experienced both in institutional nursing and county health work; desires a position as public health nursing supervisor. N-224

MISCELLANEOUS

Physician, M.D. Harvard Medical, C.P.H. Harvard-Technology School for Health Officers; experience as a city and county health officer and as director of the Division of Communicable Diseases in a State Department of Health; desires position as school or college physician or work in vital statistics. A-225

Man, D.D.S. and Ph.D. University of Michigan; author of many articles on public health education; considerable experience as lecturer and editor of publications; desires position as Director, Public Health Education. A-226

Positions Available

Persons with medical and post-graduate education who are seeking employment are invited to communicate with the Executive Secretary in regard to several available opportunities.

ANNOUNCEMENT OF EXAMINATION FOR APPOINTMENT AS ASSISTANT SURGEON (MEDICAL ONLY) IN THE REGULAR CORPS OF THE U. S. PUBLIC HEALTH SERVICE

An examination for entrance into the Regular Corps of the U. S. Public Health Service in the grade of Assistant Surgeon (medical only) is hereby announced to be held April 13, 1936. Applicants must not have passed their thirty-second birthday. They must be graduates of a reputable medical college and have completed at least one year of interneship since graduation, or its equivalent.

Compensation: $3,158 per annum with dependents and $2,699 per annum without dependents.

Persons desiring permission to take this examination should make request to the Surgeon-General, U. S. Public Health Service, Washington, D. C., for the necessary blanks and other information.

MASSACHUSETTS CIVIL SERVICE EXAMINATION

TUBERCULOSIS FIELD NURSE

Last date for filing applications, April 11, 1936, at 12:00 Noon.

Salary: Minimum—$1,560; Maximum—$2,040.

Duties: Under supervision, to perform work in tuberculosis control; to work on the Chadwick Clinics; to perform related work as required.

Entrance Requirements: Applicants must be registered nurses under the State Division of Registration of Nurses. Applicants must have at least one year's experience in public health nursing. Applicants must possess a motor vehicle operator's license.

For further information and application blanks communicate with the Division of Civil Service, Rooms 145-152, State House, Boston, Mass.

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

New report shows

BRAN HELPS MAINTAIN IRON SUPPLY

of the human body

A RECENT scientific study has added important new facts to our knowledge of bran. The November, 1935, issue of the *Journal of the American Dietetic Association* reports a comparative study of bran and egg-yolk, a known rich source of iron.

The subjects were healthy young women. The conclusions developed by the experiment were *"that the iron of egg-yolk and of bran can be used with equal efficiency for the maintenance of iron equilibrium in the human adult."*

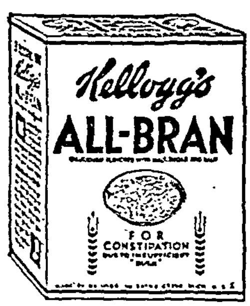
This study continues a series of researches, conducted over a period of five years, in which new contributions to our information on bran have been made. Some of these tests have confirmed the value of bran as a safe laxative food for normal people. Others have demonstrated that it does not lose its effectiveness with continued use.

Further independent tests on men have indicated that the "bulk" in bran is often more effective than that found in fruits and vegetables.

Laboratory studies have shown that Kellogg's ALL-BRAN supplies generous "bulk," which absorbs moisture and gently sponges out the intestinal tract. This delicious cereal corrects constipation due to insufficient "bulk." It is usually more satisfactory for this purpose than the continued use of medicines.

ALL-BRAN may be served as a cereal, with milk or cream, or cooked into muffins, breads, etc. It has a delicious nut-sweet flavor. Sold by all grocers. Made by Kellogg in Battle Creek.

ACCEPTED AMERICAN MEDICAL ASSN.



The natural food

THAT CORRECTS CONSTIPATION

due to insufficient "bulk"

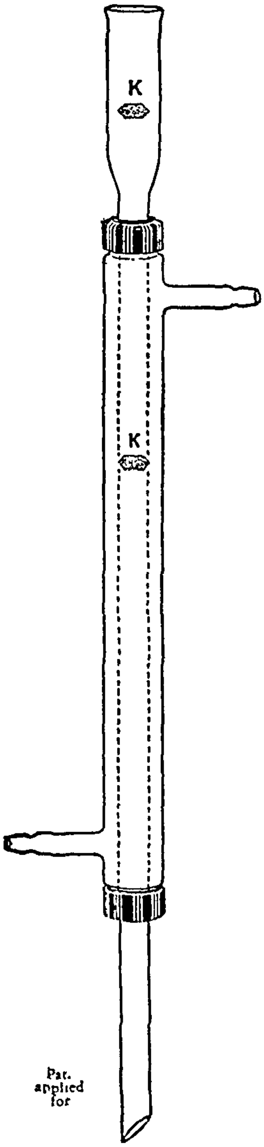
Kimble's Modern Liebig Condenser

BAKELITE NUT AND SCREW THREAD CONNECTIONS

Easy to Assemble and Take Apart



Pat. applied for

OUTSTANDING FEATURES

1. Made of **Kimble Resistant Glass** — with great thermal and mechanical strength.

2. Jacket necks have a standard screw thread finish. The liquid tight connections are achieved by means of a special rubber washer and Bakelite nut. The washer is made of the best grade of heat resistant rubber.

3. The inlet and outlet tubes, which are 1" long, are approximately ½" from shoulders, doing away with dead spaces in the cooling chamber. The ends of these tubes are finished with hose connections.

4. The jackets have outside diameters of ⅞", decreasing considerably the space between inner tube and jacket, giving greater cooling efficiency due to increased rate of flow of cooling medium.

5. The Condenser is easy to assemble and to take apart for cleaning—a particularly good point when cooling water contains iron scale which adheres to the glass and obstructs vision.

6. Thick-walled tubing is used in both condenser tube and jacket. The end of the condenser tube is ground at an angle.

7. The rubber washers are much easier to disengage than either rubber tubing or stoppers, due to smaller area in contact with the condenser tube.

8. Jackets can be easily turned to have inlet and outlet tubes in any desired position.

9. Retempered (strain-free) for maximum strength.

A representative page from the W & T Accounting Department records showing actual maintenance costs on a Visible Vacuum Chlorinator.

THE CHLORINATION DOLLAR

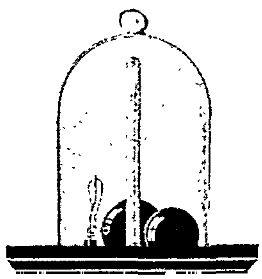
MUST BUY..MAINTENANCE ECONOMY

"HOW MUCH does it cost for upkeep?" is tomorrow's question. With a W&T Visible Vacuum Chlorinator the answer is ready—"Annual maintenance less than ONE PERCENT of the purchase price."

Analysis of repair costs of over 4,000 installations reports this figure. The reason?—Visible Vacuum design,—every working part in plain view under the glass bell jar. No hidden springs or diaphragms to fail, no small parts or orifices to clog, no interruption of Chlorination's vital task.

Ease your mind on chlorination by selecting W&T Visible Vacuum Chlorinators for *dependable, accurate, trouble-free service, at minimum maintenance expense.*

Through years of service tomorrow's taxpayers will applaud your choice of low maintenance equipment.



Technical publications 38, 157 and 158 describe W & T Visible Vacuum Chlorinators. Ask for your copies.

Child Health and the Elementary School*

J. T. PHAIR, M.D., D.P.H., F.A.P.H.A.

Director, Division of Child Hygiene, Ontario Department of Health, Toronto, Ont.

THE average child presents himself for admission to the elementary school under the coercion of the state or provincial authorities at between 5 and 6 years of age. He comes from a home in which consideration for personal health is largely confined to the treatment of manifest evidence of illness, and a casual concern with the major forms of communicable disease. The treatment program is usually a combination of self-medication with patent medicines or home remedies, and orthodox medical care; the preventive program is largely confined to an avoidance of the so-called hardships of quarantine. His health practices are based on racial custom and economic conditions.

The physical condition of this child is subject to the influence of a number of variables, among which are the financial or social position and the health concern of his parents. It is an even break that he is already handicapped with one or more of the half dozen commoner defects. He has probably received the minimum of medical supervision since the period of infancy. His physical activities have been largely confined to doing the things which were either frowned upon or received only a grudging parental approval, on the street, in the backyard, or neighboring vacant lot. He may or he may not know how to play; he has a minimum of interest in work or sustained effort. His mental health has been favorably or adversely influenced by the emotional or intellectual status of his forebears and the attitude of his parents toward life and its problems. Approximately 2,500,000 such children, well- or ill-equipped physically, are thrust through the school doors for the first time, each year in Canada and the United States.

What can we say about him at graduation? In centers in which consideration for the health needs of children have been ignored, we find that the average child upon graduation has acquired certain health habits, some good, some bad. He has an inadequate amount of sound knowledge in support of the good habits, and less that is condemnatory of the bad. He is un-

* Read at a Joint Session of the American Association of School Physicians and the Child Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

duly influenced by dogmas, either those of his race, his parents, or his teacher. To him, newer health knowledge is merely a matter of supplanting old dogmas with new ones.

His dietary habits are largely the result of the ignorance or knowledge of his parents. Unrestrained, he eats what he likes best, in whatever quantities he can get. He sleeps less than he should. He rests not at all. His exercise is acquired as part of his play or work. His habits, in terms of mouth hygiene, are dictated by the interest of the teacher and the enthusiasm of the parents.

Much, if not most of his interest in cleanliness is the result of his environment. (The fact that the majority of the schools in the Province of Ontario make no serious provision for hand washing does little to direct such interest.)

He has vague ideas how communicable diseases are spread, and is more impressed by hardships associated with the measures directed at their control, than the reasons for the existence of such control measures. His physical condition is probably no better than it was at the time of his school entrance.

These comments may seem to some to be non-pertinent or exaggerated; they are, however, based on an interest in the subject of longer standing than I care, at the moment, to admit. Irrespective of their pertinence, and making allowance for the possibility of a more than warranted somber tinging of the picture, the fact remains that nearly one-fifth of our national population is so placed that it can be readily affected by any well considered scheme for health betterment.

The school is an institution operated by the municipality or state and designed best to equip all of those who are considered educable to meet the manifold problems that confront man in his search for social development and spiritual contentment. Granted a whole-hearted acceptance of such a definition of the school's responsibility, then we would be at liberty to proceed with the consideration of how such a program as we have in mind might best be implemented. There are, however, still many who are convinced only of the pedagogical responsibility of the school; while others who grudgingly subscribe to the definition in principle, are rather perfunctory as to its practice. Personally, I am convinced that the major responsibility of the state today is to make adequate provision for an educational program designed to meet not only the intellectual but the social, physical, and emotional needs of this age group.

Appreciative of your interest, I presume to present my conception of such a program as it affects the health of the school age child. The problem has many facets; its solution implies: a state and municipality conscious of its obligations, an appropriate plant, an informed teacher, a concerned parent, an impressionable pupil, supplemented by an appropriate group of auxiliaries. Let us discuss each of these briefly:

State and provincial health authorities have been conscious for some time of the importance of a constructive program adapted to the health needs of children. In the majority of instances, they have exerted all their influence in favor of a well rounded scheme designed best to meet the exigency of the situation as they saw it. In some cases, however, they have unduly emphasized one aspect of the problem and exaggerated the merits of the suggested corrective agency, while others may not have given this matter all the consideration its importance would warrant. Educational leaders, naturally conservative in their viewpoint, have in the past too often either made restrained gestures of friendliness to the advocates of change or viewed

with concern their visionary doctrines. However, there is every evidence that both health and educational authorities are today prepared to give fitting consideration to any well thought out practicable scheme of school health supervision.

What of the school plant? When an official interest in the health of the school age child was first manifested, much was expected in the way of improvement in the school plant as such. That the hopes of the early proponents of such a program have not been realized is due to a diversity of reasons:

First, the dependence of the elected school authorities on the opinion of architects and building contractors and the failure on the part of these to appreciate fully the importance of what is literally implied by maximum hygienic accommodation; second, the lack of well established leadership in this field by the school health staff; and, lastly, by the fact that the direct relationship between indifferent school hygiene and unsatisfactory health is often difficult to demonstrate.

However, the first evidence of an interest in the physical well-being of the school population by the accepted authorities is a desirable type of school building, adequately equipped to safeguard the health of its occupants. The question as to what is implied by this rather casual observation is not easy to answer. Unfortunately, the average school physician is content to accept as fact the presumptions of individuals who are either long since deceased or those who will directly or indirectly profit financially by the acceptance of the opinion expressed.

The first step in the correction of such an undesirable state of affairs is the establishment of accepted standards based on scientific inquiry. Whether each child actually needs a fixed number of cubic feet of air space, and what that number should be; whether cross-lighting is a more serious defect than insufficient lighting; whether the commonly used type of school desk and seat contributes adversely to the present or future ill health of the pupil; and how imperative is the sustained maintenance of a fixed degree of air moisture; are all questions constantly confronting the school medical officer.

While some of the questions of this type may be readily answered, others present apparent difficulty in the way of solution. Until we are in a position to refute specifically the specious arguments and to overcome, by statements scientifically sound and universally accepted, the evident disinterest of those responsible for school construction and maintenance, little can be expected by way of improvement. I urge that consideration be given to the setting up of such standards.

Presuming that the school plant is at least innocuous, we suggest that the teacher is the next significant factor in the establishing of our program. I do not mean next in terms of importance but next in sequence. Actually, I am inclined to resort to superlatives in discussing the place of the teacher in the scheme suggested. Significant might be supplanted by paramount, for without the interest of the teacher, any serious modification of the existing program savors of futility. With such interest raised to enthusiasm, all things are possible.

May I interject here that my comments are based on my experience in that part of Canada with which my official responsibilities compel familiarity. (I am not speaking of tomorrow —because radical changes are proposed.) The average teacher in the elementary school today spent 4 or 5 years in high school—all too often only 4; she came largely from the rural or small urban type of community; her

background was limited, her interest in health matters negligible, her health knowledge equally inadequate. At no time during her preliminary education was a sufficiently serious attempt made to focus attention on the importance of personal or community hygiene. During the period of attendance at the teacher-training school, whatever instruction was given in the subject was largely of an academic character. The instructor was compelled to spend most of the available time bolstering up the student's limited knowledge of the simple principles of physiology, anatomy, bacteriology, and epidemiology. School hygiene is still considered a rather insignificant subdivision of school management, and presumably receives the instructional emphasis that the space devoted to it in the manual would indicate. This is the inadequately seasoned timber which, until today, has been largely available for the building of the essential framework for your school health program.

What of the curriculum? To date, the only provision made is a fixed period of from 20 to 30 minutes, 1 day a week, for all children in the 6th, 7th, and 8th grades, during which the teacher attempts to interpret the contents of the pupil's text. Neither teacher's manual nor reference text has been available for guidance. However, there is every evidence of change and we await with patience the report of those at present engaged in many centers in curriculum building. How can this change be expedited? If the present attitude of the educational authorities in Ontario can be taken as an index of state and provincial interest, then all that is necessary is to avoid a further deferment of hope by a politic presentation of a practicable program; but it is my feeling that in lagging places, the incentive to action must come from those who are professionally concerned with the health of children.

May I be permitted to review the plan which is already in effect in the Province of Ontario? The academic requirements of present and future teachers have been very definitely raised to include the equivalent of the first 2 years of Pass Arts, plus credit courses to be taken in such subjects as—music, art, agriculture, physical education, auxiliary class management, and health teaching. The course in hygiene in the normal training school is supplemented by lectures and demonstrations given by members of the staff of the Provincial Department of Health. The instructors giving such a course are selected on the score of special qualifications for the post. All students are required to pass a thorough medical examination, conducted by carefully selected groups of physicians, the student paying a substantial part of the examination fee. All students showing a positive intracutaneous tuberculin test receive an X-ray examination of the chest, and all those presenting any appreciable deviation from the physical normal are reviewed by a special medical board prior to admission. A teacher's handbook is at present awaiting final approval, a teacher's reference text is in the process of preparation. The question of suitable supplementary readers and pupil's texts is in the hands of the interdepartmental committee on health teaching. The question of adding hygiene to the curriculum of the secondary schools and making it a requirement for those seeking entrance to the teaching profession likewise awaits decision by the same committee. The credit course in health teaching referred to, is a 5 weeks' summer course. After 2 years' experiment, it received this year the stamp of departmental approval. Further, the Provincial Department of Health assists teachers in securing approved health teaching aids and directional material.

There are gaps in the scheme, but they will be filled and we have every hope that in a reasonable time we will have in Ontario a large body of teachers conscious of their responsibility in this field and reasonably well equipped to assume it.

We previously referred to certain auxiliary agencies who had an implied place in any well considered school health program. The physician, the nurse, the dentist, the mental hygienist, and the physical instructor—what rôle are they expected to assume? Consideration of the activities of the school physician and school nurse may be considered jointly in view of the intimacy of their official relationships. They are teamed for a common purpose, namely, the protection of the present and future health of the pupil. They have approached their task through certain well trod avenues; I fear that in some cases, the footsteps of the pioneers have been so assiduously followed that the paths have become ruts.

Control of contagion, detection and correction of physical defects, supervision of school sanitation, and health instruction are hackneyed terms to the introspective administrator in this field; yet consideration must be given to the respective importance of these various components of an acceptable type of service, for example, the control of communicable forms of illness is an essential requisite to an effective child health program. The objective is sound, the method of approach only is in need of review. School nurses continue to devote 30 per cent of their available time to routine classroom inspections, automatically looking for communicable diseases they rarely find, and hours are wasted weekly in the examination of children seeking readmission to the school after unexplained absence, who have already spent half a day or even more in the classroom to which they are hoping to be readmitted. In the event of an epidemic, one finds equal concern being manifested in those who are found, on careful inquiry, to have already had the disease in question, and those who are non-immune. An active instructional program directed at parent, teacher and pupil and dealing with the recognition of the early and prodromal symptoms of the commoner forms of contagious disease, the value of isolation and the merits of the known immunizing agents is worth years of casual inspection.

The school medical officer spends hours in the monotonous task of examining well children, presumably hoping that he may uncover some potential defect at a stage when a medical Demosthenes could not convince the parent or guardian of the significance of his findings. The records are loaded with reported cases of tonsillar abnormality, malnutrition, and postural defect, which are undiscoverable on second examination. The school physician when employed, and I am not perturbed at the moment by the question as to the ethics of his employment, should be primarily concerned with those children who are physically below par, and he should exercise the same interest and ingenuity in securing the correction of the condition present as he does in the care of the sick who seek his help in home or hospital. The school medical officer has a distinct contribution to make, but too much of his time is often devoted to the perfunctory performance of intangible tasks.

What of the dentist? Again I refer to Ontario—the filling of prematurely decayed teeth is his most time-consuming responsibility. Perhaps if dental predestination due to maternal ignorance during the prenatal period is as true as we are led to believe, this is all there is left for him to do. I am not critical, I merely would suggest

that if it is possible of arrangement, the emphasis be shifted from a service to those unable or unwilling to secure it for themselves, to some well considered teaching effort which will be both practical of application and persuasive of appeal. If we must supply dental treatment to the vast bulk of the children of the country, then let us do it overtly as a form of socialized dentistry not thinly coated with the whitewash of prevention.

The mental hygienist—what of him? The present-day classroom is composed of a varying number of individuals, about 40 in number, each with his or her own degree of intelligence, each with emotional responses sometimes difficult to catalogue, physical imperfections not always easy to diagnose, and social reactions often not readily interpreted. This heterogeneous mass is supposed to be guided toward a vague but common objective by a teacher who at best can merely skim from the top of the pot what appears at the surface after stirring.

Our previous teaching program encouraged the studious child to be more studious and forced the restless soul to greater degrees of restlessness. In our early attempts to aid in a better adjustment of the child to his social and academic strait-jacket, we found the emotionally unstable and potentially psychotic among those viewed with favor by the teacher and the constructively minded among the rebellious. Much of our effort was viewed with veiled scepticism by the less well informed teacher, who believed that mental hygiene was concerned solely with the removal from among her pedagogical responsibilities of those with an intelligence quotient below 80. Unorthodox behavior and evidence of emotional instability were, to her, classroom problems which could be handled by disciplinary measures. It has taken much in the way of persuasion to impress on such teachers that it is the psychologist and not the psychometrist who is best equipped to fend off the need for the psychiatrist. Fortunately, the true mental hygienist is a happy blending of all these and truly he has a place in any school health program.

The physical educator had an established status in the school prior to the advent of the school physician, nurse, or psychologist; he was originally a drill instructor, owing his position to the inclusion of a modified form of military drill in the school curriculum in Ontario. Friendly rivalry between neighboring schools as to smartness of appearance and skill in maneuvers kept this movement alive after even its most ardent advocates could no longer defend it on the score of its contribution to the physical fitness of the bulk of the school population. Formal gymnastics introduced by admirers of the German and Scandinavian systems of mass physical activity were avidly seized upon by those groping for some synthetic substitute for the more spontaneous types of exercise. The innate instinct which prompts a child to jump, climb, throw and run could not, however, be long misdirected in unnatural channels, and today we find the leaders in this field not only appreciative of the necessity for providing exercise suited to the needs of each child, but likewise awake to the fact that only that type of physical effort that intrigues and maintains the interest is likely to have any material health significance. Pleasurable periods of relaxation, intriguing forms of group and individual activity are now part of the well ordered school program. Physical activity is an essential factor in optimum health. It is integrated into our work and play from infancy to old age, and directly or indirectly influences man's moral and social habits as well as his physical behavior;

but I might warn the ultra-enthusiast that it is neither the be-all and end-all of child health, nor the panacea for all the ills of mankind.

In conclusion, I would say, first, that much that has been done in the field of school health has been done well and may serve as a useful basis for future effort; much, however, has been indifferently done; and some should never have been attempted. Second, that a well directed interest in the present and future health of this age group is a responsibility jointly shared by the educational and health authorities. Third, that the grade teacher is the individual who has the greatest single contribution to make to any worth while type of school health program, and the special fields of effort with which most of us are concerned, are merely designed to aid the teacher in the better doing of his or her job.

Sunlight and Health

THE number of abnormal conditions primarily and specifically benefitted by sunlight, natural or artificial, is small in comparison with the number for which such claims are made. Sunlight constitutes one of the benefits of an outdoor life; it is one of the elements of climate that make for physical and mental well-being: in extrapulmonary tuberculosis, when judiciously used, it aids and promotes healing; in rickets, certain wave-lengths are specific; but these facts do not justify the extravagant claims made for it as a vitally necessary curative and preventive agency.

Certain diseases and disabilities are partly due to deficient radiation, and doubtless the health of the community may be improved by providing more artificial radiation where sunlight does not reach the small minimum required for health; but sunlight is only one of the many environmental factors that influence health. Climate in its relationship to health is not merely a question of sunlight, but of fresh air, wind, temperature, humidity, altitude above sea level, etc., as well. . . . Sunlight plays a subordinate part in the regulation of physical and chemical processes that make up the life of normal man, who can get along with little or practically none of it, provided his diet be adequate and that he take care of himself in the way of getting plenty of fresh air, sleep and exercise. . . .

Owing to the hypersensitivity of many infants and adults caution should be used in the use of sunlight, both natural and artificial. Over-indulgence, even in the normal, is foolhardy."—Henry Laurens, Professor of Physiology, Medical School, Tulane Univ. *The Scientific Monthly*, *Apr.*, 1936, pp. 312–324.

Effect of E.R.A. on Local Programs*

LAURA A. DRAPER, R.N., F.A.P.H.A.

Director, Minneapolis Community Health Service, Minneapolis, Minn.

THE four agencies in Minneapolis chiefly affected by E.R.A. health and nursing projects were the Health Department, the two public hospitals, and our own association in conjunction with the Department of Public Relief. The two ventures upon which I wish to dwell are, first, that of our City Hospital, and that with which our own organization was associated.

A year ago, when their project started, the Minneapolis General Hospital had on duty approximately 45 general duty nurses, and 135 students. They were faced with the opportunity and the problem of absorbing 75 graduates. They did it, and did it with satisfaction to themselves—to repeat, they added 75 nurses to a general duty staff of 45, and did it successfully almost over night.

The group was composed largely of recent graduates from a number of schools. One problem was introducing them to the routine of the General Hospital as quickly as possible. Motion pictures of certain procedures were helpful. They were of making the empty bed, postoperative bed, showing the morning and afternoon toilet, and the bed bath. The nurses were divided into smaller groups for demonstrations of certain special treatments, such as hypodermic technic, catheterization, etc. A head nurse was assigned to look after the group. The nurses were placed where their experience and their special interest indicated, excluding only the operating room, and for the most part night duty.

This plan worked, and made unquestionable contributions. To the patients it meant more complete care. To the students it meant that they were engaged in only such nursing activities as were educational. To the E.R.A. nurses themselves, it meant experience in a large hospital and an opportunity to demonstrate ability. Nine of them have taken civil service examinations and are now regularly employed at the hospital. This set-up lasted just long enough to show that it could be handled. However, as restrictions became more closely drawn, the 75 nurses dwindled to 8, and when the E.R.A. work terminated last August, it was not a particularly significant project.

The hospital had at that time, however, another project, the cessation of which was a serious handicap. During the past year maid service had been supplied up to as many as 75 women at one time. They had not had formal introduction as had the nurses, but had been assigned to head nurses according to the requisition of the latter. They relieved the nurses of much work which they had of necessity been doing. Julia Miller, R.N., superintendent of nurses, writing about this in July said, "At present it would be impossible to function at all, at our

---

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

present standard of nursing care, without the E.R.A. maid help. Every hour of the nurses' time is thus made available for patients' care."

The E.R.A., I might add, penetrated to practically all the departments of the hospital, out-patient, business office, store room and sewing room, laundry, electro-cardiograph department, diet kitchen, record library, laboratory, and X-ray department. Why all this help could be utilized is indicated, I think, by the fact that in 1934 the patient load had increased over 1930 by 35 per cent, and the expenditure had made only half that increase.

And now, postponing comment, I will turn to the other project, the visiting housekeeper project. This was set up by the Department of Public Relief primarily for families on relief, and fitted into the framework of the Visiting Nurse Association in the belief that the nurses with their intimate contact with families could guide and utilize it to excellent advantage. The Visiting Nurse Association provided office space, transportation, and supplies. In conjunction with the nursing staff of 40, and later of 65, there were for 14 months an average of 5 nutrition workers directing 61 housekeepers.

The purposes of the plan were two; to provide a project for women on relief, and to assist families on relief in budgeting, buying, menu planning, and household management. The plan was to have the housekeeper make effective the teaching of the nutrition worker by demonstration in the home. The nutrition workers were carefully selected home economics graduates. One acted as director of the project, and the others were assigned to individual districts where they were in daily contact with the nurses, and exposed to the nurses' daily work. We were fortunate in having a group which grasped the nursing program and many of its potentialities and problems very quickly. We were allowed free selection also of the women who were sent to us for housekeepers; if because of personality or experience one seemed unsuited to the program, she was not retained. Each housekeeper came first to our central office where she met the director of the project, who discussed her experience and her special aptitudes. She gave the housekeeper a general idea of the program of the association, and stressed her responsibility in representing it. The housekeeper was then assigned to one of the nutrition workers, and thereafter reported to her. The nutrition worker took up any case on which she planned to send the housekeeper in detail with the latter, went with her to introduce her to the home, and if it were a long time case visited occasionally. If one of our nurses was active on the case the nutrition worker did not make supervisory visits unless there was a special problem. Classes were held for the housekeepers twice a month at our central office, the subjects including food essentials, getting the most for your food money, planning well balanced dietaries, diets of children, and stretching the clothing dollar.

The nurses too received a great deal from the nutrition workers. Since many of the families which we were carrying were on relief, it seemed perfectly justifiable for the nutritionists to devote part of their time to promoting their service through the nurses, and they held classes in the substations, at first every 2 weeks, and later once a month. Both the nurses and the field workers in the Department of Public Relief turned to the nutritionists frequently for advice and guidance for individual families.

Just how the service functioned is illustrated briefly in the case of the Beck family. The nurses had known the family for several years. The

mother had died of tuberculosis leaving Mr. Beck and three daughters, aged 17, 15, and 12. They were on relief, and Mr. Beck was doing his best to keep house adequately. Nevertheless, last summer the girls had lost considerable weight, and at the nurse's request the nutritionist visited the home. Finding Mr. Beck fairly intelligent, and very eager for help she explained the principles of good nutrition to him, and left with him some low cost menus and recipes. As the nurse was not active, the nutrition worker made a return visit. Mr. Beck had maintained his interest, and was including green vegetables and 4 quarts of milk in the diet, and carrying out suggestions in various other ways. The nutrition worker invited him to attend a bread making demonstration, with the result that he became an enthusiastic bread maker. As he did not understand the preparation of certain foods, and was anxious to do some canning, a housekeeper was sent to the family for several days. Mr. Beck asked for suggestions for school lunches for the children, which were provided. At the end of the summer the daughters had gained weight, the lowest amount being 7 pounds, the highest, 11.

I have cited this rather simple case to show the interplay between nurse, nutrition worker, and housekeeper, and the assistance which an untrained person can receive, if he desires it.

Last autumn a few of the particularly well adapted housekeepers were selected to give demonstrations of preparation of certain low cost foods at several of the settlement houses. Twenty-one demonstrations were held with an average attendance of 16. The project did not continue long enough to demonstrate to what extent this might be developed advantageously.

The project terminated with our organization last March because at that time the State Emergency Relief Administration felt that it could not be continued with the amount of supervision which we considered essential. We were sure too that it would be maintained under some plan by the Department of Public Relief. This proved to be the case; the project went on in much the same way in that department until August when the housekeepers were discontinued.

The question is, I think, what it accomplished, and what remained as residue after it terminated. What it meant to families is evident. They gained much or little, according to their intelligence and interest. When it was over the Community Health Service had on its staff one nutrition worker, for the Community Fund had agreed that nutrition teaching was fundamental to public health work. The project left us too with a staff of nurses conscious of nutrition and appreciative that it is a fundamental part of health teaching. They are turning to our nutrition consultant for assistance as they probably would not have done had they not had the more intensive experience.

The Relief Department still retains 4 nutrition workers on the S.E.R.A. administrative pay roll. They are acting as consultants to the field staff, having classes and conferences much as our own nutrition worker is doing.

E.R.A. is ended, the W.P.A. and possible other governmental enterprises are before us. Our experience, as I have indicated, was a happy one. E.R.A. workers were never substituted for staff personnel; they were an addition to it. According to our ideas of a few years ago, hasty development of so much service as indicated to the General Hospital and Community Health Service, would have seemed impractical; yet the plans worked, they contributed to patients and to the agencies, and they were worthy of the workers.

Comparative Value of State Districts and County Districts as the Basis of Local Health Organization*

EDWARD S. GODFREY, Jr., M.D., F.A.P.H.A.
Assistant Commissioner, New York State Department of Health, Albany, N. Y.

A SOUND public health program must operate economically as well as effectively. A small unit of population as the basis of organization means either an inadequate service or a high per capita cost. It matters little in the long run whether the funds be derived from local, state, or national sources. Even the gifts of philanthropists must be expended with an eye to the time when those gifts will cease and the organization must be supported from taxes. A splurge of spending means a later readjustment which may be not only painful to the employed personnel but disastrous to the community.

During the past 20 years the county as the unit of local health administration has been so vociferously acclaimed that other methods have not received the consideration to which they may be entitled. There can be no quarrel with the contention that whole-time service is a necessity both in directing and operating effectively local, as well as state and national, health organizations; nor is there objection to be found to the county as the unit of local organization, provided the county contains a sufficient population, sufficient wealth, and sufficient intelligence to support and operate a health department commensurate with the local needs.

That these qualifications are not universally satisfied is easily demonstrated by the census figures of 1930, which show that among the 3,072 counties of the United States, 10 had less than 1,000 population, 250 less than 5,000, nearly a quarter less than 10,000, 40 per cent less than 15,000, over 55 per cent less than 20,000. Over 90 per cent of the counties in the United States were organized before the telephone, the automobile, and good roads made their contributions to communication.

Within what limits of population a health unit can operate effectively and economically has not been determined with any precision. It is not a fixed figure for all present services for all parts of the country or for all time. Our concept of the content of the public health program will change with time quite as surely as it changes with place today. However, there is certainly a lower population limit, and at least one-half of the counties in the United States are below it.

There is probably an upper limit also. The large cities of New York and Baltimore have felt the need of decentralizing and are working toward the establishment of district organizations,

* Read before the Florida Public Health Association at Orlando, Fla., December 2, 1935.

without, however, surrendering the authority of the central office, exacting payments from the districts as such, or supplying personnel and services in accordance with the taxes derived from the areas served.

The vast propaganda for county health departments has two serious evils which must be substracted from its unquestioned benefits in reaching a balance. In the first place, it has emphasized a *name* which covers a variety of services ranging from very little to something approaching adequacy. A whole-time health officer is the single qualification required for admission to the glorified list of "organized" counties. A budget of $4,000 which pays the salary, traveling, and office expenses of a whole-time health officer places a county among the anointed. This is a distortion of values, gives on the one hand a feeling of security and superiority unwarranted by the facts, and on the other arouses alarm over the state of the nation, four-fifths of whose rural territory is not protected by a locally employed whole-time health officer. At least every one in health work has heard of Cattaraugus County, N. Y., and Rutherford County, Tenn., and when the term county health department is used some such organization is visualized. There is as much difference in the existing county health departments as there is in the automobiles seen on the highways.

That there is little to be hoped for in providing the accessory personnel and expenses necessary to the performance of a good journeyman job of health work in small rural counties is attested by the history of these organizations. "Progress," in certain states, consists almost entirely in the establishment of more of the same kind of inefficient or semi-efficient "units." Mountin[1] states that "the budgets of rural health departments tend to remain on a constant low level." Certain state health officers have sought to overcome the difficulty of small county organizations by the consolidation of two or more adjacent counties into districts of suitable size, relying upon their persuasive powers and a subsidy to obtain the consent and coöperation of local authorities in such an arrangement. That these consolidations are difficult to accomplish is indicated by the fact that only 21 of them, comprising 57 counties, were existent in 1934; that they are instable is indicated by the number that have been discontinued or re-grouped.

It is questionable whether anything less than reforming our counties on the basis of modern facilities of communication and modern needs of public service can make the county universally satisfactory as the unit of local health administration. Until this reformation is brought about, such counties must be left in outer darkness, find a suitable and willing mate in the neighborhood, or another method must be developed which will deliver the health service to which every community is entitled.

The second evil to be charged against the propaganda for county "units" is that its very effectiveness has succeeded almost in monopolizing the thinking of public health administrators, of those responsible for the health activities of the philanthropic foundations, of the rank and file of official and voluntary health organizations. The alternative method of state health districts has not received the consideration it deserves. It has never been thoroughly explored in theory and until recent years has not been carried in practice beyond its primitive beginnings. That it possesses potential advantages which in certain respects outweigh those of the county health department I hope to demonstrate in this paper.

1. Under a broad permissive law such as that in New York State, the com-

missioner of health may create any number of sanitary districts, being limited solely by the number of district health officers provided in the legislative appropriation. Either within such a limitation or one specified within the legislative act itself, districts may be established which provide an area and population suitable to the requirements of efficient administration. The effort ordinarily necessary to "sell" a county health department to a reluctant county board can be applied with equal or greater advantage to the state appropriating authorities.

2. Such a system provides a sound foundation for "a career service in which standards of ability and professional qualifications constitute the exclusive basis of preferment."[2] Without such a foundation a career service in public health must ever be hazardous, dependent, beyond the current term of office, on the vagaries of local politics, local prejudice, local whims. It is common experience that a local appointing officer or board will appoint a non-resident only with great reluctance, whereas they will accept a non-resident appointed by an outside authority without resentment. His subsequent success or failure is a matter of his personal and professional qualifications.

Within an established corps, promotion can be systematized, ability rewarded, and mediocrity absorbed in subordinate positions. Individuals exhibiting a flair for some specialized branch can be aided and encouraged to perfect their training in that specialty with assurance that a suitable outlet for their abilities will be available. Such a career service can best be protected by an established state civil service including other departments of the state government.

3. The selection of the district health officer, the determination of the number and quality of accessory personnel under him, and the operating expenses can be based on the needs of the district and not on its ability to pay. To quote again from Dr. Bishop's presidential address[2]: "frequent observations show that the regions with the smallest resources are confronted with the largest need for health service." This is true also of other government services, notably education, and the situation is not met adequately with grants-in-aid that require matching by local funds. No city apportions its services to its several wards according to the amount of taxes collected from them respectively. Nor does it demand that in order to receive a service a section shall pay an additional price. Why should the state make this demand?

As a matter of fact, need and ability to pay probably show an inverse correlation of a very high order, and the same justifications that exist for grants-in-aid hold for supplying the services without conditions. That epidemics know no local political boundaries has become a platitude. That the uncorrected defects of childhood and the neglect of such chronic infectious diseases as tuberculosis and syphilis may impose their later burden of expensive care on a community far away from their origins is not so well appreciated. Americans are migratory—23.4 per cent of the people enumerated at the census of 1930 were born outside the state in which they were residing. We have no figures on the unquestionably greater migration within state boundaries.

4. The poorer districts need in all probability not only more personnel per capita, but a better trained personnel and a directing head of the highest order. The reverse obtains under ordinary circumstances. The small "organized" county with limited resources is the one with the untrained or inexperienced health officer with no assistants, who, if he be young and ambitious, looks upon it as a stepping

stone to something better. He receives such direction, supervision, and advice as a director from the central office can spare him in common with perhaps 20 to 70 others. As the health officer of a small district he probably receives less attention than his more "important" brethren. Would it not be better for him, for the district, and for the service, if his district were part of a larger one, if he were an assistant on a larger staff, if he were learning under direct supervision, if he were acquiring training in handling subordinates, in using clerks and stenographers? Would not the sanitary inspector work better under the supervision of a sanitary engineer, the nurses under a supervising nurse? The lives of some of these supervised people might not be any happier, but I am sure that, whatever their monthly reports might say, their work would be more purposeful and more effective. Accompanied by appropriate reading, this in my opinion far excels as a training program anything to be expected of a "short course" in a public health school or a "training center." It can and should be designed not only for health officers but for sanitary engineers, inspectors, and nurses.

5. As a state district is not fixed by a unit designed for general governmental purposes, its boundaries may be changed from time to time with a minimum of formality. County lines are usually observed to avoid more than one district officer's dealing with the same county board, but a county may be transferred from one district to another or even made a separate district with little disturbance. This is a decided advantage over the county unit system since it provides a coverage for the entire state, which even though it may be thin is not so thin as that to be expected from a central office. The size of the districts may be adapted to the capacity of the officer in charge, and districts may be subdivided and readjusted as personnel is acquired and trained.

6. The personnel being appointed and paid by the state, the authority is direct, there is greater identity of purpose and there can be a higher degree of uniformity where that is desirable. At the same time, it does not interfere with careful experimentation in the field of administration. This centralized authority also permits prompt concentration of personnel at points of particular danger as in epidemics or disaster.

7. It eliminates local politics, especially if more than one county be included, from the selection of personnel and headquarters, the making of purchases, and prevents the other devious devices which tend to reduce efficiency.

8. Highly specialized services provided by the state, such as for orthopedics, tuberculosis, syphilis, maternity and infancy hygiene, etc., can be readily integrated. These may cover more than one district. In the case of a large district or a specific problem, a specialist may be assigned.

9. It is more economical than dissociated units. Supplies can be bought more cheaply through a central bureau and the quality of the materials insured. Personnel of higher quality can be employed for the same or even lower salaries than are paid by local governments. The increased security against dismissal or demotion for arbitrary or extraneous reasons, the greater opportunities for promotion, the larger opportunities for self-improvement are attractions that appeal to men and women of the type needed in public health work. The problem of recruitment is thereby made less difficult.

It has been stated or implied [3] that local financial and official participation are essential to the acceptance and maintenance of good local health work. Lumsden cites the discontinuance of the

district system in Vermont after 4 years' experience with it "as an illuminating example of a state doing more than its proportionate part in local health service." I will not comment on the social philosophy which apparently underlies that statement, but merely point out the lack of evidence which would warrant the conclusion.

Ten state districts were established in Vermont in 1919, each with a district health officer. The total appropriation for district work was $40,000 per annum or an average of $4,000 per district. Presumably therefore there was no accessory staff and no district office. We are not informed as to the personal and professional qualifications of the district officers, whether they embarked on a program of wider usefulness than the part-time local health officers whom they superseded or fell into the rut of routine. In retrospect at least, one may question the wisdom of the precipitate creation of so many districts in so small a state. Fewer districts, each better implemented and giving a more varied and intimate service, might have survived.

Despite this casualty there are 6 states which have district systems without local participation.[4] Four have been in existence for over 20 years, 2 others for over 8 years. It is readily admitted that they have not been developed as they might have been with the possible exception of Delaware, which operates 3 state districts in its 3 counties. In part, this may be due to the difficulty of obtaining the necessary legislative appropriations. But in greater measure it may be due to a continuance of the original policy of supervision of local personnel, and failure to recognize and test the potentialities of the state district as an operating agency. As to its capacity for gaining local interest and support, the district system in New York State survived a concerted attack in its incipiency due to the support it received from people throughout the state. It has never been questioned since.

The results from increasing our district staffs in New York State during the past 5 years have been such as to encourage a continuance and expansion of this policy. It is not intended that this shall discourage the establishment of more whole-time health departments in counties desiring a more complete service than can be provided at present by the state. It means rather a change of emphasis. Our experience with the additional personnel made possible by a grant from the Rockefeller Foundation and last year's federal aid, has shown that it is possible to integrate the state and local services in rural districts and to supplement the local services in cities in a highly satisfactory manner. Relieving the district officer of much of the routine and emergency duties is making possible purposeful efforts in the prevention of syphilis, tuberculosis, and infant and maternal mortality. As personnel and experience are acquired, other imperfectly developed fields can be cultivated with greater promise of success than with locally operated departments.

Public health work in this country is at a critical point. The passage of the Social Security Act has authorized the Congress to appropriate considerable sums of money for grants-in-aid to our states and territories. Upon the wisdom and the integrity with which these funds are spent will depend not merely their continuance but perhaps the continuance of existing appropriations from state and local governments. I am not thinking of the possible "drying up" of local appropriations through a shift of the burden to the national government. I am thinking of an actual revulsion against health work if the money be diverted to serve personal or partisan purposes; if it be spent foolishly or extravagantly by the

well intentioned. The former can happen despite the qualifications that may be required for professional personnel; the latter can happen through grants that are not proportioned to the need or that exceed the capacity of the state or local health organization to administer.

There is some reason for concern in the emphasis placed on grants to local health departments in the tentative proposal of the Surgeon General for the allocation of funds under Section VI of the Act. Restricting the amount available for the central state health department to a fixed fraction of the total allotment may result in the maintenance of those departments at a level incompatible with efficiency. They will thus be unable to furnish either the amount or the quality of service to the local departments that the latter require. The quality of the work of the state health department largely determines that of the local departments. Rarely do they rise above it. When they do, it may well be a cause for shame that the state standard is not higher, rather than a cause for pride in the achievement of a local unit. The state must be prepared to furnish not only a high order of administrative guidance but a high quality and recognized leadership for the essential specialized services.

The proposed regulations of the Social Security Act provide that aid may be given to full-time district organizations, and state created and operated districts are therefore equally eligible with those established locally.

I submit that local interest and support can be developed for a system of state districts each under a whole-time health officer as well as for a system of locally operated departments. Public health service always expresses itself locally, whether in services to an individual, a family, a group, or to a community. Where that service comes from and what agency furnishes the funds are of less moment than the quality of the service and the spirit in which it is given. The state district system provides a service that can be superimposed on any existing system without undue delay or disruption, a universal coverage, not a mottled one, a service adapted to local needs rather than local wealth.

Integrating Mental Hygiene*

From the Point of View of the Public Health Officer and School Physician

FREDERICK L. PATRY, M.D.

Psychiatrist, State Education Department, University of the State of New York, Albany, N. Y.

THE keynote of enlightened attitude toward mental hygiene in the field of public health was sounded several years ago by the organizer of this Special Session on Mental Hygiene. In his wisdom and critical prevision Dr. Haven Emerson stated what has now become a well known accepted dictum:

> We have arrived at a point in the organization of our national effort for health where advances in the fields already preëmpted and liberally supported by public opinion and resources must wait for their entire success upon a fair beginning and progress in the most delicate and difficult and yet the most promising undertaking of all—the prevention of nervous disorders and mental defects.

The facts of the need and importance of mental health problems have been abundantly driven home statistically, through personal and group experience, and otherwise. We shall therefore proceed directly to the nub of our assignment, bringing to the front facts which make for collaboration between the public health officer and the school physician for the purpose of protective and preventive mental guidance of school age children. Our chief concern will be with definite practices and organization under official agencies of services directed toward the prevention and control of mental disease, and their precursors, personality and behavior disorders or maladjustments.

Perhaps the most fruitful approach to our collaboration is to begin with concrete examples of points of view with respect to mental hygiene, expressed by health officers and school physicians. If one is to be helpful to another, he must first gain an intellectual, but particularly an emotional, understanding of the facts under consideration; he must be able to put himself into the shoes of the other person in order to sense his mind-set and feel with him in his problems. Let us therefore swing into center-stage position the reactions of a number of public health officers and school physicians to our topic, keeping in mind that over 60 per cent of school physicians also function as public health officers in New York State. We shall first record the physicians' comments, follow them with an attempt at interpretation and evaluation, summarize these facts, and finally present a few concrete recommendations designed to enhance integration of mental hygiene opportunities and obligations. The substance of the remarks of certain health officers and school physicians relative to our topic follows:

1. " The average public health officer

* Read at a Special Session on Mental Hygiene of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

and school physician looks at mental hygiene as something beyond him. It really is not, but it seems so because he steers shy of it. Psychiatric language and technic is often so far removed from the practitioner's understanding and utilization that he does not take a serious interest in it. If he would only get into the habit of consciously applying mental hygiene principles and practices, he would soon realize his capacity and its value. It is something every physician can apply in his everyday practice. For example, during the physical examination of the school child, the physician has an unrivalled opportunity to inject mental hygiene attitudes and habits relative to the physical examination findings and the child's reaction to them.

"We must get away from the old idea that the doctor is only to detect physical defects. He must learn to prepare the child for the health education values of the examination by talking with and to the child; not merely examining him manually or with impersonal diagnostic instruments. His main job is to help prepare the child for healthier, richer, and happier living, chiefly through habit training in the maintenance of health and the prevention of illness.

"The proper emotional acceptance of the physical examination facts is essential. But the physician must not neglect tactful inquiry into the child's ways of living. His main contribution is assisting in the education of the child in the art of living—healthfully, wisely, happily and to the optimum of his potentialities."

The time factor was raised to which this former public health officer, school physician and school medical inspector replied: "The doctor has plenty of time. It is a part of his work, but he does not know it."

Asked how he would "put across" a better mental hygiene attitude and practice to school physicians and health officers, he replied: "The method will have to be individualized and explained in different ways to meet personality types and individual needs. Two-way conferences are perhaps best. Herein the physician has an opportunity to raise problems of interest and concern to him. The discussion conference under the chairmanship of an experienced leader multiplies the educational values of topics discussed through 'contagion.' Others are impelled to pool their experiences to clarify conceptions and that to the benefit of all concerned. The physician may be exposed to facts he already knows, but he gets to see them in a new and more significant light which in turn leads to more effective application of them."

2. "Most school physicians do not know what the words 'mental hygiene' mean. Their general attitude is unfavorable toward mental hygiene. An occasional doctor is all for mental hygiene, especially the full-time school physician. The part-time practitioner has not time to think of mental hygiene; he is too busy with obstetrics and other concerns of his private practice."

3. "My first concern in examining a child is to note whether he appears to be well adjusted, well poised, happy, or whether he is fidgety, tense, or nervous. Evidences of the degree of personality integration can be observed before one can accurately note the child's color, nutritional status, and the details of the various organ-system examinations. Too often, the first and often the only concern of the school physician with the maladjusted pupil is to recommend him to be dropped or exempted from school. He does not seem to be interested in the pupil's further plans and welfare."

With respect to psychiatric part-time service to schools and colleges this school physician stated: "The

inability of the psychiatrist to give sufficient time to the treatment of maladjusted pupils makes his services often unsatisfactory and less convincing. Full-time psychiatrists on the teaching faculties of schools and colleges would help fill a patent need."

Asked as to the need of special training of school physicians in mental hygiene for better serving this part of their work, the informant answered: "The main thing is to use good horse sense."

4. "A few outstanding school physicians see the importance of mental hygiene in handling the child. It colors their outlook and understanding of the child's adjustment to life. They see the whole child.

"Many older physicians have a keen eye for mental hygiene values; others just ignore it and the understanding of problems of pupil adjustment. The recent graduates seem to be doing a better job, perhaps due to better medical school training in this branch of medicine. They see the whole child and have his total interests and welfare at heart.

"The school physician could get much help from teachers in gaining an understanding and handling of pupil maladjustments. The full-time physician usually coöperates well with the teachers. Teachers are usually better prepared by training and experience than the physician in understanding and handling behavior and personality difficulties of pupils. The teacher has the advantage of being in intimate contact with the child some 5 to 6 hours each day. However, the teacher needs the advice of the physician, especially in evaluating his physical status. The school physician could and should be trained to interpret most cases of pupil behavior difficulties and emotional maladjustments, and to treat these quite effectively. The more serious cases should be referred to a psychiatrist attached to the school staff, child guidance clinic, hospital dispensary or the psychiatrist in private practice."

Asked how a school psychiatrist could utilize his time to best advantage to the child with respect to the early recognition and correction of emotional, personality, and social maladjustments, this school physician replied: "Working with the teacher. It is she who is in closer contact and for a longer time with the child, and therefore could do a better preventive mental health job.

"The school physician can play an important rôle in corrective and in positive mental hygiene. The teacher, upon discovering a maladjusted child, usually refers him to the school principal or superintendent who in turn usually seeks the advice of the school physician and school nurse. If the problem seems to need more specialized analysis, psychiatric service is sought.

"Not infrequently, the teacher herself is maladjusted, and is not in a position to understand and handle pupil maladjustments. Thus psychiatric and mental hygiene service should also be available to help teachers handicapped by personality problems.

"The mental health examination should be an integral part of the general physical examination. This is not being done to any great extent at present. The concern of the school physician should extend beyond checking off the mere presence or absence of 'mental abnormality' on the physical examination form.

"The mental health service given by the school physician could be materially improved by realizing the need for special education and clinical experience in this specialty beyond that which he obtained at medical college. Summer and extension courses such as those given at Columbia University to school physicians could be turned to good advantage. But of chief impor-

tance in gaining a working knowledge and practice of school psychiatry is the actual work in a child guidance clinic or psychiatric dispensary, or assistant to a psychiatrist dealing with school age problems. Zone discussion and panel conferences with health officers and school physicians have been of practical help, but there is needed a greater readiness on the part of the physician to seek the services of the psychiatrist in sharing with him behavior and personality difficulties, especially at an early period before serious maladjustments such as delinquency and crime develop.

"Frequently health officers and school physicians are not aware of the local psychiatric facilities available, or they fail to utilize them to the full for various types of mentally and socially maladjusted children. The school principal and superintendent are often better aware of the need of child guidance clinic service than the physician. More education and experience in child development, child psychology, and child psychiatry in pre-graduation days would be of decided advantage to the physician whether he entered general practice or any of its specialties. Relatively few school physicians and public health officers read mental hygiene periodicals or books specializing in this branch of medicine. There is need of jarring many physicians out of the rut of *laissez-faire* methods of regarding and treating the maladjusted child."

5. "The school physician is so busy with looking for physical defects that he skips the mental hygiene opportunities of his work, unless the teacher calls his attention to the pupils' abnormal mental status. The doctor's recognition as to what is mentally abnormal is not very keen. He is schooled in the study of medicine chiefly as a study of disease, rather than prevention of illness and the maintenance of health. Thus the school physician by virtue of only general medical training is handicapped in doing a reasonably good mental hygiene job. On the other hand, most school physicians and health officers would be sympathetic toward mental hygiene if at any time in their career they had been 'sold' to it. As yet, it is beyond their experience. The older physician's psychiatric training consisted in the observation of mentally diseased patients committed to mental hospitals. He has had no instruction in preventive psychiatry or mental hygiene.

"The medical curriculum should be made over. Much of the time spent on histology, for example, should be given over to the study and practice of preventive medicine, particularly the early recognition of conditions and hazards that make for eventual mental breakdown; the prevention of goiter and other preventable and controllable disorders.

"The health officer and school physician could be made psychiatrically intelligent by devising methods which are simple, quick, and concrete for the assimilation of mental health concepts and technics. A 'ten point' formulation of this nature might arrest sufficient attention to spur on non-psychiatrically educated physicians to apply mental hygiene.

"At present, mental abnormalities are brought to the school physician's attention by the teacher, and occasionally the parent. He is willing to coöperate with the teacher, but he does not take the initiative and so this important relationship is often lost. The school physician should talk over each pupil with the teacher before he examines him.

"Mental health should be the first item on the school physician's examination blank. 'Nutrition' might well be displaced to 18th place because

you cannot adequately evaluate it until the pupil is stripped.

"If it were stated in the school physician's contract that the time he must give to the examination of each child per year should occupy a minimum of 30 minutes, the mental health aspects would find less chance of being lost sight of on account of the time factor. Of course, reasonable financial recompense for the physician's time is essential if the pupils' optimal welfare is to be realized."

6. "Some school physicians are so mind-set about their job that they think in terms of so many physical examinations and see how quickly they can get them over.

"Certain physicians have a natural knack of understanding and handling children. But relatively few physicians (general or school) give attention to the mental hygiene aspects of their work. They do not seem to feel need for it, especially those who need it the most. Those who do use it, welcome it. The dentist has made more progress in mental hygiene than the physician. Probably this is because he deals so much with pain and has to be quite expert in psychological medicine to hold his patients. The bedridden patient on the other hand, cannot escape from the physician. Perhaps also the cosmetic attention to the personality in contrast to health status gives the dentist a psychological advantage over the physician who fails to emphasize the health-beauty aspects of his services."

7. "Since over 50 per cent of medical practice is essentially involved in handling mental and emotional difficulties of patients, how can mental hygiene be regarded as a specialty? The general practitioner and school physician must be the main bulwark in treating extramural types of personality and behavior abnormalities. Besides, personal experience with certain psychiatric help has been disappointing and on occasion has led to an increase of troublesome situations."

8. "I acknowledge the immensity and seriousness of the problem of the mentally maladjusted but I do not feel more time and money are at present justified in supporting this branch of medicine until more prompt, effective, and reliable measures are forthcoming. There seems to be nothing in treating mentally maladjusted persons as specific as diphtheria antitoxin or typhoid vaccine. For the present, therefore, service to the mentally handicapped should be regarded as 'dessert' until the physical welfare of the individual is cared for to the fullest extent."

9. "Recently I was asked to give an address on mental health to a lay organization. As a health officer, the people of this district looked upon me as the source of all health knowledge. Although I laid no claim to being an expert in this branch of health, I gave the address. Somewhat to my chagrin I found out after the meeting that there were in the audience a psychiatrist and a psychiatric social worker. But I do not regret the experience.

"I feel that every health officer should obligate himself to gain a working knowledge of the essential facts of mental hygiene. His job is not only looking after the physical welfare of his community, but also its mental health. And this does not imply merely the commitment of persons so mentally ill as to require hospital treatment. It primarily devolves upon him to *prevent* such conditions as far as is within his power and opportunity. Mental hygiene clinics and observation wards in connection with general hospitals and health centers are essential to the early recognition and treatment of the community's mentally ill and maladjusted."

What shall we say about the foregoing opinions of experienced health officers and school physicians? Their

reactions seem to be a representative sampling of feelings and thoughts entertained on the present-day status of mental hygiene. The attitude of these health workers for the most part is decidedly encouraging. To a large extent they have pointed the way to solving most of the problems which interfere with the optimal integration of mental health from the point of view of the health officer and school physician. If the constructive suggestions formulated by these physicians were capitalized, what an impetus would be given to this important branch of medical service!

By way of summary and formulation of a " ten point " program of mental health basic attitude, knowledge and practice for health officers and school physicians, the following guide-posts are erected:

1. The attitude toward, and concept of, health must be amplified to include the optimal functioning of " the person," the individual as a whole. In the short historical march of preventive medicine, we have outgrown our concept of preventive medicine from that of primary concern with the prevention and reduction of human misery due to disease and death. We are no longer merely concerned with longevity *per se,* but the quality of human performance in terms of health, happiness, efficiency, and social adaptation. If we subscribe to this concept, we will stop thinking in terms of mind and body, realizing that they are inseparable and part and parcel of the same thing. We will strive to obtain the biological, psychological, and environmental needs each individual peculiarly requires to develop his constructive potentialities to the optimum.

2. The health officer and school physician should realize to a greater extent their unrivalled opportunity to build the foundations of the total health of the individual by virtue of their educational service to the unborn child, the parents, and their intimate contact with parent and teacher during the plastic period of infancy and childhood. If the foundation of health structure is faulty at its origin, the whole superstructure is jeopardized. The welfare of the child each year depends on the health of the child during the preceding years. Therefore, the best time for realizing our objectives in healthful living on all levels of integration—biological, psychological, temperamental, and social—is during the period of infancy and childhood. Are health officers and school physicians fully aware of their latent and potential possibilities in this regard?

3. Mental health may be regarded as the expression of the individual's adjustment to life in terms of *emotional* satisfaction in the light of his capacities, needs, demands, and opportunities. These depend upon the quality of the individual's original stuff or constitutional endowment, the environmental situations and life experiences affecting him, and how he adjusted and reacted to them from birth onward. Of prime importance are the quality of behavior, feeling-attitude, and compromise patterns woven into the warp and woof of his growing personality. These are the first line of defense of his ability to meet life demands and vicissitudes. Health is essentially a way of living, a dynamic-genetic functioning of the total person seeking satisfactions of his primordial instinctive-emotional component of his being, the mainspring of activity. Behavior is merely a symptom to be interpreted in the light of the individual's reaching out after satisfactions and needs. Behavior is just as much an integral expression of health as is health expressed in behavior. Since the individual reacts always as a total unit, the physical component of the personality should be functioning at its optimum in order

that he may capitalize his day-by-day adjustment demands and opportunities. The soil or hereditary aspect of mental health is important to recognize from the standpoint of positive eugenics and the fostering of the health of coming generations. But apart from the evaluation of individual constitutional endowment in terms of ability to stand emotional stress and strain and the correlative obligation for protection of the child from undue environmental pressure, the chief concern of the physician is in shaping the environmental stimuli so that reasonable success and satisfaction in living with others will be the lot of every person.

4. The school physician should pay special attention to every child who is experiencing failure in school, who is a misfit in the group, educationally or socially, who is unhappy and protesting thereto with " nerves." It must be recognized that fundamentally no child wants to fail. Failure means only one thing—that someone has blundered; someone has failed to show him off to advantage on his own level of ability to succeed. Every child wants to succeed, win social recognition and approval, and experience a wholesome sense of prestige and power—and he will, if we obligate ourselves to understand thoroughly the child's nature and needs and see to it that these are reasonably satisfied.

5. Just as the physician needs to know certain facts in evaluating the physical health of an individual, for example, temperature, pulse rate, blood pressure, blood and urine analysis, and other data, so in the evaluation of mental health we must seek facts of the individual's intellectual capacity, special abilities and disabilities, interests, aptitudes, and talents, as well as his mental conflicts, anxieties, frustrations, ambitions and their discrepancies with reasons for failure of actualization. The physician must familiarize himself with the meaning and estimation of intelligence tests. A large number of pupils complaining of " nerves " and failure in school are so because of the emotional strain resulting from lack of intellectual ability to succeed in the work expected of them. Conference with the teacher in every case of behavior and personality maladjustments is essential for interpretation and reconstruction of the problem. The facts of internal mental disharmony require time and the capacity to attain the pupil's rapport before he will unfold his thwartings, strengths, and weaknesses, anxieties, fears and ruminations. The environmental facts of home emotional atmospheric pressure due to stress and strain must be sought through visiting teacher or social worker, school nurse, or other sources. The enucleation or modification of emotional conflicts absorbed in this area of the child's life may be the means of restoring mental equilibrium. Usually a multiplicity of causes or variables are operating in unbalancing the blending of assets and liabilities. Likewise, it is important to keep in mind the desideratum of a multiplicity of results.

6. Work through pupil strengths and satisfactions to overcome undesirable attitudes and practices. Wholesome substituting, balancing and protecting interests and activities are frequently sufficient to crowd out morbid preoccupations and undesirable habits. Let us keep in mind that just as necessary as food, shelter, and clothing are for each child's physical welfare, so for his mental and emotional health are necessary varying degrees of affection, feeling of security, and belonging to the group, freedom to unfold and organize his creative capacities, and the opportunity to experience reasonable satisfaction of wish strivings and biological urges in everyday living.

7. Learn the normal latitude or range of psychological developmental facts

of behavior. We all more or less present *normal problems* of social adaptation and personality unfolding at various periods of the life span. These may be primarily related to endocrine or situational changes as well as to new integrations ever evolving in mental life organization with consequent shifts of methods in gaining satisfactions.

8. Seek to appreciate better the individual differences in original equipment, reaction patterns to life experiences, arrests in intellectual and emotional development and the causes hereof. The child's creative abilities, probable educational and vocational goal as well as avocational interests deserve particular attention. Create the optimal conditions for success in unfolding and capitalizing constructive individual differences. Cultivate constructive deviations from the norm in creative interests and abilities since it is only through these that human progress is made. One hundred per cent regimentation of human material spells psychic arteriosclerosis and retrogression.

9. Recognize that the home is the most important mental health educational institution of society. Bend every effort to see that every child has this part of his birthright guaranteed. If the start of life's journey is well prepared, we have little fear of maladjustments later on, although it must be kept in mind that human machinery may go awry at any point along the life span, but perhaps 10 to 50 per cent of mental maladjustments are entirely preventable and therefore a prime obligation of the public health officer and school physician. This aspect of health is essentially as important as the individual's and community's physical welfare. As in the treatment of the tuberculous, there is no cut-and-dried specific method of treating the mentally maladjusted. Similarly their reconstruction through reëducation in the art of living may take a period of months or years. But who would say that because we have no quick-cure specific for the treatment of the tuberculous that we will not concern ourselves with their welfare until sure and quick readily applied remedial measures arise? Likewise the tackling of the problems of persons handicapped by venereal diseases and the challenging problem of cancer merit concerted and intensive preventive therapeutic services, largely through public health education. The problems of the mentally afflicted are in no wise less real or less pressing for solution, but rather more so in view of their far greater incidence. Rational educational enlightenment, oftentimes over a long-term period, is necessary to uproot taboos and defenses handed down from one generation to another from the dark ages, and other sources of ignorance.

10. Although we can never dispense with common sense, who would think of practising surgery or any medical specialty without having his "horse sense" critically trained before presuming to be competent or venturing far in these respective branches? Postgraduate education, clinical experience, reading, and the putting to a test of diagnostic, preventive, and therapeutic aspects of psychological medicine, are essential for adequate service until our medical colleges can be won over to give more time to this part of the physician's education. Even then, there will always be plenty of room for the expert or specialist.

The success of the mental health of the individual and the community depends upon the *combined* efforts of the medical profession, professional educators, the clergy, parents, and every constructive socializing agency of the community. The multiplicity of forces shaping human behavior touch the total child every moment of his 24 hour living. It is therefore obvious that only by *sharing* our common obliga-

tion and opportunity according to our several special qualifications, trainings, and experiences, can we hope to do justice to the total health of those for whom we make ourselves responsible. The spearhead of any health program should be made up of those who are best qualified by education and experience to direct and evaluate it. If the medical profession fail in this, our nation's first obligation to the child, to whom can we look for guidance? The sampling of expressions brought to your consideration in this paper clearly indicate the recognition of need and interest of the health officer and school physician in matters of mental health. We dare not, and will not fail in this most challenging and promising opportunity.

May Day—Child Health Day

AT the request of the State and Provincial Health Authorities of North America, the Children's Bureau of the Department of Labor has undertaken the responsibility for May Day–Child Health Day.

According to an announcement made April 8 by Katharine F. Lenroot of the Children's Bureau, the program for 1936 is to be centered on social security for children with special emphasis placed on health protection.

The assumption by an official agency like the Children's Bureau of this function previously carried by the American Child Health Association in coöperation with the State and Provincial Health Authorities marks a significant milepost in the development of May Day–Child Health Day as a point of departure for health department services.

A Community Program for Prevention of Mental Disease*

ELIZABETH I. ADAMSON, M.D.

Associate in Psychiatry, Columbia University, College of Physicians and Surgeons, New York, N. Y.

THERE is a steady increase in mental disorders, for some of which causative factors are recognized, but no community has inaugurated a specific and continuous plan for their prevention. They, like all diseases, will be decreased not by therapy for the individual, but by mass prevention.

Medicine has contributed to civilization's progress largely through preventive measures learned from treatment; therefore, the prevention of disease is a major function of modern health agencies. Lay organizations, supported by private funds, and public health departments, maintained by taxes, no longer confine their activities to therapy. Many physicians work as hard to keep people well as they do to cure the sick. The medical profession and boards of health do not yet recognize that the prevention of mental and emotional disorders—or mental hygiene—falls within their province. No community has an organized program for the prevention of mental disease.

In the *Journal of the A.M.A.*, March 30, 1935, Dr. Ray Lyman Wilbur discussed the weaknesses of our medical curriculum, and mentioned specifically the departments of psychiatry, public health, and obstetrics as those in which improvement is definitely needed. If the teaching of these subjects has lagged, we know least about them and may be unable to appraise their possibilities. Nevertheless, we are offering for consideration a possible relationship between two of them, psychiatry and public health, and inclusion of one in the other, by a community program for the prevention of mental diseases, with special emphasis on those of psychogenic origin, the causes of which we are more able to influence than those of organic origin.

Except in the mental changes resulting from syphilis, alcoholism, and drug addiction, all of which have a distinct psychological component, we know very little about the control of organic psychosis. The prevention of arteriosclerotic, certain toxic, neoplastic, and senile disorders is not yet solved. But of psychogenic conditions we are not so ignorant.

Perhaps due to faulty psychiatric education, some of our public health leaders hold that the etiological factors of these disorders are unknown, and that with no specific cause and with only empirical treatment, prevention is impossible.

Others more familiar with psychiatric findings, and who recognize a causal relation between emotional reactions and mental disease, claim that because of the magnitude of the task they

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

neither know where nor how to begin, and leave the solution of a fascinating problem to time, resting it in the lap of the gods.

Those physicians who are interested enough to ask advice usually say that psychiatrists and mental hygienists offer only theory, and no tangible or practical plan for decreasing emotional disorders. In contrast, they present the definiteness in the mass prevention of diphtheria, typhoid, smallpox, and other communicable diseases.

Even though psychogenic illnesses are not controlled by an instrument such as the hypodermic needle, they are, in many respects similar to those preventable diseases on which our public and community health agencies are most centered. These disorders attack the organism at an age when it has the least resistance to external influences and offers a most fertile field for the invasion of pathological elements—during childhood. They are contact diseases, being communicated from adults to whom these weaker personalities are emotionally bound and upon whom they are utterly dependent. Unlike typhoid, but like tuberculosis, mental maladjustment is a family disease in that some adult has communicated it to the child by prolonged and repeated exposure.

The communicability of adult reactions, healthy or unhealthy, is brought about through the child's mental mechanisms, which largely determine his acquired psychic patterns, his emotional responses to stimuli, and his capacity to deal with reality.

Identification with his elders and introjection, or the inclusion of environmental factors, such as parental beliefs, prejudices, fears, ideals, and customs, are as natural processes in childhood as growth in height and weight. Children may not imitate adults in the mental content or idea, but they react to it by emotional responses. Ideational material is largely determined by the feeling tone, and by the emotions experienced during the learning process. Inherent energy is apparently transmitted through the germ cells, but the direction of its course is laid out by the intensity of the enviromental impacts. Inhibition of this instinctual force sets up a child's abnormal reactions to his parents, authority, and reality.

Unfortunately, the physiological explanation of inhibition and frustration is unknown. If we could discover the exact chemical process and precise neural reaction when normal excitations of nerves are shunted off in other directions by unnatural checkings, or if we could measure with an "emotionogram" the effect of unhealthy stimulation on the child's central and autonomic nervous systems, then mental hygiene would be willingly taken over by the medical profession and more readily incorporated in a community health plan. Lacking laboratory evidence, we have to rely on clinical findings. Up to now such experimentation has been done only on chimpanzees and other lower animals. Psychiatry has a wealth of clinical evidence that psychic patterns are laid down in childhood, and are the reactions between an organism and the objects of emotional value. This evidence has come during the past 25 years from the analysis of patients who show the mental scars of misdirected instinctual energy during childhood.

The psychoanalytic and mental hygiene findings came at about the same time and corroborate each other. The child guidance clinics have furnished ample evidence of what adults can do to a child's emotions, for when their attitude toward the child and reality changes, the child's metamorphosis occurs. Likewise, when a neurotic, or problem child, is removed from unhealthy parents and placed in a healthy

environment over a long period, alteration in personality and emotional reactions is shown. The cessation of enuresis, night terrors, tics, habit spasms, anorexia, speech disturbance, fatigue syndrome, and many other symptoms by a change in environmental stimuli, give a clue to the causation. Any preventive measures will have to be instituted with these facts in mind.

The following ideas are offered to indicate *how* a community health program can include the prevention of maladjustment and psychogenic disorders.

In the average city of 200,000 the estimated number of children will be about 110,000. The level of intelligence will not be uniform. Of these, 11,000 will be unable to complete the 6th grade in school, and 2,000 of these will be suitable for custodial care in the schools for mental defectives. Another 11,000 will be unable to go farther than the 8th grade, but can take trade training and be good mechanics. Some 66,000 will have the capacity to complete a high school course, such as college preparatory, general or commercial, and the remaining 22,000 will have the cerebral equipment to graduate from some college. The same ratio is applicable to the adult population. These figures are approximate, but they are not rough estimates. In short, 20 per cent will be of professional caliber, 60 per cent will have the ability of the tradesman, skilled artisan, and "white collar" group, and another 20 per cent will include the unskilled laborer, the farm hand, the uncomplicated-machine operator, and those who will never be able to assume financial responsibility for their children, perhaps not even for themselves.

Assuming that the city has adequate health facilities with clinics, hospitals, and a competent board of health, we advise that the mental hygiene department be an adjunct or subdivision of the health department or of a health center. Since psychiatry is a branch of medicine and only that, it is advisable to unite a psychiatric set-up with the other departments of medicine. This affiliation makes its status, function, and purpose clearer to a community. A full-time psychiatrist, social worker, and stenographer will be needed, with a yearly budget of around $15,000.

An important consideration in any community endeavor is the personalities of those serving. Adjustment to life is advantageous in all work, but in other branches of medicine ability can compensate for a multitude of personality defects. The scientist confined to his laboratory is not called upon to mix with his fellow men as much as the doctor in community activity; and the surgeon who operates skillfully can break most of the 10 commandments, yet his ability will always be valued. This is not so with the public official or with the psychiatrist in a community project. As a rule, society expects psychiatrists, like ministers, to be righteous. To measure behavior only as good or bad, rather than as healthy or unhealthy, or to view human conduct wholly from the moral aspect is a remnant of non-scientific medicine. No matter how able a psychiatrist may be, his professional scope is limited if his adjustment to social customs is not as the community would have it.

The emotional reaction of patient and doctor, the psychoanalytic transference, is one of the most valuable instruments in a physician's armamentarium, and shows up positively or negatively in every doctor-patient relation. The same emotional situation occurs in a community's attitude to those from whom it seeks help. A well adjusted staff, with minimal defense mechanisms and adequate social adaptation, integrated with the group

life, has an invaluable asset in making mental hygiene understood. Its work will then be more than "something that some doctor has started."

Approximately 3 months are needed to learn from state hospitals the number, type, and name of cases which have come from the locality during the past 5 years, and to get from the physicians as much information as they can give about the extramural cases of personality disorders—whether acute emotional episodes or chronic paranoid trends. While the psychiatrist is meeting the doctors, the social worker can seek facts from the courts and the schools about the social offenders and problem children, together with the types of offense. During this time the psychologist can correlate this information and note prevalence in families.

This preliminary survey gives the psychiatrist more than a casual acquaintance with the community and its problems, and, no less important, the community meets the staff. When any locality knows the personnel and reason for a health set-up, it is more in accord with its purpose. By understanding the nature of a mental hygiene project doctors, public officials, business men, teachers, clergy, and the general population are less on the defensive and accept it more objectively.

Offers to explain mental illness and the function of psychiatry can be made to various organizations, such as medical societies, educational groups, social agencies, church boards, men's and women's clubs, police departments, and chambers of commerce. This will be the psychiatrist's principal work during the first months. As education of society is necessary for all disease prevention, the psychiatrist will be the instructor in mental health, teaching it in the language that his audiences can understand.

A key position in a community is held by the visiting nurses and social workers. By virtue of their positions and the nature of their work, they have a close and constant contact with the family life of those who are not guided by their doctor, or who are under the supervision of social agencies, because of economic limitation or faulty social adjustment. The varying potentialities of these people can be made clearer to the workers through bimonthly group discussions and individual conferences with the psychiatrist. Thus the family constellation of those who exhibit signs of emotional abnormality and behavior difficulties is made visible. The psychiatrist can examine the parents and suggest therapy—whether it be more suitable work for the father, birth control for the mother, adequate food for the family, adjustment to a mother-in-law situation, or an acceptance of self in one's reality. It may be necessary to test the parents' mental capacity to care for their children, and permanent supervision by a family agency or public department may be needed. At least, a diagnosis and prognosis of the human material can be rendered, as is not done now with our socially dependent class.

In every preventive health activity there are always people who, because of ignorance and its companion, fear, resist any help suggested. Psychotherapy for these unfortunates is impossible until their fear is lessened by more knowledge. The region of the unknown seems dangerous to them and an instinctive self-protection is to avoid danger. The resistance to vaccination, immunization, and other health measures has been overcome only by people becoming familiar with the methods employed, through education inaugurated by health agencies and based upon proven medical facts.

Any preventive work is first adopted by the educated and higher social order of a community. In this group are

the doctors. Society naturally looks to the medical profession for help and information on health. Therefore, a requisite for the prevention of mental illness is that the local physicians know the possibilities and limitations of psychiatry, both in therapy and prevention. This is best accomplished by employing it on cases. A share of the psychiatrist's time—paid for out of community funds—can profitably be allotted to consultation work with other physicians. A psychiatrist, by presenting an occasional and instructive paper at the medical meetings, working *jointly with family doctors and other* specialists, and being interested and coöperative in all health problems, can help to bridge the gap between physiological and psychological reactions. In this way the body-mindedness of our medical thinking will be outgrown, and the physicians can understand the psychiatry that the medical schools failed to teach them. With this knowledge their contribution toward the prevention of maladjustment is unlimited. The patient will not only benefit by therapy, but, equally important, the physician will be better equipped to recognize and control the causative factors in children.

In the prevention of children's diseases much of the doctor's work is accomplished indirectly through the parents, while in our schools the child is met directly. Our educational system is primarily for the pupils enrolled, but often parents learn ventilation and health rules from what the child has grasped in school. Sometimes he, particularly the adolescent, is put in a conflicting position by his parents not agreeing with the teachers.

For this reason the child must feel secure with his instructors and gain some satisfaction from his school accomplishments. Many an emotional conflict produced in the home by rejection, domination, or over-protection, has been lessened by a feeling of safety with his teacher, of belonging to a social group, and of being trusted by the educators with whom he identifies himself. Education, or the development of potentialities, is not accomplished by inhibiting the child's capacities or by expecting him to achieve more than he can. Fitting a child for life is brought about by taking direct account of the organism's ability, and not of the parental hopes and wishes, or the moralist's will power.

To this end the psychiatrist can meet informally with the faculties and give *them a better understanding of the* biological make-up of the total individual, mentioning facts to illustrate that laziness, restlessness, and lack of concentration are not answered by heredity, perversion, or the devil. The conferences can be stimulating and helpful, especially if they are not obligatory.

Following a clearer grasp of maladjustment, vocational planning can be introduced in one school and gradually extended to others. Vocational adjustment takes into account the scientific fact that all men are not created equal in capacities or in opportunities to develop their inherent potentialities. It is a means of having fewer educational misfits, decreasing the rapid turnover in factory, shop, and office, and lessening dissatisfaction in our social structure, with its new political platforms and unrealizable promises every 4 years. Increased knowledge alone shows us the futility and waste of trying to fit a square peg into a round hole. To direct the boys and girls leaving school so that their occupations will be consistent with their intelligence, emotional make-up, physical capacity, and social status, will contribute to the reduction of mental and social conflicts, and it can be done.

The final word of psychological testing has not been said, but the tests

have proved to be as positive measurements of that unknown quality called intelligence as the clinical thermometer is in indicating the severity of disease. The psychologist can sort, in the 8th grade, the simple factory type from those whose ability permits of further schooling. The children with superior ratings on group tests can be advised to enter high school, and the parents who object because of financial or other reasons can be referred to the family physician, the psychiatrist, or a social agency for an explanation of the findings. The choice of further education can be left to the child, with whom it belongs, without family interference—which does not often happen.

Those with low ratings on the group tests can be given manual dexterity and other individual tests to explain the lower score. As the years pass, the test intelligence of the adolescent and young adult group will be on record for future work reference. This and other psychiatric findings can be added to any information necessary for working papers. The clinic or the board of health can act as an employment center where employers can apply and learn of the prospective employees' fitness.

This will be a beginning of psychiatry in industry. A plan of this kind will decrease the frequency of youth attempting wholly unsuitable work with its consequent emotional reaction, and will help them to find gratification in work they can do, which, in turn, is one of the simplest and surest ways of handling the embryonic gangster.

The majority of our adolescent population will be in the various types of high schools, where health education, both for the students and the young parents, can be centered. The psychiatrist can join with other physicians in giving simple talks to parents and pupils, and mental hygiene can readily be incorporated in general health education. The potential parent of the next generation will profit from health instruction, the meaning of parenthood will be better understood, and the ignorance about human behavior and so-called insanity will be decreased.

When requests are made for literature or books, the staff can have available the information suitable to the person's intellectual and educational level, and if the demand warrants it, pamphlets explaining mental health and illness in simple language can be had. Gradually, information on faulty mechanisms, anti-social conduct, purposeless behavior and destructive inhibitions will be as general as is now the understanding of the advantage of milk in one's diet.

In 1930 the Bellevue-Yorkville Health Demonstration instituted an educational program for the nurses associated with the center. The psychiatrist gave only 2 mornings a week to the work, but that time was spent mostly in discussions with the entire group and in individual conferences on the work with the cases. Anyone outside of the staff was welcome to these group meetings, and there was usually some visitor, perhaps a doctor, a social worker, a priest, or a graduate student in some college. After 2 years of work we reported the results at the meeting of this organization in Washington. The program was continued until January, 1934, at which time the city health department assumed the entire financial obligation of the center, and the Mental Hygiene Department, which had been supported from private funds, was discontinued. Gathered from the opinions of the nurses, the teachers, and the families met, together with the results in the other clinics, it can be said that the plan was concrete, workable, and contributory to the lessening of psychogenic and social difficulties.

The lack of community programs for the prevention of mental disorders is not wholly due to the reasons offered by our public health leaders, such as the nonspecific causation and intangible methods, but rather to the same reason that prevents mass prevention programs for venereal diseases, which are of specific etiology and for which the preventive measures are definite and known. Program after program can be laid down, but none will be accepted, no matter how concrete, so long as our leaders think subjectively about the wickedness of sexual instincts and cling to the moralistic idea about the sinfulness of antisocial behavior. Only by education was the somewhat disgraceful term, "pulmonary tuberculosis," substituted for the less innocuous "lung fever." Society accepts some medical facts gingerly but it eventually follows the leadership of the profession. Progress is made after health agencies, public and private, appraise any disease objectively and scientifically. It is brought about by constant mass education, which, like all development, is gradual and questioned. Resistances are always encountered when science uproots our primitive beliefs and lays bare our emotional defenses.

Psychiatry offers no panacea for life's frustrations but looks for the explanation of human behavior as diligently as other specialties search for the meaning of man's less total functions.

The prevention of abnormal behavior is an educational and scientific procedure. It is not peace propaganda, it is not a political campaign, it is not related to capital or labor, it has no reference to any church, it is not a social entertainment.

This procedure coördinates medical knowledge and keeps in mind the totality of the individual. It deals with the imbalance of physiological processes brought about by tissue destruction or emotional conflict. It takes into account the instinctual energy misused and uncontrolled because of grandular disturbance, dietary deficiency, or cellular change; it also works with histologically normal organs *functioning pathologically* as a result of emotional response to parental reactions and environmental influences. It aims toward a sound mind in a sound body.

DISCUSSION

A. O. DEWEESE, M.D.

Director of Health, Kent State University, Kent, Ohio

THIS paper makes the following specific allegations:

1. There is a steady increase of mental disorders, a class of diseases which are almost as endemic as the common cold and about which the causations are as definite.
2. No community has inaugurated as yet a specific and continuous plan for their prevention.
3. The medical profession and boards of health do not yet accept that the prevention of mental and emotional disorders falls within their province.
4. We know very little about the control of organic psychosis but we do know about the control of psychogenic conditions.
5. Due to faulty training, some physicians and public health administrators hold that the etiological factors of psychogenic mental diseases are unknown—therefore not preventable.
6. Some physicians and public health leaders recognize a causal relation between emotional reactions and mental diseases but because of the magnitude of the task do not see any place to begin.
7. Most physicians and public health leaders claim that psychiatrists and mental hygienists offer only theory and no tangible or practical plan for decreasing emotional disorders.

These allegations can, we believe, be proved beyond a reasonable doubt. The last 3 relative to the physician and public health worker may be the fault of the psychiatrists themselves. Psychologists and psychiatrists have spent a major portion of their efforts on the promulgation of theories that mystify the profession as well as the public. They have surely shirked their duty in not pausing long enough to test, prove, and formulate some fundamentals upon which they could all agree. These fundamentals would then be given general scientific approval and serve as the foundation of their specialty and the education of the uninitiated.

The president of one of our large midwest universities recently made a study of his department of psychology. He found that his 6 professors of beginning psychology were each using a different text. The 6 texts were each written to establish the theories of 6 different schools. He called his staff together and asked them if there were not a set of fundamental principles upon which all psychologists could agree. The staff thought that there was. He told them to get together and bring to the next staff meeting a text which incorporated these elementary fundamentals upon which all could agree. Each professor brought the same text he had been using. The president took the position that he did not care what theories or what school of psychology they taught in their advanced classes but all must teach the same text in the elementary courses, and that text must contain the fundamental principles of psychology upon which all psychologists could agree. He asserted that the student had a right to such a text and such an initiation into the field of psychology, before he was asked to grope about and try to keep his sanity in the entanglements of psychological theories. After much discussion with the president, the majority decided upon such a text. Two, however, said they could not teach this text and were excused from teaching the beginning classes.

Physicians and public health leaders have a right to expect that the psychiatrists clarify their field and give some attention to recognized fundamentals upon which a scientific understanding and procedure can be built. Then and only then is it justifiable to make such allegations as the above against the medical profession and public health workers.

Therefore, Dr. Adamson performs a unique service. In so far as is possible in a short paper she states the fundamental points relative to prevention. These principles are simply stated and are agreed upon by all mental hygienists — namely, that psychogenic illness is mainly acquired in childhood; that it is a family disease in the same sense that tuberculosis is, in that some adult has communicated it to the child by prolonged and repeated exposure during a period of weak resistance; that with the understanding that psychic patterns are laid down in childhood, the prevention of psychogenic diseases becomes a problem of leadership and guidance on the part of psychiatrists in the schools and home.

This clarifies the problem, defines the scope of activity, and outlines the point of attack in so far as the responsibility of the public health administrator is concerned. It is at least as clear, and is better defined than our tuberculosis problem was when we began our program of prevention.

With the foregoing allegations and conclusions, the paper proceeds to outline a community health program in the prevention of maladjustments and psychogenic diseases. The plan has the following merits:

1. It is essentially a broad educational program.
2. Its activities correlate the medical profession, the schools, and the home.
3. It is directed by the psychiatrist.
4. It is supervised by the public health department.

This plan of organization clothes the movement with the educational and scientific safeguards essential to its success.

In any new movement, if the highly emotional types are given any opportunity, they do the cause more harm than the conservative element. These well meaning individuals become militant missionaries with a new cure for all human problems. They create illogical and non-scientific ideas and procedures as short cuts to the performance of their miracles. This element has already been a detriment to psychiatry. The phrase prevalent from Maine to California "Have you been psyched?" has in its implications disgusted not only the medical profession but most of the stable population. The plan of organization recommended safeguards the program from such pitfalls.

Any medical educational program not supervised by the medical profession and given the stability of the administration of the public health organization sooner or later runs amuck. It has a period of emotional, hysterical propaganda with wide publicity culminating *in quasi* and pseudoscientific principles and procedure. Sooner or later the public senses the facts, discovers the pseudoscientific principles and goes to the opposite extreme of negative reaction to the whole program. The mental hygiene and mental testing programs of our public schools are even now in such danger.

There is some public demand for the public benefit of psychiatry at public expense. It is interesting to note from news items the various avenues this demand takes. For instance, here is one from the *Akron Times Press*, August 29, 1935: "The Young Men's Democratic Club after hearing a talk by Probate Judge Dean F. May, yesterday adopted a resolution urging the county commissioners to appropriate $15,000 for a mental clinic at the County Home. The club met at the Y.M.C.A. A committee was named to confer with the commissioners."

We can assume then that the following allegations are true, and correct beyond a reasonable doubt.

1. The steady increase of mental disorders is a menace to the health and happiness of the American people.
2. Psychiatrists are agreed upon the essential fundamentals in the etiology and prevention of psychogenic mental disorders.
3. They have established well defined and scientific procedure in diagnosis and clinical treatment.
4. Psychiatry is a branch of medicine.
5. There is public demand for the humane, social, and civic benefits that psychiatry has to offer.

If this be true, then the medical profession cannot be true to its history and tradition if it shirks the leadership and scientific guidance of this phase of medicine, and its administration through the public health organization.

Consumer Demand for Vital Statistics*

The Health Officer's Point of View

LESTER A. ROUND, PH.D., F.A.P.H.A.
Providence, R. I.

THE title of this paper might well have been put in the form of a question, namely, "What use does the health officer have for vital statistics?"

During the past 15 years, while health departments, particularly state health departments, have been expanding rapidly their field of activities, many people are apt to lose sight of the fact that the science of public health was founded and still rests firmly upon vital statistics. There is no branch of public health work the founding of which was not either wholly or at least in part the result of a study of vital statistics.

The so-called "Sanitary Awakening" occurred about the middle of the 19th century. The first medical officer of health in England was appointed in 1847 by the Town Council of Liverpool. In October, 1848, the Corporation of the City of London appointed as its Medical Officer of Health, John Simon, then a young lecturer in pathology at Kings College. John Simon was the prototype of our modern health officer, the first health officer in the modern sense.

Where did Simon get his information regarding the conditions prevailing at the moment and upon what information did he base his acts as medical health officer? From Simon's book on English Sanitary Institutions we find that the death returns of the city registrars were made on Monday mornings and on Monday afternoons they were placed at his disposal, as he says, "in a way which enabled me to complete my use of them during the evening, so that on Tuesday mornings when the weekly courts of the City Commission were held, I was ready with all needful particulars as to the deaths which had befallen the city population during the previous week, and with my scheme of such local inquiries as were to be made in consequence."

From the above quotation we see that the weekly bills of mortality formed the basis for the investigations which he instituted as to the causes and means of prevention of deaths among the inhabitants of London. For John Simon, vital statistics formed the corner-stone of his work.

The 88 years that have elapsed since Simon took office have seen the development of practically all those sciences, such as bacteriology, epidemiology, parasitology, pathology, immunology, sanitary engineering, etc., upon which is based the modern science of preventive medicine and public health. Sources and modes of obtaining information have been multiplied, and yet returns of deaths still form one of the most important sources of information to health officers. All the

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

other intelligence services used in modern public health practice cannot replace the death returns. The standard form now in use in, I believe, all but one of our 48 states contains a mass of information impossible to duplicate by any and all other practical means and supplies the health officers with a great many facts from the practical viewpoint which are unobtainable from other sources.

For certain diseases such as diphtheria, typhoid, and a few others, morbidity reports are quite dependable and reach the health officers in advance of mortality data, but for many other diseases which are public health problems and which in certain parts of the country are more prevalent than diphtheria or typhoid, our only reliable source of information is through the returns of death. It is true that death returns do not give the health officer all the information he desires or needs, but when the medical profession does not report the prevalence of certain diseases with any degree of dependability, the health officer must rely to a great extent upon death returns. To cite only one disease, consider tuberculosis. Previous to 1930 in Rhode Island more deaths occurred from this disease than there were cases reported. I have not attempted to compare corresponding figures in other states. The same condition has in the past prevailed in the other states and if we took the time to inquire, we would probably find it still existing in at least some of our states. Under such conditions we can get but a very poor picture of the situation as regards tuberculosis from the public health standpoint from any source other than the death returns.

I do not wish to create the impression that I am in any way minimizing the importance of morbidity reporting. As a matter of fact, from the health officer's point of view I regard morbidity reports as an integral part of vital statistics. Our vital statistics will never reach that degree of completeness which every conscientious health officer desires until morbidity reports become as complete and accurate as mortality reports. Mortality reports give a two-dimensional picture. The addition of complete morbidity reports to our mortality statistics give the health officer a three-dimensional, stereoscopic picture. The perspective thus created helps to place many objects in the picture in a much more accurate relationship to each other and will help to remove much of the distortion which now affects the picture, particularly if the health office is affected with cerebral myopia.

The health officer is also interested in birth returns, for these statistics constitute the common denominator for the study of all the factors concerned in infant mortality. Our knowledge of infant mortality and our studies of all the factors contributing to infant deaths and the saving of infant lives are vitiated to just the extent to which our records of births are inaccurate.

It is the health officer's duty to determine the size of the public health problems confronting his state, city, or community. It is his duty to ascertain as accurately as possible the progress that is being made in the numerous activities carried on by all up-to-date health departments. He is looking for every reliable criterion for determination of conditions and evaluation of the degree of progress. If there are any faults in his various programs he wants to know where these faults are at the earliest possible moment in order that he may rechart his course and reset his sails for a more direct attack. Even though the advances in public health practice have added other measuring sticks, in all these problems the health officer always has been and always will be dependent to a large extent upon this study of mortality statistics. Mor-

tality statistics are one measuring device with which a health officer cannot dispense. The solution of many of our unsolved public health problems lies in the collection of better and more accurate vital statistics and in the greater study and more accurate interpretation of the vital statistics we already possess.

Mortality statistics was the foundation upon which John Simon founded the modern public health movement. During the 88 years since John Simon began his work vital statistics have lost little if any of their importance. Whatever superstructures have been erected in the past or may be erected in the future, such superstructures will always rest firmly upon a foundation of which vital statistics is an integral part.

Consumer Demand for Vital Statistics*

The Needs of the Epidemiologist

J. A. DOULL, M.D., DR.P.H., F.A.P.H.A.

Professor of Hygiene and Public Health, School of Medicine, Western Reserve University, Cleveland, Ohio

DEMARCATION of the field of epidemiology is becoming more difficult due to a tendency to apply the term not only to infectious diseases, whether or not they occur in epidemics, but also to certain diseases considered to be non-infectious, such as diabetes and cancer. Also it has been applied, correctly, to experimental studies relating to virulence, means of transfer, or resistance. For the purpose of the present discussion, however, it will be understood to denote only the natural phenomena, or natural history, of pathological conditions known to be of infectious origin.

Whipple distinguishes between vital facts, which concern birth, marriage, divorce, sickness and death, and vital statistics, which is the application of the statistical method to the study of these facts. Commonly, however, the terms "vital statistics" and "vital facts" are used more or less synonymously. It will be assumed that the present discussion is concerned with the demand for vital facts, properly collected, collated, and tabulated.

In general, the work of the epidemiologist is twofold. He is the "watchman in the tower" equipped to investigate and take immediate action whenever undue prevalence becomes manifest. Between such events, the intervals comprising most of his time, he is engaged in the study of endemic disease, that is, in research of a fundamental nature such as the determining of sources of infection, methods of spread, or other characteristics; or his efforts may be directed more immediately toward better methods of prophylaxis, as in the study of the efficacy of some immunizing agent.

In his primary function, the epidemiologist depends on vital statistics, upon records of previous and current morbidity and mortality, to initiate his activity. Many small outbreaks are overlooked and large ones not recognized in their early stages, for lack of

* Read before the Vital Statistics Section of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

such records, or failure to utilize them. Case fatality rates have some value in checking completeness of reporting, and should be computed, for the principal diseases, month by month, at least for counties and large cities. Sufficient statistics are now available in most large cities and in many counties to provide fairly satisfactory weekly norms for a few diseases. For this purpose median incidence should be computed, using, for example, the method of Bundesen and Hedrich.

It should be recognized that the degree of completeness of reporting which can be hoped for under the best system of registration will vary with the disease and with its severity. In smallpox, for example, the number of cases reported when a virulent form is present should not be far short of actual prevalence; during mild epidemics a certain proportion will be overlooked. The same general fact is true of diphtheria, scarlet fever, and other diseases; that is, the milder the type the larger the proportion of missed cases.

In research problems, vital statistics are the *sine qua non* of the epidemiologist. Population estimates by color, sex, and age, are in constant demand, and without these other statistics are of little value. On several occasions, it has been necessary for the writer to take a population census preliminary to epidemiological studies, due to the lack of reliable estimates in sufficient detail. This was true of a section of Baltimore some years ago in a study to determine the value of toxin-antitoxin. Also, a block census of Knoxville was made by Dr. Haygood and the writer in studies on typhoid fever. In the first of these instances the count would not have been necessary had it not been for the delay in publication of the federal census. In the second, the city had grown so rapidly as to render quite uncertain estimates based upon a census taken 6 or 7 years prior.

When working in foreign countries, particularly in the Orient, the need for population data is far more acute. In many large areas, no reliable census has ever been taken. Even in the Philippine Islands, there has been no census since 1918, and none prior to this since the American occupation, save the military census of 1905.

In generalizing upon the research of the field epidemiologist it should be noted that many of our most important facts and conceptions relating to infectious diseases still rest solely or chiefly upon evidence obtained in the field. Among these are:

1. The infectious nature and communicability of certain diseases, the etiological agents of which have not yet been discovered.

2. The immunity resulting from an attack of certain common diseases. Perhaps the classical example of this is the proof of immunity conferred by an attack of measles, established by Panum in his study in the Färoe Islands in 1846. Panum was able also to determine other important facts, including the usual period of incubation of this disease.

3. Definite and characteristic differences between diseases with respect to season, age distribution, geographical distribution, and periodicity.

4. The transmission of certain diseases by inanimate objects or by food. A classical example again may be cited, namely, the transmission of cholera by polluted drinking water. Although the name of John Snow is connected most intimately with the Broad Street Pump epidemic, his brilliant statistical analysis of data relating to the cholera deaths in London in 1854 furnished incontrovertible proof of the relationship of these deaths to drinking water. In the appendix to his classical work there is given a list of the names and addresses of fatal cases which he secured from the Registrar General; and also the name of the water company supplying the house. His account is the record of an experiment, set up unwittingly but almost ideally, by commercial water companies; and, as Snow expresses it, "The experiment, too, was on the grandest scale. No fewer than 300,000 people of both sexes, of every age and occupation, and of every rank and

station, from gentlefolks down to the very poor, were divided into two groups without their choice, and, in most cases, without their knowledge; one group being supplied with water containing the sewage of London, and, amongst it, whatever might have come from the cholera patients, the other group having water quite free from such impurity." This is one of the first and most notable contributions of vital statistics to epidemiology.

5. The relative importance of various modes of transmission as actual factors in disease prevalence.

6. The particular conditions responsible for local prevalence whether epidemic or endemic.

Without further expansion, it will be obvious that establishment of these and other facts would be impossible without statistics of population, morbidity and mortality; first, broad statistics which it is the duty of the vital statistician to improve and extend and, second, more detailed statistics which the epidemiologist must collect for himself.

No manipulation of vital statistics can solve the fundamental problem of the cause of epidemics. Mathematically, the usual type of epidemic curve can be reproduced on several essentially different hypotheses; assuming, for example, as did Brownlee, variation in the pathogen, or, as did Ross, variation in other factors. The solution must be sought in the experimental laboratory.

Similarly, no statistician can forecast from a study of previous morbidity and mortality, precisely when an epidemic is to be expected. In influenza, Brownlee was of opinion that there exists more or less regular periodicity, but he recognized fully the inadequacy of available data. In this connection, as in many other problems, it is necessary to think of the future. Only the foundations of vital statistics have yet been laid, even in the most advanced areas. The vital statistician is, therefore, still a pioneer. Upon the success of his efforts to intensify and expand his field, the future of many related sciences, and among them epidemiology, will, to a large extent, depend.

Consumer Demand for Vital Statistics*

The Need of the Child Hygienist

MARTHA M. ELIOT, M.D.

Children's Bureau, U. S. Department of Labor, Washington, D. C.

RECENTLY, as I have had occasion to look over some early reports of annual meetings of the American Association for the Study and Prevention of Infant Mortality, and also the report of the first Conference on the Prevention of Infant Mortality held in 1909 under the auspices of the American Academy of Medicine, I have been impressed with the almost universal demand on the part of the pediatricians, obstetricians, social workers, statisticians, and others who took part in the meetings for more exact and more extensive data on infant mortality. Though previous to the beginning of the 20th century there had been a general awareness of the great number of infant deaths, it was not until the first decade of this century that the in-

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

terest of professional workers in the United States was aroused and concerted action initiated to make available the statistical information which was necessary to stimulate community action for the prevention of infant mortality and the improvement of health conditions among infants and children.

Up to the time of this first conference in 1909, data on infant mortality had been limited to the reports of infant deaths collected in connection with the decennial censuses of 1880, 1890, and 1900, and to reports of infant deaths for a few states and a few large cities. In the law of 1902 authorizing the Bureau of the Census to collect mortality statistics annually, the annual collection of birth statistics was also authorized.

The need for registration of births and the importance of reliable infant mortality statistics based on live births were discussed in the Census reports in 1906; in 1907 the report pointed out that there was no state or city in the United States which had even fairly complete registration of births; in 1909 the need of reliable statistics for the provisional birth registration area and, indeed, for the whole of the United States was reiterated. It was not until 1915, however, when 10 states and the District of Columbia had sufficiently complete registration of births, that the birth registration area was permanently established. Since that time, data of increasing importance to the child hygienist have become available, and today, 20 years later, we have in our infant mortality rates an index for measuring accomplishments in the child health field that is invaluable.

Close upon the heels of this rapidly developing interest in the prevention of infant deaths came similar demands for prevention of maternal deaths, for more accurate and complete reporting of these deaths, and for a better understanding of their causes. Since the accuracy of maternal mortality rates also depends upon the completeness of birth registration, increased impetus was given to the campaign to establish the birth registration area. Furthermore, the close association of prenatal and natal conditions in the mother with the welfare of the new-born infant was obvious, and obstetricians and pediatricians alike were drawn into the activities of the growing child hygiene program.

That vital statistics must be an essential part of the stock in trade of all who are engaged in improving maternal and child health conditions, whether physicians, public health nurses, social workers, nutritionists, or others, needs scarcely to be pointed out. The child hygienist knows, for instance, that the trend of infant mortality rates in his community will be used as one of the measuring rods of the success of his program and that he must be alert to see that the data are as accurate as possible. He knows, too, that one of the most important uses of vital statistics is to interest his public in extending and broadening his program. To do this he must present the data in a form that is graphic and easily understood. Maps and diagrams are of the greatest value for this purpose and will often be more effective than words in educating the public. More material of this sort, giving information on local communities as well as individual states and the United States as a whole, is needed.

The most important use of vital statistics to be made by the child hygienist, however, is in connection with the formulation of his community program. Decisions with regard to the type of service most needed in certain districts or even for the whole area under his jurisdiction may depend to a great extent on the facts brought out by a study of statistical data.

Selection of areas for special investigations, for demonstrations, or for other types of intensive work will depend on the infant or maternal mortality rates or on the rates for communicable diseases or on other morbidity data.

At the present time, when state health departments are planning programs for strengthening their maternal and child health services with funds to be allotted under the Social Security Act, statistics on live- and stillbirths and on infant and maternal deaths are indispensable. The act itself requires that certain allotments of funds be made on the basis of live births, and in deciding how additional allotments will be made from the fund to be distributed on the basis of financial need of the state for assistance in carrying out its plan, not only will live births be taken into consideration but also the need, as shown by infant and maternal mortality rates, and by morbidity as well as mortality rates for diphtheria, tuberculosis, dysentery, and so forth. The use of live births as a basis for allotment of funds is a new procedure which was made possible by the inclusion in 1933 of the last of the 48 states in the birth registration area. Fair and equitable allotment of funds, however, requires that the reporting of data should be equally complete in all states. The birth registration campaigns recently conducted jointly in 24 states by the U. S. Bureau of the Census and the F.E.R.A. have stimulated interest in more complete reporting of births and deaths, and it is hoped that similar campaigns will be conducted in other states in the near future.

Adequate information on which to base the preparation of state programs for maternal and child health services must include not only mortality figures for each state as a whole and for its urban and rural areas by color, age at death, and cause of death, but also detailed statements with regard to the situation in individual communities. Such statements have been prepared from local statistical data in many places for local use. Information on infant mortality rates by counties for the period 1930 to 1932 for the whole of the United States with the exception of Texas is now available in map form, and similar data on maternal mortality by counties for the period 1931–1934 are being compiled by the Children's Bureau in coöperation with the Bureau of the Census. Plans are also under way in the Bureau of the Census for the reporting of mortality data by residence for the country as a whole.

The mortality statistics available are on the whole reasonably satisfactory for the purpose of planning programs or will be when the data on maternal mortality by counties and mortality by residence are available. There are, however, additional data that would be of value to the child hygienist if they could be obtained. There are at present no nation-wide or state-wide data on the relation of infant or maternal mortality to such socio-economic factors as unemployment, family income, and change in economic status, nor with regard to the relation of maternal health to the health of the infant. Had such data been available during the past 5 years, many of the questions in the minds of child hygienists, social workers, and others as to the effect of the economic depression on infant and child health and welfare would have been more easily and more satisfactorily answered. If such data could be made available on a nation-wide basis, added impetus would be given to the whole child health and welfare movement, and the child hygienist would be in a still better position for the organization of activities.

An aspect of vital statistics long neglected and yet of great importance to the child hygienist is the record of

stillbirths. The causes of stillbirth as entered on the certificates are so unsatisfactory and the terms used so poorly defined that it is impossible to learn much about the fundamental conditions that led to the death of the fetus. To study adequately the causes of stillbirths with a view to ultimate reduction in their number, the child hygienist needs not only accurate and comparable information with regard to the items on the present certificate, but more information in regard to conditions in the mother that preceded the death of the fetus. The revised stillbirth certificate suggested by the American Public Health Association's Sub-committee on Accuracy of Certified Causes of Death would provide much of the needed information, and should stimulate interest in the search for causes. Furthermore, completeness of stillbirth registration and uniformity of state laws with regard to minimum period of utero-gestation for which registration of stillbirths is required are of fundamental importance for the reduction of fetal and maternal mortality. Information regarding all stillbirths from the 5th month of gestation onward should be recorded.

An excellent opportunity for improvement in the completeness of stillbirth registration exists in connection with birth registration campaigns. This opportunity should be taken advantage of in the campaigns conducted in the future.

Further information is also needed regarding the prenatal and natal circumstances that precede the death of live born infants, especially those taking place on the first day of life or within the first week. Though prematurity is given as the cause of death in more than half of all neonatal deaths, it is impossible to determine from the birth or death certificates the underlying condition in the mother that led to the premature delivery and was the real cause of the death of the infant. Space should be provided on both birth and death certificates for the entry of information regarding prenatal and natal conditions so that data may be available for infants who survive as well as for those who die.

Revision of the titles under which causes of deaths that occur in the first year of life are classified in the *International List* is greatly needed, especially of the titles that are used frequently for causes of death in the neonatal period. Titles such as congenital debility, which do not describe a medical entity, should be deleted and more titles that are medical entities be substituted for indefinite terms. I appreciate that the difficulty or impossibility of making a diagnosis often accounts for the entry of indefinite terms on death certificates. Complete entry of conditions found in the child would, however, often provide the information not now available for classification of cause of death under titles which would be actual medical entities.

With respect to reporting of maternal deaths, space should be provided on the death certificate for more detail as to cause of death and definite inquiries should be included regarding the prenatal and natal conditions regarding all deaths associated with pregnancy and childbirth. Statistical information is greatly needed with respect to all deaths associated with pregnancy and childbirth and not just those that are assigned to the puerperal state.

To the child hygienist vital statistics are perhaps more important in planning and developing his community program than any other group of facts at his disposal. More use should be made of them, especially in graphic forms, and more data should be gathered and made available to child hygienists and others which will throw further light on the major problems in the field of maternal and child health.

Consumer Demand for Vital Statistics*

The Health Education View

CHARLES F. BOLDUAN, M.D., F.A.P.H.A.

Director, Bureau of Health Education, Department of Health, New York, N. Y.

AT the outset I can testify from many years of experience that there is a considerable demand for vital statistics and it is a demand we should endeavor to meet. But just as any wise manufacturer seeks always to adapt his product to the consumer by studying his market, so should we study the consumer demand and adapt our vital statistics accordingly.

It seems not sufficiently realized that our consumer demand comes from three distinct groups and that each of these requires vital statistics of a special kind. Failure to take this fact into account is largely responsible for the mediocre, uninteresting, and worthless bulletins published by many health departments throughout the country.

First of all, then, let us have clearly in mind the three broad groups of consumers for whom we should prepare vital statistics. They are—practising physicians, students of public health, and the laity.

PRACTISING PHYSICIANS

Let us take them up in order. I have listed the practising physicians first because I regard this group as the one to which health departments should devote their first attention. I have repeatedly expressed the opinion that if a health department can publish only one bulletin, it should be a bulletin addressed primarily to physicians and students of public health. In such a bulletin, vital statistics lend themselves admirably to the presentation of current health problems. They can be utilized to call the attention of physicians to the prevalence of disease, to interesting correlations with which the physicians should be acquainted, and to problems which deserve investigation. I have found them very useful as a point of departure for an informative article on some important phase of public health.

Vital statistics for the purposes just mentioned should be simple, and, as far as possible, illustrated by simple graphs. They should be free from such mathematical refinements as "probable error," "standard deviation," or "correlation coefficient." The tables should be stripped of unnecessary details, and each article should be limited to the presentation of one or two simple facts readily grasped by the reader.

Practising physicians welcome this type of information and are influenced by it. They accept the data and conclusions on the authority of the department of health or other health agency sponsoring the publication.

STUDENTS OF PUBLIC HEALTH

We now come to quite a different consumer group from that just discussed. Students of public health—

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

and under this I include, of course, health administrators—want detailed basic facts. They do not shy at long, dry-looking tables, for they have learned how to extract the nuggets often present in a lot of mere figures. These consumers must have all the available data, must be informed of all the exceptions or inclusions in the tables, all the qualifications.

In a health department bulletin or annual report it is advisable to publish only the detailed basic tables, leaving the publication of scientific analytic studies to special articles in scientific journals.

While the number of those who demand detailed statistical tables is relatively small, they constitute an important and influential part of our consumer group. They should not be overlooked.

THE LAITY

So far as the laity is concerned, its demand for vital statistics comes to us chiefly from the newspapers. Judging by what the city editors ask for when they send their reporters for information, there must be a considerable interest on the part of newspaper readers in vital statistics. Inasmuch as my experience is with the large metropolitan dailies, in which space is very valuable, and inasmuch as the city editors of these newspapers have a keen instinct for what the readers want, this attitude on the part of the editors is significant.

Now just what kind of statistics do the newspapers prefer? Well, for one thing, they all want weekly, a statement of the number of births and deaths. It is advantageous to furnish with this, comparative figures for the preceding week, and cumulative totals for the year and for the corresponding period of the previous year. Besides this, in New York City we furnish figures for a few important causes of death and figures on infant mortality.

From time to time depending on local conditions, some special topic can be treated statistically—the course of a disease over a period of years, the course of deaths from automobile accidents, from suicide, from typhoid fever and the like. Birth statistics always appear to be specially welcome—total births, number of twins and triplets, births by nationality of mother, by age of mother, largest number of births to a mother, youngest mother, etc.

Statistics supplied to newspapers should be extremely simple. The tables should usually be narrow, to fit readily into a single column. On the relatively rare occasions when it is possible to secure extended space for a special feature article, a neat graph can often be used advantageously.

Many of the routine press releases dealing with the health department activities can include statistical data. In this connection, it is well to remember that numbers are more readily understood than rates. If the point can be made by using actual numbers in place of rates, the numbers should be preferred. If rates must be used one should be careful as to the mode of expression. Health officials are so accustomed to the use of rates that they easily forget to write out in full, "per 100,000 of population," or "per 1,000 babies born."

Newspaper statistics should always be timely and as up-to-date as possible. If a particular analysis relates to statistics a year or so old, they may often find prompt acceptance if the introductory statement says: "According to a survey just completed by ...." Naturally, in every case, the material must stand on its own merits; it must have public interest.

In order to secure full use of vital statistics by the newspapers it is important to learn just what constitutes news. There is no better way to do

this than by establishing a friendly contact with some of the local editors, or, in a large city, with some experienced reporters. Discuss matters with them and endeavor to supply sound statistical material along the lines they suggest. However, keep your feet on the ground and do not yield to mere sensationalism.

Is there a consumer demand for vital statistics?

Most emphatically yes!

Consumer Demand for Vital Statistics*

The Field of Demography

WARREN S. THOMPSON

Scripps Foundation for Research in Population Problems, Miami University, Oxford, Ohio

THE interest of the demographer in vital statistics is somewhat less specialized than that of the person engaged in public health work and much less specialized than that of persons engaged in particular fields of public health. The demographer is interested in all the movements of population and in all the factors which are likely to affect these movements, hence, he is anxious to see the best possible all-round collection and tabulation of births, deaths, and marriages. These form a considerable part of the grist for his mill, and naturally he wants the basic materials to be satisfactory. Complete and accurate registration of all *vital* facts is therefore a basic need of the demographer. He must perforce work with less but in so doing his results are vitiated to a certain degree.

One use to which the demographer can put vital statistics is in the forecasting of population growth and changes. In a world in which any planning for the future is done by the community it is essential that population trends be kept track of and that fairly reasonable estimates of growth (or decline) be made. The usefulness of such estimates naturally depends in large measure upon their accuracy, and it goes without saying that this must vary more or less directly with the accuracy of registration of vital facts. I say this because I believe it is now fairly well recognized that there is no *law* of population development by which population growth can be predicted, regardless of the actual vital trends. Again, without accurate death registration we cannot calculate accurate death rates by age, and without these we cannot construct life tables. Also without these age specific rates we cannot calculate the age composition of the future population within limits which will render such calculations of greatest value in planning for old age pensions, for school plants, or for many other enterprises which the community may desire to undertake.

Complete birth registration is just as important as death registration to the demographer. Without this we cannot know the balance of births and deaths and the general trend of population growth. Also without tabulation of births in connection with various factors of population composition, *e.g.*,

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

age, nativity, race, social status, etc., we can only partially know the differences in birth rates between social and regional groups. It is of great importance to know that region A is increasing from an excess of births over deaths faster than region B, or that group X is contributing more to the next generation than group Y. From such data we can hope to learn not only what the differences in the birth rates of different communities are but also what are the factors which control the birth rate. Such information will be extremely useful if ever the community sees fit to venture upon a rational control of population growth. A full knowledge of the differential birth rate is important both because there are differences in the hereditary quality of different groups and also because the educational and social differences between groups of our population may give direction to future social development. It is not surprising, then, that the demographer wants to know the general economic and social background of all children born and of all persons dying. It is important to him to know not only that farmers generally have larger families than lawyers, doctors, and other professional people, but also how much larger these families are, and whether there are significant regional differences. Furthermore he needs to know whether laborers have higher specific death rates than teachers or skilled mechanics, and if so how much higher these rates are. Clearly nothing like an adequate inventory of population movements is possible without very accurate and detailed birth and death registration.

Again, it is important to the demographer to know the age of all mothers giving birth to children, by their nativity and their race. Nor is it sufficient to give merely native born, foreign born, and Negro mothers, nor to lump together Mexicans, Indians, Chinese, Japanese, and Negroes under the rubric "colored." Likewise it is necessary to know the occupation of the head of the family if we are to get any satisfactory notion of the relative rates of increase in different social classes and of the differences in death rates between these classes; and all this information should be available for all sizes of communities. It would be a fine thing, too, if the census classification of occupations and the vital statistics classification could be so related that accurate birth and death rates for different occupational groups could be calculated.

Furthermore the demographer would like to be able to calculate the death rates from the more important causes of death for particular communities, since without such rates he cannot very well understand the differences in their population movements. At present he can do little in this field because of the failure to allocate deaths to usual place of residence for different sizes of communities.

This matter of the proper allocation of births and deaths to usual place of residence is of much greater concern than is generally realized. A good beginning was made some time ago, but most of the gains then made have now been lost. Even at its best, however, this allocation of births and deaths to place of usual residence has never been detailed enough to enable the demographer to calculate age-specific rates for urban and rural populations and for different sizes of urban communities. Nor has it given the details which would permit of calculating these rates for the important nativity and racial groups.

It needs no argument to convince anyone that the increasing use of urban hospitals by rural people is rendering urban and rural rates, as now generally calculated, of no account. Obviously if an appreciable proportion of the

births and deaths of rural residents occur in city hospitals both rural and urban rates are thrown askew and we cannot know just how they differ or even whether they differ at all. The demographer is extremely anxious, therefore, to have birth and death registrations recorded by place of usual residence for all sizes of communities, for all race and nativity groups, and for different social classes. At present all we know is that rural birth rates and death rates are generally too low while urban rates are generally too high and that the rates of most of these other groups differ from one another. Hence, we are not able to calculate satisfactory life tables for different types of communities, to study differential birth rates in detail, nor to calculate occupational death rates with any degree of certainty. In attempting to compare even crude urban and rural death rates at the present time we are compelled to compare states which are chiefly urban with states which are primarily rural rather than to compare actual urban and rural communities. One need scarcely say that such a procedure is far from satisfactory, while in studying many other group differences we are even more at sea. One of the most urgent problems in the field of vital statistics is to secure the proper allocation of births and deaths to the community of usual residence and then to tabulate results in such detail that a true picture of population movements can be drawn. It is devoutly to be hoped that the influence of this organization will be exerted to the utmost to secure these improvements in our vital statistics.

The demographer also feels that there is need of closer coöperation between students of vital statistics and those interested primarily in population. Closer collaboration between officials in these fields would enable both to make their data more useful to the demographer and indeed to the public at large. If the vital statistician knew that he could get the needed population data it would be possible for him to make more elaborate tabulations of his data in and near census years and thus carry forward many interesting and instructive studies at those times. I do not believe I exaggerate when I say that population and vital statistics studies have both suffered considerably from the lack of closer coöperation. This should not be.

The demographer also needs uniform data for all groups from all areas. Unfortunately such uniformity does not now prevail. As a concrete instance of lack of uniformity I may cite the fact that in some states Mexican births and deaths are included with those of the white population, while in others most of them are listed as Mexican. As a result of such confusion we can secure little real information regarding the population movements of either the whites or the Mexicans.

Finally I would say a word about marriage data. These are not as important to the demographer as birth and death data but they are sufficiently important to merit more careful registration and tabulation than they now get. Changes in age at marriage, proportion of remarriages, proportion of mixed nativity and racial marriages, and many other facts with regard to marriage would assist materially in keeping our population inventory up-to-date so that we could evaluate more accurately population growth in relation to the general situation at any given moment. At present we have no federal agency gathering data on marriage and divorce. Furthermore such data as have been gathered in the past are pitifully inadequate to show the movements in this field. It is greatly to be hoped that this type of vital statistics will soon receive a much larger meed of attention.

Consumer Demand for Vital Statistics*

Viewpoint of the Registrar

STEWART G. THOMPSON, D.P.H., F.A.P.H.A.

Director, Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

THE viewpoint of the registrar on the consumer demand for vital statistics often appears to be quite different from that of the consumer. There is a justifiable difference between the viewpoint of the consumer as to what constitutes a reasonable demand and the viewpoint of the state registrar who produces the data to meet the demand. The very fact that this word "viewpoint" has been used is a real indication that the consumer and the producer are getting closer together in their ideas and will undoubtedly make the work of each much more valuable through mutual understanding and hearty coöperation.

We have traveled over many rough roads in the field of vital statistics in this nation. Many of these roads, however, have now been paved or hard-surfaced through education and progress. It is encouraging to note that the state registrars are endeavoring to meet the demands of the consumers and, on the other hand, the consumers are qualifying their demands so that they are more in keeping with what is possible to produce.

In the beginning, the consumer should be advised that the equipment for producing vital statistics varies widely in different states. In some states where adequate vital statistics laws have been in effect over a long period of years and the early work of organization and the set-up of machinery for collecting, filing, and tabulating has become efficient, increased demands from the consumer are welcomed. In many states, the laws are new, the heads of registration districts who are known as local registrars are inexperienced and in most cases are busy men who can only devote a small portion of their time to registration, and in the central office a director (possibly only part-time) with 4 or 5 clerks is expected to handle registration affairs in the entire state. These are conditions which must be faced and, therefore, the consumer demands must be kept within the possibilities offered under such conditions.

A state vital statistics bureau is created and maintained by the tax payers of the state. Therefore, no matter what the consumer regards as of first importance in a vital statistics bureau, the officials in the bureau must first recognize the demands of the citizens of the state who are maintaining the bureau. From the viewpoint of the state registrar, the legal importance of the birth, death, marriage, and divorce records must be his first consideration because of his obligation to the tax payers or citizens.

To meet the need for complete legal data, it is necessary to have adequate laws and a system of registration districts in every state, numbering from

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting, in Milwaukee, Wis., October 10, 1935.

500 to 2,000. There must be a local registrar in charge of each registration district and a state registrar who is responsible for complete registration. Original certificates must be collected from each district every month and delinquent local registrars removed or compelled to render efficient service. This, in itself, is a gigantic task in most states. Thousands of doctors, midwives, and undertakers must be supervised, and those who violate the law brought to a realization of their obligations or taken to court and prosecuted for their failure to observe the laws.

For legal purposes, a certificate should be complete; therefore, all incomplete certificates must be completed either through correspondence or personal contacts. Aside from the field work, in the central office the original certificates received must be carefully studied, corrected, and systematically filed. An alphabetical index is then an important routine which demands an amount of time which is no small consideration. From the records thus made available, certified copies are issued in enormous numbers. The task of searching through these records and issuing certified copies appears to have first place in the routine duties of a state registrar as these records are needed for court cases in deciding inheritances, payment of insurance policies, entrance to school, passports, veterans' compensation, and individuals' rights to accept employment and for many other purposes which have become more or less generally known.

Ten thousand certified copies in a single year for a population of 1,500,000 is not considered a high ratio for this class of work. Can you visualize the field work and office work and the amount of money for postage, clerical help, office rent, typewriters, furniture and fixtures necessary for producing the data outlined thus far? Can you imagine an office force in a state vital statistics bureau of 4 clerks, and expect complete registration and a systematic filing of records for permanent reference? More than one state has an office force in vital statistics thus limited.

Probably next in order is the obligation of the state registrar to the state health officer, state commissioner of health, and workers in the public health program of the state. Tabulations must be prepared for current releases, indicating the number of deaths from preventable causes for cities and counties within the state, and primary information as to the source or origin as well as the exact place of death, as a starting point for the health officer, epidemiologist, sanitary engineer, and public health nurse. This information must be available promptly each month with a résumé of accumulative totals by ages and by months, infant and maternal mortality rates, and disease rates for cities and counties. Annual tabulations for the previous year must also accompany this information for comparisons. Every state registrar who is faithfully performing his duty must have his vital statistics records in proper form for the state board of health at the earliest possible moment each month, as this information is a very important and essential part of the health workers' equipment.

The next obligation of a state registrar is to have a complete transcript of each birth and each death certificate promptly forwarded every month to the U. S. Bureau of the Census. While this part of the work does not require a great deal of time, it is of great importance and is an obligation that should be met very promptly each month. Each registration district is an important unit in a state, and each state is an important unit in national registration. The coöperation of all

will, therefore, build a reservoir of reliable information from which the consumer may draw to meet his demands. The foregoing is a basic set-up for building and maintaining vital statistics records. Demands of the consumer, however, have been growing by leaps and bounds, and to meet the demands, the producer must still struggle for a larger crop and break this crop down into more sub-divisions to keep pace with current demands.

For working rates, authentic population figures must be available. Population estimates by years for cities and counties are necessary. This single item is much more troublesome and has drawn on the nervous energy of the state registrar to a much greater extent than some of the other problems which on first thought might be considered more difficult. Uniformity of rates will be had in proportion to the accuracy of the data collected and the reliability of population estimates used.

Specialized groups have a tendency to get far beyond the advancement of the average mind. Leaders should lead but the leader certainly should not get so far in advance of the average individual that he is lost. A planter may have definite knowledge as to the proper procedure in planting seed but results will be obtained to the extent that he imparts that knowledge to the laborer who does the planting under his supervision. The point is that the seed must be planted properly if a harvest is to be expected. A health officer may know the rules of living but his constituents in the state will enjoy good health only in proportion to the amount of his information that is imparted to the citizens of his state.

In addition to institutes and study groups, it is of vast importance that the public press be used intelligently for disseminating information of an educational nature. This may be accomplished in various ways. One method that has proved its worth is for the state registrar to become personally acquainted with a member of the newspaper staff in his community, cultivate his friendship and good will, have him call daily or several times each week, take him into his confidence, and talk vital statistics. If the state registrar will discuss his problems with the newspaper representative, it will create his personal interest in vital statistics by broadening his knowledge of the information that is available through central registration. A newspaper representative who has a working knowledge of vital statistics will write a much more beautiful and instructive news release than would be possible without his first having become acquainted with the material, its value, its importance, its necessity and its possibilities. To make vital statistics useful and helpful, it is necessary to have a thorough knowledge of the data and if the press reporter is without this knowledge, there is grave danger that more harm than good will result from press releases. A newspaper representative of character who has the confidence of the state registrar will publish helpful facts, educational material, and draw a true picture which will enlighten the citizen of his state.

A newspaper man is looking for news. If a state registrar is too scientific to be interested in news, the newspaper man will publish vital statistics according to his own ideas. There is news in vital statistics and there is material in every vital statistics bureau that is of interest to the public at large. The state registrar, therefore, should have a hand in guiding the press representative in selecting material which is honest, interesting and educational. This phase of the program of promoting vital statistics is of paramount importance.

Safety councils, insurance companies,

social workers, universities, public schools, public speakers, and a host of others keep a continuous flow of questionnaires coming to the vital statistics bureau. Every reasonable demand should be met by the state registrar in so far as it is physically possible. The state registrar is anxious to coöperate in every way. In states where vital statistics laws have been in effect long enough for the bureau to be well established, it is quite simple to cooperate liberally. On the other hand, in states where there is a very small group of workers in a vital statistics bureau and the daily load is heavy, it is often impossible to meet all demands.

The type of program that has been prepared for this Section meeting is an indication of a more sympathetic understanding between the producer and the consumer. When the producer realizes the needs of the consumer, and the consumer realizes the handicaps under which the producer is working, they will then find it not only possible but a pleasure to coöperate with each other. May we all look forward to the time when every bureau in the United States will have adequate funds, sufficient office and field personnel, and competent supervision to make available the necessary information to meet all the demands of the consumer.

Negro Physicians' Memorial Meeting

THE John A. Andrew Clinical Society, organized April, 1918, "for the advancement of Negro physicians and surgeons in the science and art of medicine and surgery and for the study and treatment of morbid conditions affecting thousands of needy sufferers in this section of the South," held its 25th Annual Clinic and 19th Annual Meeting at the John A. Andrew Memorial Hospital, Tuskegee Institute, Ala., April 5–11, 1936.

Some Practical Considerations in B. Pertussis Vaccine Preparation*

GRACE ELDERING AND PEARL L. KENDRICK, Sc.D., F.A.P.H.A.
Bacteriologist, and Associate Director of Laboratories, State Department of Health, Western Michigan Division, Grand Rapids, Mich.

IN the preparation of all bacterial vaccines, the essential problem is the same—to make available the specific antigens in a product which is safe for injection. But even the simplest preparation—a killed suspension of the bacteria concerned—involves innumerable technical difficulties. Before there is any basis for expecting satisfactory results, the requirements for an active vaccine must be determined and met. It seems entirely possible that failure at this point is responsible for the irregular, unsatisfactory results of various workers with *B. pertussis* vaccine—results which led to its omission from the list of *New and Non-official Remedies* of the American Medical Association in 1931.[1]

Recent reports, especially those of Madsen,[2] Sauer,[3] and our own,[4] in which more encouraging results have been obtained, emphasize particularly the need for using antigenically active cultures. A basis for considering this of great importance is found in the bacteriological studies of several workers, more recently by Leslie and Gardner,[5] Lawson,[6] and Shibley and Hoelscher.[7] In order to have clearly in mind the essential features of the preparations in use for these more recently reported studies, certain details of preparation and dosage are compared in Table I. The Kreuger antigen,[8] an extract of *B. pertussis,* is not included because it is outside the realm of the present discussion, which is concerned only with suspensions of whole bacteria. Future work may develop a more nearly optimum antigen for pertussis immunization. The immediate need however is an adequate trial of the whole organism suspension to form a basis for judging other preparations.

In comparing the 3 products in the table, it is seen that they are essentially similar. Each is made from "recently isolated" *B. pertussis* cultures, presumably Phase I, grown upon potato-glycerin agar enriched with blood. Each vaccine is standardized to 10 billion organisms per c.c. and is killed with a chemical agent. The chief difference between Madsen's and the other two workers' is in dosage, Madsen using a total of only 2.2 c.c. as compared with the 7 or 8 c.c. given by the others. The other differences are in kind of blood used to enrich the medium, in certain details of seeding and harvesting, and in choice of a killing agent. There is no experimental proof that these differences have any marked effect on the final product.

Last year we [10] discussed some of the basic problems connected with *B. pertussis* vaccine including choice of cul-

Individual doses	I 0.5 II 0.7 III 1.0	I 1.0 + 1.0 II 1.5 + 1.5 III 1.5 + 1.5	I 1.0 II 1.5 III 1.5 IV 1.5 + 1.5
Interval	3 to 4 days	1 week	1 week

* Formula given by J. J. Miller [9]

tures, kind of medium, harvesting and washing of suspension, and standardization and testing of the final product. Certain inherent difficulties in the procedure were recognized. The experience of another year has called to our attention certain points which have been of practical value in our own work.

In the choice of cultures we have emphasized the importance of using those having Phase I characteristics. While these constitute most of the cultures isolated from patients with whooping cough, we should not lose sight of the possibility of an occasional atypical or related strain being encountered. We have isolated 9 cultures from patients with whooping cough which did not have all of the characteristics of Phase I *B. pertussis* but showed certain relationships to *B. bronchisepticus*. These cultures will be more completely described in a separate report. It is of interest that 1 of these strains was isolated from a vaccine-treated child who had clinical symptoms of mild whooping cough. We do not know as yet the significance of the finding of these cultures in relation to specific immunization but they do raise a question which requires further study. In the meantime we adhere strictly to the use of only Phase I cultures in *B. pertussis* vaccines.

An important practical problem in the preparation of the vaccine is *increasing the yield*. We have tried the addition of various substances to the Bordet-Gengou medium. Of those used, including lactic acid, cysteine, starch, yeast, and various carbohydrates and peptones, proteose peptone had the most marked effect. The

addition of 1 per cent of this peptone to the base medium, all other details of procedure remaining unchanged, approximately doubled the yield on the first sub-culture. In order to determine any possible effect upon the state of the organism, comparative agglutination tests and rabbit skin tests were made on the 10th successive sub-culture. No change in the organism could be detected by these tests. Colony appearance including hemolytic zone were typical on first sub-culture back to the unmodified medium. However, since the growth on the peptone medium is quite heavy, the cultures tend to die rather rapidly when stored, and stock cultures are kept with greater safety on medium without peptone. Adaptation of the organism to the peptone medium is not necessary. The first sub-culture seems to grow as heavily as do later ones. Subsequent trials with neopeptone showed it to be as effective as the proteose. Bacto peptone does not appear to increase the growth.

In connection with increasing the yield, the importance of a *heavy inoculum for seeding* cannot be too strongly emphasized. In early lots of vaccine we used the growth from 1 slant to plant 1 500 c.c. Blake bottle but found a heavier inoculum was needed. We now use the growth from the regular vaccine bottles or flasks for seeding—1 bottle yielding sufficient growth to plant 6 or 7 others of the same size. If 500 c.c. Blake bottles are used, the inoculum per bottle is approximately 3 c.c. of a 10 billion per c.c. suspension.

Another factor of importance in increasing the yield is the *extension of the incubation period* from the usual 48 hours to 72 hours, at which time the culture's growth is at its maximum. Beyond the 3rd day the growth becomes more adherent to the medium, making harvesting difficult. In order to detect any possible change in a culture incubated for longer than 48 hours we compared suspensions of a culture incubated for varying periods up to 6 days. The agglutinability with Phase I serum and skin test reactions in rabbits were practically the same. The suspensions were tested also for virulence. An experiment using 18 mice indicated no marked loss in virulence with longer incubation periods until 5 to 6 days—the suspension from the 6 day culture killed none of 3 mice while the 72 hour culture killed all of 3 mice. The 72 hour culture appears to be at its height with respect to cultural characteristics, ease of harvesting, and quantity of growth and therefore is being used for vaccine production.

Standardization of the strength of the final suspension has received considerable attention. Several methods of adjusting the suspension to 10 billion organisms per c.c. have been tried. Widely divergent results, even by the same individual were obtained with counts both by Wright's method and by direct counts in a Petroff-Hauser chamber. Only by averaging an extended series of counts on any particular suspension can one hope for a relatively accurate result.

Not satisfied with counting as a routine procedure, we tried the *Hopkins' method* and found that a 0.3 per cent suspension—that is, one in which the packed sediment obtained by centrifugation represents 0.3 per cent of the total volume—was comparable to a 10 billion suspension as determined by a long series of counts. Our first observations on a number of suspensions showed that repeated Hopkins' tube findings on the same lot of vaccine checked closely, and the method seemed practicable. Since then, we have had several lots of vaccine that could not be standardized in this way as the sediment would not pack

tightly in the tube and the supernatant fluid remained somewhat cloudy even after prolonged centrifugation. As a further disadvantage of this method, the suspensions to be standardized had to be adjusted by turbidity to approximately 10 billion per c.c. before testing by centrifugation, if uniform results were to be obtained. For example, if a suspension giving a Hopkins' tube reading of 0.6 per cent is diluted 1:2 and retested, it does not give the 0.3 per cent reading that one would expect but one below that figure.

We thought that possibly adjustment according to turbidity would assure more uniform preparations than the other methods tried. After adjustment of many suspensions we adopted a technic which requires comparison of several dilutions of the vaccine under test with a graded series of turbidity standards. These standards are prepared from a *B. pertussis* suspension which has been standardized according to a series of counts and Hopkins' tube determinations. It is important that the standard suspension be prepared under the exact conditions of the vaccines to be standardized. For example, a 10 billion per c.c. standard prepared from a washed filtered suspension might not be comparable in turbidity to one prepared from an unwashed suspension which has retained some opacity due to medium products.

We believe that a turbidity method properly carried out is as practicable and reliable as any other so far proposed. It is significant that others who have given this matter consideration have come to a similar conclusion. In the *Annual Report* of the Division of Laboratories and Research of the New York State Department of Health for 1933, Dr. Lyall states that the standardization of suspensions of *B. pertussis* by turbidity had been adopted and that the method had proved dependable.

In *testing the sterility* of *B. pertussis* vaccines certain growth requirements of the organism should be considered. Since *B. pertussis* grows with difficulty, if at all in deep layers of broth, the usual dextrose broth sterility tubes are insufficient for testing this vaccine. We have therefore added to the usual sterility tests, platings of the vaccine on pertussis vaccine medium and on blood agar. These plates are used in preliminary tests as well as in the final tests made from the filled containers. Although the primary purpose in using solid medium was to determine whether or not *B. pertussis* had been killed, we found on several occasions that certain contaminants that failed to grow in

the broth were detected on the plates. This is in accordance with the report of Rosenstein and Levin,[11] who concluded that both solid and liquid media are necessary in testing the sterility of biological products.

The *keeping quality* of the vaccine is an important consideration. We were interested to know whether the antigenicity of *B. pertussis* near its expiration date—should that be placed, as usual for other bacterial vaccines, at 18 months after its preparation—would vary markedly from that of a relatively fresh preparation. We compared some suspensions of varying age as to their agglutinin production in rabbits under the same conditions of injection and testing. The titers obtained 1 week after the last injection are given in Table II.

Seven rabbits injected with vaccines not more than 3 months after preparation gave titers ranging from 1:7,500 to 1:25,000. Definitely lower titers—from 1:2,500 to 1:10,000—were obtained in 4 rabbits injected with vaccines stored in the cold room from 10 to 16 months. Vaccines 7 M and 7 CB tested before and after storage showed the greatest loss in ability to produce agglutinins. As these suspensions were phenolized, the question arose as to the effect of the preservative on the keeping quality of the vaccine. The suspension preserved with merthiolate did not show as marked changes in agglutination titer after storage. However, a series of opsono-cytophagic tests on the same animals showed no such differences between fresh suspensions and the older ones. The really significant point is whether there is a loss of protective power with continued storage of the vaccine. Information can be gained on this point only after we can analyze the cases of whooping cough in vaccine-treated children correlated with the age of the vaccine used.

No attempt is made in this report to give the detailed methods of vaccine preparation which we are using. The outline of technic is included in the manual of methods prepared by Dr. Stovall's committee.[12]

SUMMARY

The addition of proteose or neopeptone to the base of Bordet-Gengou medium has been found to increase the growth of *B. pertussis*, thereby increasing the yield for vaccine. Other factors which have been found to influence the yield favorably are the use of a heavy inoculum for seeding and an incubation period of 72 instead of the usual 48 hours.

Comparative tests indicate some decrease in the ability of suspensions more than a year old to produce agglutinins in rabbits, compared with relatively fresh suspensions. No particular difference due to age is indicated by opsono-cytophagic tests. Information is lacking as to the correlation with protective power.

Mention is made of a small group of cases of whooping cough in which *B. pertussis* was not isolated; the organisms isolated had certain characteristics of *B. pertussis* but were definitely related to *B. bronchisepticus*. The question is raised as to the possible significance of these cultures with respect to specific immunization.

For standardization of the final product, it is suggested that under the specified conditions, turbidity comparisons with a graded series of dilutions of a standard suspension give relatively uniform and reliable results. In the testing of the final product for sterility, the use of plates of pertussis vaccine medium and of blood agar in addition to the usual sterility broth is suggested.

Health Code on National Basis

APPOINTMENT of 8 health officers to an advisory board which will aid in formulating a standard public health code was announced on April 18 by the U. S. Public Health Service. The aim is to assure the coöperation of cities and towns in a project sponsored by the Treasury Department.

Chief benefits from the formation of such a code will be that every community in the country will have before it a model that has resulted from group and national judgment, giving it a much sounder position.

The advisory committee will hold its first meeting this summer. Those appointed are W. F. Walker, Dr.P.H., Commonwealth Fund, New York; H. F. Vaughan, Dr.P.H., City Health Commissioner, Detroit, Mich.; Hugh R. Leavell, M.D., City Health Officer, Louisville, Ky.; A. D. Weston, Chief Sanitary Engineer, State Health Department, Boston, Mass.; H. A. Whittaker, Chief Sanitary Engineer, State Health Department, Minneapolis, Minn.; J. N. Baker, M.D., State Health Officer, Montgomery, Ala.; Earle G. Brown, M.D., State Health Officer, Topeka, Kan., and George C. Ruhland, M.D., Health Commissioner, District of Columbia.

The first problem will be for each city or community to bring its present health code into conformity with a tentative draft under 5 headings:

1. Organization
2. Control of cases of communicable diseases
3. Control of environment; including food and meat, food establishments and restaurants; milk and milk products; ice cream and other frozen products; water supplies, excreta, insects and rodents, industrial sanitation, schools, swimming pools, tourist camps and homes, barber shops, buildings and premises, smoke abatement, domestic animals and pests, disposal of dead bodies, and nuisances
4. Birth, morbidity and mortality reporting, and the keeping of records
5. Education and publicity and the right of entry

Relationship of the Public Health Nurse to the Part-time Local Health Officer in Communicable Disease Work*

MARGARET G. ARNSTEIN, R.N.

Consultant Nurse, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

ABOUT 1 year ago a study was undertaken in certain representative counties of New York State, to determine the status of communicable disease nursing. This study was instituted partly as a means of gaining the interest and attention of the local workers in the educational program tentatively planned for them; and partly to gather information regarding present practices in communicable disease nursing.

Investigation showed a wide diversity of thought and practice, and it was soon realized that the content of a communicable disease nursing program was so poorly outlined that the relationship of the health officer to the nurse in this work needed definition, as the division of labor between the two was seldom clear. Therefore, early in the study attention was directed to this fundamental problem of interrelationship of health officer and public health nurse, upon which all details of practice and procedure must be based. This paper is a progress report on a study designed for this purpose.

The organization of local health work in New York State with respect to local health officers and public health nurses should be understood. Each incorporated village and each township in a county is required to have a health officer (unless a county health department is established), though occasionally the same physician is health officer for one or more townships. There is no such requirement in respect to public health nurses, and the number of official public health nurses in a county depends upon the wishes of the political governing body, consequently is a very variable quantity. The situation in Onondaga County outside of Syracuse is typical of a good many in the state. It might be considered a good example of the mean, as there are counties with only 1 county nurse for 16 or more health officers, and others with 1 nurse to each 2 or 3 health officers. In this county, there are 4 county nurses, 1 township nurse and 25 health officers serving a population of about 90,000. The 4 county nurses each cover 6 health officers' districts and the township nurse has 2 health officers' districts. This arrangement means that each health officer has only one-sixth of a nurse's time and therefore the relationship is not nearly so close as it would be if their territories were coextensive, and 1

* Read at a Joint Session of the Public Health Nursing and Epidemiology Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

health officer had the full time of 1 nurse whose activities he could direct.

The study was conducted by means of personal conferences with the local health officers, and group and individual conferences with the public health nurses, including school and all other nursing agencies in a district. Districts were chosen which represented different types of population in various sections in the state. One hundred and twenty-three health officers were interviewed in 11 counties which included rural areas in the center of the state where dairy farming is the main occupation, counties in the Adirondacks, a mountainous section, counties on the Hudson River and in Nassau County on Long Island, the last named a densely populated largely suburban area. Sixty-two nurses were seen in individual conferences and 23 group conferences were held with an attendance of about 250 nurses. Discussion was encouraged, and the investigator gained much information in this way. No set form was used in the investigation but an attempt was made to obtain answers to the following questions:

1. What was the relative importance of the communicable disease service in the public health nursing program as carried on in these counties? and what was the amount of actual nursing care given?
2. How many health officers visit all cases of communicable disease reported to them?
3. In how many localities does the public health nurse visit all reported cases?
4. When the nurse does not visit all reported cases, on what basis and by whom are the cases she visits selected? Does she select the cases to be visited, or does the health officer do so?
5. Is the nurse informed of the incidence of communicable disease in her territory?
6. What is the teaching content of the nurse's visit?
7. Who does the following procedures:
    a. Taking throat cultures for diagnosis and for release, of cases, and contacts?
    b. Obtaining typhoid specimens?
    c. Making out epidemiological investigation cards?

Other questions, such as the type of nursing record used, the system of reporting between health officers and schools, the use made of pamphlets giving information about the diseases, etc., were investigated, but these are not pertinent to the particular phase of the study here reported.

The diversity of practice and thinking will be clearly seen in a detailed analysis of the material gathered in these conferences. It was found that the 123 health officers could be roughly classified in respect to communicable disease procedures into 3 groups: (1) 57 who thought communicable disease cases should be visited routinely by the public health nurse; (2) 44 who thought only certain types of cases should be visited, and (3) 22 who did not think the public health nurse should visit any communicable disease cases except in rare instances.

In the first group of 57 were included only the health officers who thought the nurse should be informed of every reported case of communicable disease in her territory and should visit all of them as the health officer's deputy for purposes of instruction and demonstration. She should visit them, making the selection of cases—if all could not be seen—according to the disease, the age of the non-immunes in the family, and other such criteria, rather than according to economic status or the wishes of the private physician.

The second group of 44 thought the nurse should only visit certain groups of people, such as indigents or the foreign born. Among the 44 were included those health officers who were not particularly interested in communicable disease, or had had very few cases in their territory, or saw no great need for a nurse's visit, but were perfectly agreeable and willing to have her visit.

The remaining 22 definitely did not wish the public health nurse to visit

communicable disease cases unless they called her for some special reason. The reasons they did not wish her to do so included the following:

1. That it was not safe to have a nurse visit communicable disease cases and other cases at the same time. (Health officers expressed this opinion either as their own or one felt so strongly by the community that they would not dare oppose it.)
2. That there was no need for a nursing visit; the families could take care of themselves, and understood the regulations. (This same reason was given in a rural section where the people were said to be "self reliant" and in a wealthy residential community where most families had a private duty nurse.)
3. That the health officer himself made all the visits and that he gave detailed and careful instruction, rendering the nurse's visit superfluous.
4. That the families would object to being visited by a county nurse because they thought her sole function was care of the indigent.
5. Personality difficulties between the health officer and nurse accounted for a few of the objections.

Exclusive of the cities, in 9 local health officers' jurisdictions, the public health nurse is informed of every reported case of communicable disease. In 3 local health districts, all in Nassau County, the nurse visits in place of the health officer to instruct the family, and the health officer is called only if there is some special problem. He continues, as in other communities, to diagnose cases which do not have a physician, and to render consultation service to the private physician. In the other 6 districts (all in 1 county) the nurse's visit supplements the health officer's to cases that are quarantined; but when cases do not have to be quarantined, her visit frequently takes the place of the health officer's. Some county nurses recorded no communicable disease visits for a whole year, though probably a few were made and not recorded.

The removal of stringent quarantine regulations on measles and whooping cough has apparently had one rather unfortunate result. Many of the health officers think in terms of legal requirements and faithfully visit and instruct in all diseases that have to be placarded, such as scarlet fever and diphtheria, but as soon as this requirement is removed they stop visiting. As whooping cough has been causing more deaths in New York State than any other common communicable disease, and measles ranks second or third, depending on epidemic conditions, serious consideration should be given to methods which will keep these diseases under the supervision of the health department without imposing unnecessarily burdensome regulations.

There are those who believe that this is a place where the public health nurse can be of most service, for she can instruct regarding nursing care and urge continued medical attention even when there are no restrictive measures to be enforced; but in most instances the nurses have not recognized this opportunity, and in several communities where they visited all cases of quarantinable diseases they ignored measles and whooping cough.

Of 37 nurses for whom complete information was obtained, only 6 were informed of every reported case in their area. Only 4 of these visited measles and whooping cough as a regular part of their service. Three additional nurses were informed of, and visited only cases of quarantinable diseases.

Twenty-four of the 37 said they demonstrated or gave care where necessary, but they had no figures on the number of cases given care, and in some instances it was apparent that according to the nurse's judgment the need arose very seldom in the course of the year.

It is interesting to note that only 13 were ever called upon to make epidemiological investigations. It is hard

to know whether they are not used in this service more often because of deficiency in their basic training, or whether a nurse's investigation is inadequate due to the fact that she has so little practice.

Equally interesting is the fact that all 37 take an active part in promoting immunization against diphtheria. This might well be credited to the activities of the State Department of Health and other state-wide organizations, for in New York State as in other parts of the country a definite intensive drive was carried on to promote diphtheria immunization. The element of competition has entered in as this is a fairly easily measured service, and communities, local health departments, and public health nurses have vied with each other to obtain the best record.

One wonders whether one interest must necessarily crowd out others or whether a well balanced program could not be "sold" to the communities if the same method were used and the same amount of effort put into the undertaking.

In trying to analyze the reasons why communicable disease seemed in many instances to be the stepchild in the nurse's activities, though in theory of public health nursing it has its full share of emphasis, both historical and practical reasons were found. The practical problem lies in the fact that this is an emergency service which requires a visit to the case on the same day as it is reported, and if a nurse is covering a whole county—as was true in certain counties—she obviously cannot render this type of service; but this does not account for the other counties where nursing service was fairly adequate. Here the nurse's neglect of this service could be explained partly by her own feeling of insecurity due to her lack of knowledge of communicable diseases, which goes back in many cases to the absence of practical experience in communicable disease work in training.

The history of the development of public health may also have had an influence on this phase of nursing work. The part-time local health officers began their work when sanitation and control of communicable disease were the main functions of the health department. The nurse coming later, as the first full-time health worker, when the conception of public health had grown to include preventive and educational work in the maternity, infancy, child hygiene, and tuberculosis services, started her activities in these services that were not already being covered, leaving communicable disease in the hands of the health officer. There was also an idea prevalent, which still exists in the otherwise more progressive communities, that it was not safe for the nurse to visit communicable disease cases and other cases at the same time, though not for many years has this idea prevailed in regard to physicians.

There is one other reason which is closely connected with the fact that the health officer remained a part-time worker while the public health nurse devoted her full time, thought, and energy to the development of her work; that is, that in fields where she was not entirely dependent on the health officer, where she could find her own cases, plan her own program, and then simply submit it to him for approval, she has forged ahead. In the communicable disease service cases are reported to him and unless he wishes her to visit them she has no way of even knowing of their existence. Right or wrong, she has been able to develop her infant welfare and her prenatal services, and other similar services, largely through her own effort, but in communicable disease work where she is so much dependent on the health officer, she has stood still or gone backward.

The original purpose of the study was to obtain information regarding certain phases of communicable disease nursing, but questions much more fundamental than those originally outlined were raised. The immediate teaching program had to be changed, and further study of the whole program was indicated. Plans had been made to concentrate a great deal of effort on teaching nurses how to make epidemiological investigations, but it was found that very few ever made these investigations, and that before detailed instructions in record taking were given it would have to be decided whether this was a proper function of a public health nurse. It was found that there was a complete diversity of opinion on what the nurse should do, ranging from the 2 counties where neither the health officers nor the nurses considered communicable disease part of a nurse's work to the communities where the nurse visited all cases of communicable disease and the health officer only visited for special reasons.

There was also a difference of opinion on what should be done for a case of communicable disease by the health department. In general, there has been a change in conception of the work of the health department in this service from what might be called police work, to educational work. The public health nurse has been especially trained to do educational work in the home, and for this reason, with the more recent emphasis on the importance of care and education in communicable disease control work, she should perhaps take an increasingly important part in the program.

The conclusion was that there were a great many questions regarding policies and practice which had to be answered before an ideal program could be set up.

The first and all inclusive question is, What should the nurse do in a communicable disease program? To be more specific:

What responsibility has she in reporting cases, in selection of cases to be visited in education of the community?

Is her responsibility for the service such that she ought to be informed of every reported case whether she can visit them all or not?

Should a trend toward more nursing home visits for instruction and investigation be encouraged?

Should the health officer be urged not to delegate to the nurse some of the home visiting and instruction done by him in the past?

Should the nurse make epidemiological investigations? If so, should she make all of them, or only certain ones? When and for what reasons is the line to be drawn?

In short, what is the ideal division of labor in this service between health officer and public health nurse?

The fact that the results of this study have to be framed in the form of questions shows how poorly defined the communicable disease nursing program has been, especially in those aspects that border closest on the health officer's work. Disagreement not only in practice but also in theory was found among nurses and health officers interviewed.

While this is a report of conditions found in New York State, it was thought that similar conditions might prevail in other states faced with the problem of coördinating the part-time local health officer's service with the public health nurse's, and, therefore, it would be of more than local interest.

During the coming year an attempt is going to be made in New York to answer these questions by trying different programs in the field and studying their action and the results.

A Sequel to a Public Health Ruling Concerning Streptococcic Mastitis*

C. S. BRYAN AND G. J. TURNEY

Michigan Agricultural Experiment Station, East Lansing, Mich., and Department of Health, Lansing, Mich.

THE state law defines milk as the normal lacteal secretion of one or more healthy cows. This indicates that market milk should be produced only by disease-free cows. Furthermore the average examination of normal cows' milk, as compiled from the results reported by numerous investigators, does not denote the presence of streptococci of mastitis. A survey was made in October, 1933, to determine the condition of raw market milk, in the city of Lansing, in so far as the presence of streptococci of mastitis was concerned. This check-up was made by culturing the milk in a differential medium containing 1–150,000 gentian violet which permitted development of the streptococci, but inhibited many other bacteria.

At this time 20 dairies were selling raw milk in Lansing; 18 were producer distributors, while 2 bought milk from a few farmers and distributed it in addition to that produced on their own farms. In the initial check-up streptococci of mastitis were found in the milk from 18 of the dairies, but not in the milk from 2. The check-ups were started in 1933 and continued at intervals to the present. These results are presented in Table I and will be discussed later.

The prevalence of streptococcic mastitis among the herds was such as to warrant further attention. The following facts were deemed sufficient to permit the City Board of Health to do something about the situation:

1. In certain cases streptococci that cause mastitis have been found to be the cause of human infection. This includes the *Streptococcus epidemicus* as well as other streptococci of human and bovine origin that cause mastitis. The human infection usually takes the form of septic sore throat epidemics when *Streptococcus epidemicus* is concerned and individual cases of sore throat together with further complications when streptococci of bovine origin are involved. The city consumer as well as the farm consumer is exposed to this possible health hazard when streptococcus-infected milk is used in the raw state.

2. When streptococcus infection is present in a herd there is always danger of spread. It is important that the dairyman eliminate the infected cows from the herd if he hopes to produce a high quality milk and reduce his herd wastage.

3. The bacteriological quality of the milk produced by infected cows has a high bacteria count, poor methylene blue reduction test quality, high leucocyte content, and high chloride content which gives rise to a salty taste; in addition abnormal odors of producers' milk have been traced to the presence of excessive amounts of infected milk in the supply.

4. Since this work was started, Shaw and Beam[1] have reported that mastitis-infected cows produce 22 per cent less milk and 24

* (+) streptococci of mastitis (—) streptococci of mastitis not present

per cent less fat than normal cows. This is sufficient to warrant some action on the part of the producer to cope with the disease.

In an effort to increase the quality of raw milk and reduce any possible health hazard the Lansing Board of Health passed a ruling reading:

> All raw milk sold in the City of Lansing must be produced by cows free from streptococcic mastitis (infectious mastitis) as determined by two weekly tests by the microscopic method described in *Veterinary Medicine*, 30, 4 (Apr.), 1935. Animals producing such raw milk must be tested every 6 months thereafter and found free of infectious mastitis. Any reacting animals must be removed from the herd.

This was passed in April, 1935, following which the testing of herds concerned was begun.

Each herd was visited and 10 c.c. samples were collected from each milking cow. The udder was wiped with a cloth moistened with a chlorine solution. Several streams were discarded from each quarter, and milk in approximately equal quantities was collected from each quarter by milking directly into the sterile tube. Cows that freshened were tested from time to time. The mastitis found in each herd upon initial test is presented in Table II, as well as the condition 6 months later. Of 316 cows being milked at the time of the check-up in April, 151 were found to be infected while 165 were mastitis-free. These results were reported to the dairymen concerned together with suggestions concerning the elimination of infected animals and replacement with mastitis-free cows. Where animals were purchased they were required to be free from streptococcic mastitis in addition to tuberculosis and Bang's disease.

During the next 6 months an educational program was followed rather than strict enforcement of the ruling. This gave the herd owners time to work out their own problems in obtaining streptococcic mastitis-free herds. Much was accomplished during this time for in the October check-up 237 cows were tested, 20 in 3 herds were infected while 217 in 14 herds were mastitis-free. Two

dairies, which previously sold raw milk, began to pasteurize due to the high incidence of infection in their producing herds. The 3 dairies now having infected cows are expecting to replace them with mastitis-free animals. Fine coöperation was experienced between the dairies and the City Health Department in advancing the standards of Lansing raw milk.

Check-ups were made on the bottled products of dairies selling raw milk (Table I). A study of these data, along with those in Table II, indicate the value of such an examination as a check on the presence of infection in producing cows. In each case where all animals were tested and the infected ones eliminated no streptococci of mastitis were found in the bottled milk. It is of interest to note that streptococci were found in the milk of dairies 3 and 11 following a period during which no streptococci were found. It was found that certain infected animals freshened, and their milk was included in the main supply. When these cows were eliminated the bottled milk again gave a negative result when tested.

The Board of Health of Flint, Mich., has passed a ruling similar to the one here discussed.

SUMMARY

A City Board of Health ruling is discussed which resulted from a pioneer effort to improve the quality of an already good raw milk supply in addition to making it safer.

Animals infected with streptococci of mastitis were eliminated thus estab-

lishing streptococcic mastitis-free herds. Retests were made 6 months later and will be made every 6 months hereafter.

Animals purchased for addition to the herd were tested for streptococcic mastitis before purchase or bought subject to such test.

The producers were greatly benefitted as a result of such testing and elimination of the infected cows, for a higher quality of milk was produced and at the same time a marked decline of herd wastage resulted.

Population of the United States

A POPULATION bulletin released by the Federal Census Bureau, estimates the population of the United States, as of July 1, 1935, at 127,521,000. The estimated annual increase since 1930 has averaged 904,000 per year; this is only slightly more than half the annual increase between 1920 and 1930, which was 1,665,000. The relative increase in population at present is about 0.7 per cent per year.

The annual increase for the United States as a whole was calculated by the use of birth and death figures (after correction for incomplete reporting), and net immigration.

No estimates for states or cities have as yet been given out, because of the difficulty of allowing for the pronounced and irregular population movements during the past 5 years.

Prior to 1930, the bureau has calculated the local populations by the arithmetic projection method. From 1930 to 1934 it has used the method of apportioning among the states and cities, the estimated increase in the country as a whole. This method allows for the fact that the average annual increase since 1930 is smaller than in the preceding decade, but also assumes a rural to urban migration which has not occurred since 1931. This method, like the arithmetic projection method, is therefore believed to be unsatisfactory for states and cities.

The use of current local data are recommended in making these population estimates. When, of necessity, the apportioning method must be used, estimates for cities and states should be checked against school enrollment figures, directory counts, and other local data which might indicate the extent of probable population growth.

A. W. H.

Practical Criteria and Methods for the Identification of Hemolytic Streptococci*

JULIA M. COFFEY

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

BECAUSE of the relatively high incidence and severity of hemolytic streptococcus infections, their control is one of the major public health problems. Although progress has been made in the development of specific therapeutic measures, notably in the anti-streptococcus sera of increased potency and valency now more generally available, the efficacy of such treatment is dependent upon its administration early in the disease and thus upon prompt diagnosis. Similarly, the control of outbreaks of infections such as scarlet fever and septic sore throat necessitates early diagnosis and detection of the source of the incitant. For these purposes clinical and epidemiological observations require the confirmatory data which result from pertinent bacteriological examinations. As a preliminary step in the standardization of methods for the isolation and identification of hemolytic streptococci, tentative procedures[1] for such examinations have been formulated and submitted to the Committee on Standard Methods of the Laboratory Section of this Association.

The choice of procedures is complicated by the innumerable slight variations in the biological properties of this group of microörganisms. Thus, the differences in growth requirements and hemolytic activity—which are especially marked when the strains are first cultivated on artificial media—must be considered both in the preparation of the medium for the plating of specimens and in the incubation of the primary cultures. A 5 per cent defibrinated horse, rabbit, or human blood agar medium, the agar base of which is prepared from beef heart infusion with precautions against the loss of growth promoting substances, furnishes adequate nutritive material even for strains which grow sparsely. This medium also provides the conditions necessary for the detection of hemolysis, since it has a high buffer content and contains no added dextrose, the presence of which inhibits the hemolytic activity of some strains. Furthermore, by plating each specimen in duplicate and incubating these streak plates anaerobically and under partial carbon dioxide tension, growth and hemolytic activity are increased and the need for the more complicated technic of pour plates is avoided. The aerobic incubation of fishings to blood agar which aids in establishing their purity and the tube

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

test for hemolysis serve to eliminate those microörganisms, such as pneumococci, which hemolyze blood agar when grown under anaerobic conditions. There remains, therefore, only the determination of the morphology of broth cultures of those fishings which induce hemolysis to establish the presence of hemolytic streptococci.

In the examination of some specimens, such as blood, spinal fluid, and in some instances purulent discharges, the finding of Gram-positive cocci which form chains when grown in liquid medium and hemolyze red blood cells suffices to establish their etiological relationship. However, the presence in the normal nose and throat and in the udders of cows of hemolytic streptococci, usually considered of little importance in human infections, makes a more comprehensive study of strains from these sources imperative, particularly when they are examined in connection with the investigation of outbreaks, in order that their probable pathogenic relationship may be established. Of the procedures available for this purpose the final hydrogen ion concentration of 1 per cent dextrose broth cultures, the hydrolysis of sodium hippurate, the fermentation of trehalose and sorbitol, and the group-precipitation test yield the most practical differential results.

Each of the biochemical tests serves to eliminate a certain number of strains which appear to play relatively insignificant rôles in human disease. Of the cultures remaining, namely those which produce a final pH of 4.6 or higher in dextrose broth, ferment trehalose, and fail to ferment sorbitol or to hydrolyze sodium hippurate, the majority belong to Group A according to the precipitation test. Since the members of this group have been found to be the strains commonly encountered in human infections, the precipitation test appears at present to be the most satisfactory single differential procedure; however, further information is needed concerning the pathogenic activities of certain other serological groups which have similar biochemical properties and are not infrequently isolated from human sources.

Until the various serological procedures for typing strains within a group are more fully investigated, evidence of the similarity between cultures from carriers and from cases in an outbreak—when both prove to be members of the group commonly encountered in human infections—must depend upon the failure to demonstrate differences between them. In such instances helpful differential data are not infrequently secured by the examination of the biochemical and toxigenic properties of the cultures. Furthermore, the study of the toxigenic characters may prove of very practical value not only in the control of epidemics but also in the treatment of cases, if and when the hemolytic streptococci are classified according to toxin group, and thus in relation to the antitoxic or antibacterial sera, rather than by disease entity.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

WHOOPING COUGH

FOR three successive years we have published articles on whooping cough by Kendrick and her associates.[1, 2, 3] The latest paper [4] summarizes observations on 1,592 children, 712 in the test group, and 880 in the control group. There have been 67 cases of whooping cough, of which 63 occurred among controls.

We have also published the results obtained by Sauer [5] with his vaccine. Among private patients he has obtained 87.5 per cent protection in 458 children, 93.4 per cent among 604 vaccinated at the Health Department of Evanston, Ill., and 95 per cent of 242 children in two orphanages, making an average of 92 per cent protection in 1,304 cases. *The British Medical Journal,*[6] in commenting on his results, speaks of his reports as "commendably cautious." The same publication has given us a careful review of the results obtained in this country as well as others, and concludes that while we must take every possible precaution against testimony which is premature and inadequate, "there is every probability that when the proper dosage of vaccine is known we shall be able to protect children against whooping cough." The Council on Pharmacy and Chemistry of the American Medical Association,[7] in March, 1935, declined to express an opinion on any of the vaccines on the market, saying that they preferred to await evidence which was more positive than that at hand.

Sauer insists that the vaccine is an immunizing and not a curative agent, that several months are required for complete immunization, and that even by the most improved method, about 10 per cent of the treated children contract whooping cough on exposure to infection. In evaluating the usefulness of the vaccine it must be remembered that some 25 per cent of children exposed in epidemics escape even when not vaccinated. As most deaths occur during the first 2 years, he advises early immunization, and believes that the best age is between the 6th and 8th months of life. Substantially, he agrees with the authorities of the Danish State Serum Institute on these points and holds that a freshly isolated hemolytic strain must be used as antigen. For the commercial laboratories licensed by him, fresh strains are supplied monthly.

It is unnecessary to remind health officers of the prevalence and dangers of whooping cough, though there can be little doubt that the average doctor, and no doubt the public in general, regard whooping cough as a more or less trivial disease. Certainly its serious nature is not generally appreciated.

In a series of 54,000 deaths from whooping cough, more than 50 per cent occurred in the first year of life; hence it is evident that Sauer's advice of early immunization is sound. In England, there are some 2,000 or 3,000 deaths in children every year, and in London alone, 40,000 cases occur. In view of its comparatively high mortality, and the fact that treatment is unsatisfactory, in immunization lies our chief hope. Topley [8] advises careful field trials rigidly controlled before wholesale immunization as favored by Sauer can be recommended. Certainly here is a field for the immunologists. We are proud of the commendable work done by members of our Association and given to the profession in our *Journal.*

ROYALTY AND PUBLIC HEALTH

THE journals which are reaching us from England are notable for the tributes which they carry to the late King George, who died on January 20, 1936. The world has joined with the English in their sorrow for a great and most beloved King.

Apart from the tributes to him as a man and a king, special emphasis is laid on his interest in public health. One obituary [1] says, "health, indeed, was a talent with which from end to end of his reign the King was apt to trade." *Public Health* [1] in quoting this says:

In all probability this is true (perhaps it is the case with all who are vowed to the service of the public), and many a time in recent years that in what he did, it was duty and not his own health and strength that His Majesty had in mind, was clear. At the same time, however, if he made sacrifices of his own health it was equally clear that before him always as one of his greater concerns was the health and well-being of his people. That much of the wonderful progress in public health that marks the years of the late King's reign could be traced to His Majesty's expressed wish or initiative is certain. To some extent because of this the loss of King George must be regarded as a personal and very serious one by all engaged in the health service of the public.

The Journal of State Medicine [2] says:

His interest in public health was but one of the many ways in which this concern showed itself. Whether it was in slum clearance and rehousing at home or in the hygiene of a dominion beyond the seas, in the welfare of mothers and children or the care of the sick, his inspiration, wise counsel, and encouragement were a constant source of strength to those whose duty it was to deal with these and other problems of public health and hygiene.

In the midst of the grief over the passing of King George, there is rejoicing that the new King, Edward VIII, shows as equally great interest as his beloved father in the cause of public health. Indeed, it is predicted that the "care of the public health will be a matter of first concern, and that the progress made will be equal to, if not indeed greater than, that which marked the period of the sovereignty of the ruler the nation now mourns." It is a matter of history that he has shown great sympathy for those whose health needs were greatest; that he made personal investigations in many parts of the Kingdom as a result of which he brought pressure to bear which has resulted in the tremendous activity now going on in England in relation to slum clearance, housing, and rehousing schemes. It is possible also that to him is due the recognition of the improvement of the problems of feeding and nutrition of the population. Happy indeed is England to have had father and son who were so much interested in the welfare of their people as successive rulers.

Public Health[3] gives a graceful acknowledgment of the cable sent by the American Public Health Association to the Royal Sanitary Institute on the death of King George. The feeling expressed on the part of our Association was sincere and was deeply appreciated by our public health colleagues in England.

WESTERN BRANCH AMERICAN PUBLIC HEALTH ASSOCIATION

THE Western Branch will hold its Seventh Annual Meeting in Vancouver and Victoria, B. C., June 24 to 27, inclusive. Headquarters are at the Hotel Vancouver.*

Two and one-half days of the session will be devoted to joint meetings with the Canadian Public Health Association, Canadian Tuberculosis Association, and State and Provincial Health Authorities of North America. These three organizations will open their annual meeting in Vancouver on Monday, June 22. The combined efforts of the four organizations will attract a number of the leading public health authorities of this continent. There will be symposia on influenza, and health education; special sessions on vital statistics and public health nursing; discussions on control of rodent plague; industrial hygiene with special attention to silicosis; milk control; venereal disease control; tuberculosis control; the increasing public health importance of cancer and diabetes; Rocky Mountain spotted fever; and plans for a Western Public Health Training School.

The last day (Saturday) will be spent in Victoria, capital of the Province, as guests of Dr. H. E. Young, Provincial Health Officer. Members will be welcomed by the Lieutenant Governor of British Columbia and the Honorable Dr. G. Weir, Provincial Secretary. Trips will be arranged to the far-famed Butchardt's Gardens and to William Head, Dominion Government Quarantine Station. Victoria is a charming city, distinctly Canadian, with its Parliament Buildings, its beautiful port, and its delightful Empress Hotel. It is reached only by boat, either from Vancouver or Seattle.

* See page 548 for travel directions.

Vancouver is a beautiful city of approximately 120,000 population, which is this year celebrating the semi-centennial anniversary of its founding. In it is located the University of British Columbia, with its well developed public health laboratories. It is the Western terminus of the Canadian Pacific and the Canadian National Railways, and is reached from Seattle by way of the Great Northern or by boat. Large comfortable steamers leave Seattle daily at 9:00 A.M., arriving at Vancouver at 6:45 P.M., and at 11:00 P.M., arriving at 8:00 A.M.

The Western Branch meetings have been characterized by a refreshing informality, an attractive program, and a minimum of politics, factionalism, and finance. Starting with 125 members in 1928, it has now grown to well over 1,600, including 123 Fellows, 371 active members, and 1,134 regional members. Members of the American Public Health Association from outside the boundaries of the Western Branch are always welcome at its meetings.

The Canadian Public Health Association will welcome visitors to its sessions.

Dr. H. E. Young, President-Elect of the Western Branch and Chairman of the Committee on Meetings and Publications, and Dr. J. W. McIntosh, Vice-Chairman of this Committee and President of the Canadian Public Health Association, have enlisted every facility for hospitality and scientific interest in their two cities to contribute to the success of the meeting.

The officers of the Western Branch this year are: *President:* Dr. W. F. Cogswell, State Health Officer of Montana, Helena; *President-Elect:* Dr. H. E. Young, Provincial Health Officer of British Columbia, Victoria; *Vice-President:* Dr. J. D. Dunshee, State Health Officer of Idaho, Boise; *Vice-President:* Dr. J. L. Jones, State Health Officer of Utah, Salt Lake City; *Vice-President:* Dr. W. H. Kellogg, Director of State Hygienic Laboratory of California, Berkeley; *Secretary:* Dr. W. P. Shepard, Assistant Secretary, Metropolitan Life Insurance Company, San Francisco; *Treasurer:* W. F. Higby, Executive Secretary, California Tuberculosis Association, San Francisco; *Chairman of the Executive Committee:* Fred Stimpert, Director, State Hygienic Laboratory, Helena, Mont.

EDGAR SYDENSTRICKER

THE death of Edgar Sydenstricker cuts short, in middle age, a career of distinguished achievement. Entering the U. S. Public Health Service in 1915 as a statistician and economist to assist Dr. Benjamin S. Warren in a study of sickness insurance in European countries, he was almost immediately drawn into first one and then another of the field investigations undertaken by the Service, and within a few years had built up a statistical organization which gradually evolved, under his direction, into a permanent research unit, the Office of Statistical Investigations. With the exception of a little more than a year spent in Geneva, completing the organization of the Epidemiological Office in the Health Section of the League of Nations, he remained in charge of the Statistical Office until 1928, when he became Director of Research in the Milbank Memorial Fund, but continuing as Consultant, an active connection with the work which he had begun in the Public Health Service.

As chief of the statistical staff of the Public Health Service he was engaged, either independently, as collaborator, or as consultant, in statistical studies covering a wide range of subjects; epidemiology, industrial hygiene, the hygiene of infants, maternity and childhood, general morbidity and mortality. His chief

interest, however, was in the great mass of morbidity and physical impairment which falls outside of the usual public health records. In this field his work was that of a pioneer surveying the ground which the public health of the future must occupy, and showing its problems in clearer perspective.

Sydenstricker was primarily a student, but his part in public health was more than the collection and ordering of facts. He was profoundly interested in their effective use for the improvement of public health and he did not shrink from meeting squarely the difficulties that stood in the way. A man of sincere and simple modesty, he established the warmest of friendships, and through his personal contacts contributed no less to the moving spirit of public health than to its factual knowledge.

EDUCATIONAL ABSTRACTS *

EDUCATIONAL ABSTRACTS, Vol. I, No. 1, for January-February, 1936, has come to our desk. There is a distinguished board of Coöperating Editors, including representatives from many foreign countries. Education is treated of from 31 standpoints. Our readers will be interested in the Section of Health and Physical Education. There are abstracts in this first issue from 11 sources, all of which appear to be well selected as far as they go.

The format of the journal is quite attractive and patterned after the *Psychological Abstracts* which were the result of many years of psychological research in the field of reading efficiency. The editors propound four questions of the educational profession, the answers to which will help them in their further plans.

We welcome this new journal and wish for it all success.

* Edited by Norman J. Powell, with five Associate Editors. Published bimonthly at Albany, N. Y.

PUBLIC HEALTH EDUCATION*

UNDER our social system it is necessary not only to win the support of the governing body, but to reach into every home, familiarize the people with the functions of the health department, and explain the activities that are being carried out to meet these obligations. . . .

A preliminary step to any advance in preventive medicine or community hygiene is a campaign to acquaint the people with the advantages of the specific methods to be proposed. This presupposes a general and widespread knowledge of the principles of hygiene and community sanitation. This condition does not exist.—W. G. Smillie in *Public Health Administration in the United States.*

To Reach Into Every Home—The above quotations are discussed by Dr. E. E. Kleinschmidt in *Public Health Reviews*, University of Michigan, Ann Arbor, Mich. March 15, 1936. *Free.*

Education of the public in hygienic principles constitutes one of the major problems of the public health administrator today. . . . As a general rule budgetary allowance for such activities are only made when city fathers are inclined to feel generous, or when they believe that a health campaign justifies a temporary expenditure. . . . Thus, in time of distress, the best and often the only contact the health officer has with the public is cast aside.

This contact with the public is often the life-line of many a health department. Leading health administrators, cognizant of the value of this phase of health work, are constantly reminding us of its importance. . . .

This problem, it would appear, narrows down to one of public health salesmanship. Civic pride in good health can and is being stimulated through methods of public education. . . .

Mass methods in public health education are both necessary and inevitable if the problem aforementioned is to be successfully met. And yet, how many health departments are able to extend themselves in this direction? Tradition, lack of social insight into matters of public health, emotional attitudes toward health, poorly subsidized health education programs in the public schools, lack of community leadership in health education—these are the paramount public health problems which must needs be solved today.

Knowing that We May Lead—To know others is set up as an essential for "Leadership in Health Education," by M. C. Coleman, under that heading in *Womans Press,* 600 Lexington Ave., New York, N. Y. April, 1936. *20 cents.*

One essential to leadership with our younger generation is that we have a working knowledge of their mental processes and gear our machinery accordingly. Young people are fully agreed with our modern health education authorities in their belief that health is a means to an end, and not an end in itself. A young woman thoroughly uninterested in your concern over her poor posture comes to life when you casually mention her winged scapulae in relation to a backless evening gown, or to the backless and almost frontless bathing suit. She may be casual over her after-exercise shower and over an unbalanced diet until you suggest that one of these may decide for her whether she will have a complexion like a peach or a prune. Your classes in creative dancing, with bared feet, have made many a girl corn-and-bunion conscious enough to ask what type of shoes she should wear. It does not in the least

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

matter that the girl never suspects that this is one of our objectives in the creative dance; the wisdom of the serpent and the mildness of the dove each has its place in the psychology of the group leader.

Hygeia, April, 1936 — *Hygeia*, A.M.A., 535 N. Dearborn St., Chicago, Ill. *25 cents* a copy.

The public health nurse (her function) . . . Is your child going to camp? (how to choose camp) . . . Store teeth (explaining misunderstandings and complexities) . . . A Health Gadget Wanted—The Tuberculosis and Health Society, 911 Locust St., St. Louis, Mo., yearns for something or other, not expensive, not inappropriate, to be offered to the followers of Captain Hardy:

Thelma Suggett tells us that

Captain Hardy, a jolly, robust character, goes on the air at 4:30 each Saturday afternoon, with the Health Twins, Bob and Jane. At first the programs consisted of an adventure story by Captain Hardy with a subtle health angle. During the past few weeks, however, we found it more effective to dramatize the programs, giving the Health Twins major parts also. A serial is being featured now with fictitious trips to many different countries, the child listeners writing in about what countries they wish to be taken to, in their imagination. Last week, for example, the story was built around the current flood disaster with thrills and adventure, the health angle being the importance of pure drinking water, etc.

We have been sponsoring this program only since December 7, and feel that our radio audience is not now as large as it will be later. Our idea for giving away a gadget to children who write in is, of course, a stimulus to regular listeners and fan mail.

A local radio station donates 15 minutes for this program each week. They coöperate beautifully by providing sound effects, theme song, etc.

This is not the first time that we have sponsored a radio program for children, but we do feel that we have in Captain Hardy the most effective character we have discovered so far.

Send your "give away" ideas direct to Miss Suggett.

Public Health Nursing Exhibited—In the Community Fund campaign exhibition, the Evansville (Ind.) Public Health Nursing Association was presented by the following, as recorded in *Public Health Nursing*, April, 1936:

This exhibit consisted of an immense topographical map of the City of Evansville through which had been made eight rectangular cutouts which allowed the spectator to look into miniature rooms, brightly lighted, in which were scenes representing the various activities of the Association. Each Lilliputian room contained all necessary equipment and furniture complete to the last detail of ruffled curtains and well paper! Dolls dressed as patients, nurses, and doctors were the actors upon the tiny stages.

Illustrated in this exhibit were activities such as a child health conference, a tuberculosis clinic, a prenatal home visit by the nurse, care of a maternity patient in the home, bedside nursing care of the sick in the home, and a demonstration by the public health nurse of milk modification for an infant.

Below each little room there was printed on the face of the map in half-inch type a short description of the activity demonstrated therein. All the windows were numbered, and on a table near the entrance of the booth were mimeographed sheets, explaining

in fuller detail—according to the numbers of *the windows—all the activities displayed* within the tiny rooms. Statistical reports to show the extent of the past year's work were distributed by board members to visitors. The board members were prepared to give out any other information which might be desired about the association. . . .

The map (15 feet x 6 feet) was painted on a three-piece, hinged screen made of beaver board. The health center was made the hub of the map and from this, 12 dotted lines radiated as spokes to each of the outlined 12 nursing districts. These dots were cut out and illuminated from the back through red papers so that they stood out distinctly, making the health center the "center" of all the activities of the association.

Metropolitan Publications — The pamphlets listed below are the more recent publications of the Metropolitan Life Insurance Company, New York, Ottawa, and San Francisco.

Taking Your Bearings (taking the guess-work out of life by means of periodic health examinations) . . . Infantile Paralysis . . . Industrial Dental Service . . . The Baby (has an index) . . . Calling All Drivers (a guide to better motoring) . . . Colds—Influenza—Pneumonia . . . Scarlet Fever . . . Sleep . . .

From the School Health Bureau comes the month by month 4 page *Health Bulletin for Teachers*, and "Supplementary Material for Use in Schools with the Motion Picture Once Upon a Time."

Plain Speaking in Pittsburgh—"Dread syphilis's greatest ally is the moral shudder that accompanies its mention." Thus speaking is *Bulletin Index*, 237 4th Ave., Pittsburgh, Pa. (March 5, 1936; *5 cents*). *B.I.* is an imitation, in form and style, of *Time* if *Time* concerned itself almost solely with local Pittsburgh news and interests. Notable and exceptional is its background and explanatory material.

Quoting a social hygiene meeting in New York:

The biggest barrier in the pathway of ad*vancement and control of these diseases*, the hygienists reiterated, was the fact that social customs taboo their discussion in the press and over the radio.

Gonorrheics and syphilitics, fearing the stigma of social pariahism, still foolishly hide themselves from doctors. Consequently, nobody knows exactly the extent of the diseases, all know that they loom as one of the biggest, toughest problems facing U. S. medicine.

A paragraph of statistics then leads into the Pittsburgh application, the local news, some local facts, and confusion as to a local project.

Probably few cities have such a truth telling medium among its periodicals published less frequently than the daily newspaper.

Health Education, Journal, February, 1936— In *American Journal of Public Health*, Feb., 1936, appeared material on health education, and material useful to those doing some form of health education.

In "Poliomyelitis in North Carolina in 1935," by Reynolds and Knox (page 97):

Since the State Board of Health is state-supported, it was felt that any information on this epidemic collected by the board was public property and, therefore, factual information was made available at all times. . . .

Conclusions: 1. That a daily bulletin, in which facts are given, inspires confidence, secures coöperation, and dispels fear.

In "Poliomyelitis in Tennessee," by Williams (page 103):

Fortunately for the public, the greatest prevalence was noted in the newspapers and practically every case occurring was commented on in more than one paper. . . .

Control measures advocated: 2. Newspaper articles in the form of general preventive measures released from time to time. An effort was made to give facts and at the same time avoid arousing public hysteria.

In "Social Significance of Industrial Medicine," by Kessler, are given suggestions for professional education

(page 162), followed by these references to lay education:

> To overcome the reduction in the life expectancy of the average worker it is desirable that preventive work be promoted. While safety education in industry has achieved a phenomenal success in the reduction of accidents, health education in industry has failed completely in making the worker conscious of any responsibility in the maintenance of his own health. The same technic that has been so successful in combating accidents, bringing the responsibility for accidents down to the lowest executive unit, the foreman, can be applied to industrial health education. It is this same technic that has made child health education successful by making the parent, the nearest executive unit, participate through the medium of Parent Teacher Associations.

" Promotion of Certified Milk (page 180) tells of a campaign launched by producers and milk commissions, information to be secured through Dr. J. A. Tobey, 350 Madison Ave., New York, N. Y.

The group of articles and the editorial (page 181) on poliomyelitis may provide valuable background material in case of another emergency.

Certainly no reader of this department of the *Journal* will fail to read " The Psychological Factors of Health Education," by Galdston (pages 171–173).

An important announcement about certain publications of the former American Child Health Association appears on page 184.

Note " End of Year Publicity " and other topics under " The Open Forum " (pages 186–189).

Under " Books and Reports " (page 199) is a review of " Socialization of Medicine" which may be useful in answering requests for debate material.

" The Dollars Saved " diagram (page 208) might be used in staff meetings, and elsewhere.

Several desirable new members of Public Health Education Section are listed on page 209.

" News from the Field ". (pages 210–214) refers to several educational campaigns.

In Newspapers and Magazines and Radio Talks—*Social Hygiene News,* 50 W. 50th St., New York, N. Y. (March, 1936; *free*), reports as follows:

> Stimulated by the favorable reception of editorial comment on medical facts revealed at the New York Regional Conference in January, the *New York Daily News* recently set a new record for social hygiene education through newspaper columns by printing for its million and a half readers a series of 4 feature articles in syphilis and gonorrhea.
>
> The text, illustrated with photographs and charts, dealt with these diseases as problems of personal hygiene and public health, stressed their dangerous communicable nature, and the necessity of securing early diagnosis and treatment if infected, described treatment, and listed sources of medical advice, and warned against quacks. A second series of 4 articles published a few weeks later, discussed preventive measures, with special reference to prophylaxis.
>
> Captain J. M. Patterson, publisher of the *News,* and Carl Warren, special writer assigned to preparation of the articles, report many congratulatory comments received from physicians and other professional persons. General public reaction has also been wholly satisfactory, as indicated by the many inquiries received by the *News,* the City Health Department, and the A.S.H.A. The articles are expected to be available shortly in reprint form.
>
> Other New York newspapers showed an equally coöperative spirit in reporting Regional Conference sessions. Increased space, accurate reporting, and a gratifying tendency to discard the ambiguous " social diseases " in favor of the scientific medical terms were apparent in leading dailies such as the *Times,* the *Herald-Tribune* and the *World-Telegram.*
>
> Encouraging, too, was the 3 column report of the Regional Conference discussions and accompanying material which appeared in *Time* magazine, issue of January 28 (p. 40). This item and the current series of articles on venereal disease in *Physical Culture Magazine* have been responsible for many additional inquiries and requests for advice, literature, and information coming into the national office.

Meanwhile, a growing disposition to coöperate in public education on social hygiene has been evidenced by the radio stations. Speaking over the N.B.C. network at the annual meeting and luncheon conference of the New York Tuberculosis and Health Association on February 25, Dr. Thomas Parran included in his talk on *Health Security* a clear-cut statement on syphilis as an enemy to health. On February 4 Dr. Snow, broadcasting from WOR on *Keeping the Doctor Away*, also used medical terms. Both of these talks were as usual approved in advance by the radio authorities. It is surely encouraging to all who have public health protection at heart to see the national networks falling in line in the campaign against syphilis and gonorrhea, in which the majority of the local stations long have joined.

In response to a wide request, Dr. Snow's talk has been mimeographed (*10 cents per copy*) and it is expected that Dr. Parran's address will also be made available.

Made by School Pupils—The construction of graphic material *by* students is a particularly good channel for the introduction of health information and ideas into the classroom. Reports of what health agencies and school people have done in this direction will always be welcome for this department.

Two pictures of exhibits are reproduced in *Journal* of National Education Assn., 1201 16th St., N.W., Washington, D. C. April, 1936. *25 cents.* One is a "rotating central display," part of a health exhibit prepared by Detroit students. The other is a glimpse of science exhibit material prepared in Stevens High School, Lancaster, Pa. The making of the latter included all the steps in the study of microscopic specimen and the making of enlarged reproductions.

Visual Education Methods and Materials—Here is a partial check list of visual education possibilities for the classroom, many of which also may be utilized with adults as we find them under varied conditions. The material for the list is found in the outline of a course for teachers, "Preparing Teachers in the Use of Visual-Sensory Aids," by W. A. Yeager:

Blackboard . . . drawings . . . Sketches . . . charts . . . graphs . . . diagrams . . . posters . . . cartoons . . . maps . . . globes . . . stereograph . . . bulletin board . . . album . . . opaque projection . . . duplicating devices . . . objects . . . sand table . . . school journey . . . field trip . . . simple dramatizations . . . puppets . . . marionettes . . . pageant . . . stereopticon . . . still film and film strip . . . slides . . . motion picture.

In *Educational Screen*, 64 E. Lake St., Chicago, Ill. March, 1936. *25 cents.*

In the same issue: "Teaching Safety Through Visual Education," by H. J. Stack. Included are "Standards for Evaluating Safety Materials," covering slides, film strips, and motion pictures.

MAGAZINE ARTICLES

"Compulsory Health Insurance." Editorial which seems to urge that the failure to give adequate medical service to millions of our population is due to "retrogression in the increasing domination of the group spirit," plus "the sacrificing of individual independence." *Saturday Evening Post.* Jan. 25, 1936.

"Hospitals in the Red." An appreciative editorial. *Saturday Evening Post.* Jan. 18, 1936.

"Open Wide," by W. C. Miller, D.D.S. *Collier's.* Mar. 14, 1936. "How to see that your children's teeth fare as well as yours, or better."

"Sensitive Souls," by H. Lees. *Collier's.* Jan. 25, 1936. "One man's meat is another man's allergen."

"A Social Worker's View on Dentistry for the Masses," by D. W. Weist. *Alumni Bulletin*, University of Illinois College of Dentistry, Medical Arts Bldg., Scranton, Pa. Sept., 1936. *35 cents.*

BOOKS AND REPORTS

Disease and Destiny—*By Ralph H. Major, M.D. New York: Appleton-Century,* 1936. 338 pp. Price, $3.50.

There is no more fascinating subject than the ruthless influence of plague and pestilence upon history. There is no subject more neglected by the professional historian, who prates of wars, conflicts, and conquest, with never a word on the romantic conquest of disease; who describes the frequently futile lives of kings, emperors, and adventurers, but overlooks the careers of scientists and sanitarians; who, more rarely, recounts the customs, commerce, and morals of peoples, but fails to mention their hygiene and sanitation. Occasionally, a great epidemic receives passing mention in one of the "standard" histories, but the author seldom realizes that such a distressing event may have altered the course of history.

In this engrossing book a medical scholar reveals the dominant rôle played by disease in the destiny of nations. In 10 interesting chapters he tells the stories of the Black Death and the devastation caused by this bubonic plague; of the destruction wrought by Jail Fever, or typhus; and of the King's Evil that scrofulous monarchs could not cure. He tells of smallpox more violent than the constant wars of the Middle Ages, of membranous croup and malaria, of leprosy and yellow fever. There is a particularly interesting section on hemophilia, or the legacy of bleeding; while the final chapter is devoted to the worst plague of all, syphilis, which afflicted, among many others, the Borgias, Francis I, Henry VIII, Nietsche, and, last but not least, Nikolay Lenin.

All this is told with colorful embellishment, and with due recognition of the plague-riders who were responsible for man's inevitable victories over most of the pestilences that have inflicted him since time immemorial. Occasionally the author attributes the death of a celebrity to a cause not recognized by most of the relatively few medical historians who have investigated the subject, as when he states that George Washington probably died of diphtheria. The best evidence seems to indicate that his death was due to a bacterial infection resulting in inflammatory swelling of the larynx and air starvation. The author also repeats the famous story of the alleged infection of Francis I with syphilis by "La Belle Ferroniere," an incident regarded by most historians as a myth, or as a canard of contemporary writers.

These mild criticisms, if they are valid, do not detract from the excellence of the book, which is a most interesting, well written, and valuable presentation of authentic facts on the profound influence of disease on history. The text is very well printed and profusely illustrated. It can be read with profit and entertainment by all health workers, and it should prove instructive and pleasing to the general reader. It is, in fact, a splendid piece of work. JAMES A. TOBEY

Doctor of the North Country—*By Earl Vinton McComb, M.D. New York: Crowell,* 1936. 238 pp. Price, $2.00.

Autobiographies are always interesting. The one before us is no exception, but contains some things which we believe might well have been omitted.

Every doctor has experiences similar to those mentioned. In a comparatively new country peopled largely by those who are the immediate descendants of immigrants, experiences are apt to be a little more raw than in older communities. One story taxes our credulity. It is hard to believe that an old woman, however stubborn, could have amputated her leg just below the knee "with a few strong snips of the scissors." How did she get through the bone?

In addition to everything else, the author was at one time Health Officer of his city, which he calls "Ourtown." In spite of the hardships described, the book closes on an optimistic note, and the author would not exchange his profession for any other in the world.

Why do so many books these days have an introduction? "Good wine needs no bush."

MAZŸCK P. RAVENEL

The Tuberculin Handbook—*By Halliday Sutherland. London: Oxford University Press*, 1936. 96 pp. Price, $2.75.

This clearly written, well printed book based on 25 years' experience, contains information for tyro and expert about the use of tuberculin in diagnosis and treatment.

When symptoms, and/or physical signs and/or radiological examination suggest the diagnosis of early pulmonary tuberculosis and tubercle bacilli have not been detected in some excretion, the tuberculin test should be used. As this occurs usually early in the disease, the author devotes 23 pages to a detailed discussion of early symptoms, physical signs and X-ray changes. All adventitious sounds and tubercle bacilli in the sputum are considered "late signs." "To sum up, none of the early symptoms, physical signs or X-ray appearances are in themselves, either singly or combined, diagnostic of pulmonary tuberculosis, and the key to their interpretation is in the tuberculin tests."

Agreement with this statement rests, of course, upon the definition of what constitutes treatable early pulmonary tuberculosis. Tuberculin tests are either generic (qualitative) or selective (quantitative), which he holds differentiates between obsolete and latent infection. Many forms of the test (he prefers the intradermic with either old tuberculin or the new purified protein derivative) are generic. If positive he gives the subcutaneous test at once. Only the subcutaneous test when it is positive to a dose of 0.005 c.c. or less of O.T. is selective and indicates activity. Therefore, all reactions to such a dose indicate treatment but not necessarily in a sanatorium; nor need the patients give up work, whereas symptoms, physical signs, or X-rays, may show such to be necessary. It is to be inferred that he treats in this way patients in whom a positive diagnosis can be made only by the tuberculin test. He leads one to infer that focal pulmonary reactions are fairly common when many others find they rarely occur. He interprets slight X-ray changes by the tuberculin reaction and the tuberculin test by the X-ray findings.

He considers tuberculin as "our greatest asset in the diagnosis and treatment of tuberculosis" of every form. He uses small doses at first, and prolonged intervals if reactions occur. He quotes Gillespie's favorable results to prove the value of tuberculin. His idea is to abolish the tuberculin sensitiveness. Nowhere does he mention that allergy and immunity may not be connected.

Full details are given about technic.

The book is readable and written apparently in a restrained manner. He does not refer to the psychological side

of the tuberculin treatment. Many no doubt wish they could share his faith in tuberculin. LAWRASON BROWN

Sanitary Law and Practice: *A Handbook on Public Health—By W. Robertson, M.D., Charles Porter, M.D., and James Fenton, M.D. (8th ed. rev.) London: The Sanitary Publishing Co., Ltd.*, 1935. 968 pp.

The new edition of this excellent work will be welcomed everywhere. The Preface of the first edition stated that it was written to meet the wants of those undergoing a systematic training preparatory to presenting themselves for examination rather than to compete with works on the theoretical aspects of public health.

As we have nothing in this country corresponding to this English system, the book will evidently be of more use from that standpoint in England than in this country. However, we have derived so much from England in the way of public health that one can study her laws, regulations and orders, and the methods of carrying them out with great profit. This book is well worth careful study by all health officers as well as others interested in public health.

The amount of study involved in getting this book together, even if we consider it only from the legal aspect, has been enormous, and speaks a great deal for the industry as well as for the masterly knowledge possessed by the authors. It will be remembered that Dr. Charles Porter is a Barrister-at-Law of the Middle Temple as well as a physician and Health Officer, and no doubt this accounts in great measure for the excellence of the book. It is still known under the name of Robertson and Porter, but for this edition, Dr. James Fenton's name appears on the title page as a co-author.

The idea must not be gotten that it is entirely a book of sanitary law, although it is an excellent reference if one wishes to study the English statutes on the many phases of public health. It is a good book on practice, and contains a tremendous amount of well written and necessary information for the health officer.

The book is excellently printed and has a large number of illustrations. The appendix gives the Housing Act of 1935. A good index adds to the value of the work. MAZŸCK P. RAVENEL

Handbook of Bacteriology—*By Joseph W. Bigger, M.D. (4th ed.) Baltimore: Wood,* 1935. 458 pp. Price, $4.25.

Not only have four editions of this excellent handbook been required in the 10 years since it first appeared, but two editions have been reprinted, and a Spanish edition has been issued, which show that the book has found a place with teachers. Bacteriology is such a rapidly growing science that even specialists find it hard to keep up with all the new things, and a well digested handbook such as this is very useful not only to teachers, but to students.

The present edition has numerous changes. According to the Preface, some two-thirds of the pages have been altered. The greatest changes concern water, diphtheria and typhoid fever. The author continues to recommend "fresh, healthy human hearts" for making the antigen for the Wassermann test. In America, these can be had almost on demand in some of our gang-ridden cities, and our frightful automobile death toll would furnish another constant source provided we were allowed to do postmortems. We cannot help wondering where a constant source of supply is found in England with its wonderfully low murder record and the few fatal motor accidents which occur.

We again find that we can recommend this book. MAZŸCK P. RAVENEL

American Sewerage Practice, Vol. III, Disposal of Sewage—*By Leonard Metcalf and Harrison P. Eddy. Revised by Harrison P. Eddy. (3rd ed.) New York: McGraw-Hill,* 1935. 836 pp. Price, $7.00.

This book deals with the theory of sewage treatment and disposal, as well as the design and operation of sewage treatment plants. Since 1916, when the second edition was published, there have been many developments in the art of sewage treatment which have spread out in so many directions that the authors found it necessary to rewrite completely a large proportion of the text of earlier editions. In making the revision, an effort has been made to devote adequate space to both older and newer processes of treatment and thus to maintain a balance which would be most helpful to readers in general; rather than to devote a relatively large proportion of space to new processes. This has resulted in an increase in the chapters from 20 in the second edition, to 33 in the third edition, without materially changing the size of the volume. The book contains 227 illustrations.

Some of the more important new features of this edition are: Chapters on the characteristics and behavior of sewage and on the pollution and self-purification of natural waters; material on skimming tanks, storm-water tanks, contact aerators and separate sludge-digestion tanks; an outline of the recent developments in chemical precipitation; three chapters devoted to the theory and operation of the activated-sludge process and the general design and details of activated-sludge plants; material on the mechanical dewatering and drying of sewage sludge and on the utilization of sludge gas; chapters on the separate treatment and disposal of industrial wastes and the operation and maintenance of sewage treatment plants; data on the costs of constructing and operating certain features of treatment plants; a bibliography in practically every chapter, listing articles and books on the subject matter of the chapter.

The death of Mr. Metcalf in 1926 left the responsibility for this new edition to Harrison P. Eddy and his associates. In the preparation of this volume, information and data were furnished by many engineers and others throughout the country.

ARTHUR P. MILLER

Introduction to Public Health—*By Harry S. Mustard, M.D. New York: Macmillan,* 1935. 250 pp. Price, $2.50.

In the *Foreword* the author states:

> It is purposely brief and does not concern itself with the details of public health administration; nor does it presume to offer suggestions for classroom or field instruction in any of the specialized phases of public health practice.

The subject-matter has been carefully selected, concisely expressed, and is accurate. Dr. Mustard has had a large experience in dealing with public health operations. The points of view presented in the various chapters are dependable, and this book should be very useful as a ready reference for public health workers.

There are 12 chapters in the book. The first deals with the background and scientific basis of hygiene and public health. Historical references to some who have made significant contributions in this important field are of interest and are stimulating.

It is unfortunate that an attempt has been made to present points of view concerning medical care as a function of public health. Inadequate consideration is given to this very difficult and perplexing problem. The author could have, with profit, made a more careful analysis as to the problem of providing more adequate medical service for all

classes of the population. This might well have been omitted.

Vital statistics and public health organization and administration are discussed in 2 chapters. Appropriate reference is made to the contributions of nonofficial and the public health agencies in administrative practice and research.

The acute infectious diseases are discussed as to causes, factors concerned in occurrence, modes of transmission, preventive measures, relative importance of periods of incubation and of communicability. Attention is called to the part which the public health nurse should play in the control of certain diseases; for example, diphtheria and tuberculosis. The place of the public health nurse in the program for the control of venereal diseases is stressed.

Two chapters are devoted to environmental sanitation and individual hygiene. Sewage disposal, water and water supplies, milk as a problem in sanitation, diseases spread through water and milk, supervision of food supplies, garbage disposal, and sanitary measures for the prevention of insect-borne diseases are considered. Ventilation is discussed with particular reference to variations of temperature and humidity in relation to human comfort and health.

Childbearing and its relation to the public health, the hygiene of infancy and young childhood, and the school health service are dealt with in an interesting and practical way in 3 consecutive chapters. These are the most constructive discussions in the book and should be exceedingly helpful to public health workers. The principal elements in a maternity hygiene program are indicated. The relation which the nurse should sustain to this phase of public health is clearly outlined.

The last chapter deals with non-communicable diseases and stresses the importance of programs for the prevention and control of cancer, heart disease, mental disease, and the relation of these activities to the general public health program.

The subject matter of this book is well arranged, clearly and effectively discussed, and its practical importance should prove suggestive and helpful in administrative procedures. It is a publication which should be particularly useful in teaching public health nurses.

There are several unfortunate mistakes in the spelling of proper names which show carelessness in publication. Otherwise, the printing is excellent.

W. S. LEATHERS

BOOKS RECEIVED

A GUIDE TO HUMAN PARASITOLOGY. FOR MEDICAL PRACTITIONERS. By D. B. Blacklock and T. Southwell. (2d ed.) Baltimore: Wood, 1935. 259 pp. Price, $4.00.

THE INTERNATIONAL LABOUR ORGANISATION AND SOCIAL INSURANCE. International Labour Office, Geneva, 1936. 219 pp. Price, $1.50.

THE SPECIFICITY OF SEROLOGICAL REACTIONS. By Karl Landsteiner. Springfield: Thomas, 1936. 178 pp. Price, $4.00.

GREAT DOCTORS OF THE NINETEENTH CENTURY. By Sir William Hale-White. Baltimore: Wood, 1935. 325 pp. Price, $5.00.

ALCOHOL: ITS EFFECTS ON MAN. By Haven Emerson. (Student's Edition.) New York: Appleton-Century. 128 pp. Price, $.80.

TUBERCULOSIS. By Gerald B. Webb. New York: Hoeber, 1936. 205 pp. Price, $2.00.

SWIMMING POOL DATA AND REFERENCE ANNUAL. Vol. IV. By Earl K. Collins, Editor. New York: Hoffman, Harris. 1936. 128 pp. Subscription, $2.00.

BIBLIOGRAPHY IN HEALTH EDUCATION FOR SCHOOLS AND COLLEGES. By Mary Ella Chayer. New York: Putnam, 1936. 100 pp. Price, $1.50.

PUBLIC HEALTH NURSING. By Mary Sewall Gardner. (3d ed. rev.) New York: Macmillan. 476 pp. Price, $3.00.

CANCER COMMISSION COMMITTEE STUDIES OF THE CALIFORNIA MEDICAL ASSOCIATION. San Francisco: Stacey, 1936. 123 pp. Price, $.75.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Vengeful Providence—Two intoxicated hunters somehow killed, cooked, and ate a rabbit, soon sickened with tularemia, and died. The moral which health educators will have to publicize seems to be: if you must hunt rabbits, hunt them sober.

AMOSS, H. L., and SPRUNT, D. H. Tularemia. J.A.M.A. 106, 13:1078 (Mar. 28), 1936.

Preventing Intranasal Infections—Picric acid in about ½ per cent dilution, instilled into the nostrils of monkeys and mice prevented intranasal infection with poliomyelitis and encephalitis viruses. The prophylactic had no injurious effect upon mice, monkeys or men.

ARMSTRONG, C., and HARRISON, W. T. Prevention of Experimental Intranasal Infection with Certain Neurotropic Viruses by Means of Chemicals Instilled into the Nostrils. Pub. Health Rep. 51, 9:203 (Feb. 28), 1936.

Path of Polio Invasion—Picric acid instilled intranasally tends to protect against intravenous (as well as intranasal) inoculation with poliomyelitis virus, thus apparently confirming the contention that intravenously introduced polio virus gains entrance to the central nervous system via the olfactory tract.

ARMSTRONG, C. Prevention of Intravenously Inoculated Poliomyelitis of Monkeys by Intranasal Instillation of Picric Acid. Pub. Health Rep. 51, 10:241 (Mar. 6), 1936.

Unto the Third Generation—Babies of mothers vaccinated in the recent past were more difficult to vaccinate successfully under the age of 4 months than were those of mothers not recently protected against smallpox. The author wonders whether continuing generations of vaccinated mothers will not finally achieve a smallpox immune people.

BENNETT, J. Parental Vaccination and Transmissible Immunity. Pub. Health, 49, 6:216 (Mar.), 1936.

Health Administration and Housing—Recounting the slow growth of the slum clearance program in Great Britain, this paper will not be very comforting to us who have only begun to scratch the surface of this difficult problem. Adequate housing is a health problem, and it behooves American sanitarians to become conversant with what others have done.

CONNAN, D. M. Public Health Administration in Bermondsley. J. State Med. 44, 3:146 (Mar.), 1936.

Ions and Influenza—This paper seems to be a discussion of the possible relationships between the H and OH ions of the blood, thunder, and influenza. This reviewer became lost in the graph showing "the alkaline tide which may markedly develop in Splanchnic Anabolics upon awakening" and never found out about the thunder.

HAMER, W. H. The Endemic Influenza Prevalence of the Three Years 1933, 1934, and 1935. J. State Med. 44, 3:125 (Mar.), 1936.

"Heart Disease" and Diseases of the Heart—Recording the fact that half the female deaths from heart disease occur after age 69 and one-third of male deaths are in the same category, the author wisely points out that "heart" deaths among the aged should not be considered in the same light as

heart disease deaths among younger groups.

HEDLEY, O. F. The Picture of Heart Disease Mortality Obtained from Vital Statistics in Washington, D. C., During 1932. Pub. Health Rep. 51, 12:285 (Mar. 20), 1936.

Municipal Sewage Disposal—Briefly reviewing the recent progress in sewage treatment, the author includes discussion of cross-connections, garbage disposal, and other topics of interest to sanitarians.

HYDE, C. G. Recent Trends in Sewerage and Sewage Treatment. Municipal Sanitation, 7, 2:44 (Feb.), 1936.

Vitamin A Deficiencies—Testing children for vitamin A deficiency by measuring their ability to adapt vision to the dark, the authors found a quarter of rural children, more than half the village group, and from half to three-quarters of the urban children (depending upon economic level) deficient in that important vitamin. Feeding vitamin A or carotene developed normal adaptability to the dark.

JEANS, P. C., and ZENTMIRE, Z. The Prevalence of Vitamin A Deficiency among Iowa Children. J.A.M.A. 106, 12:996 (Mar. 21), 1936.

Evidence Against Poliomyelitis Vaccination — Monkeys convalescing from paralytic poliomyelitis are uniformly resistant to reinfection whether or not antibodies are demonstrable in the serum, whereas monkeys vaccinated with inactivated agents remain susceptible. The findings indicate that circulating antibodies are a by-product of infection and are not correlated with resistance. The author believes that vaccination though it may affect antibody formation does not produce immunity.

JUNGEBLUT, C. W. The Mechanism of Immunity in Experimental Poliomyelitis. J. Infect. Dis. 58, 2:150 (Mar.-Apr.), 1936.

When History Was Made—Some interesting reminiscenses of the early production and use of antitoxin in this country by the man who did it.

PARK, W. H. The First Production of Diphtheria Antitoxin in the United States. Canad. Pub. Health J. 27, 3:111 (Mar.), 1936.

Scarlet Fever Prophylaxis—Ten graduated doses of scarlatinal streptococcus toxin achieve immunity with fewer and less severe reactions.

RAPPAPORT, B. Active Immunization to Scarlet Fever with Less Reaction. J.A.M.A. 106, 13:1076 (Mar. 28), 1936.

About California's Flyer in Social Medicine—Provisions of the defeated Californian health insurance bill are explained as well as their probable effect upon public health nursing. A committee will report a new bill for the consideration of the next legislature.

RUSSELL, M. E. Health Insurance in California. Pub. Health Nurs. 28, 3:148 (Mar.), 1936.

The "Kate Adams" heading toward New Orleans. This is one of the few remaining side-wheelers.

NEW ORLEANS, THE CONVENTION CITY

As New Orleans has been selected for the Annual Meeting of the American Public Health Association to be held October 20 to 23, many, no doubt, will be anxious to learn some points of interest regarding our Convention City.

New Orleans has been called by many tourists, "America's most interesting city." Interest, of course, is a subjective term, and its breadth and depth of meaning depend on personal reactions. To most people the "home town" is obviously and naturally the most interesting place in the world, but next to it there are some places which have always offered to travellers points of unusual interest. Such a place New Orleans has been for over two centuries.

What makes New Orleans deserve its title of "America's most interesting city"?

Is it its most even climate, with a summer temperature average of 78.3° F., and an average in October through March of 60.7° F.?

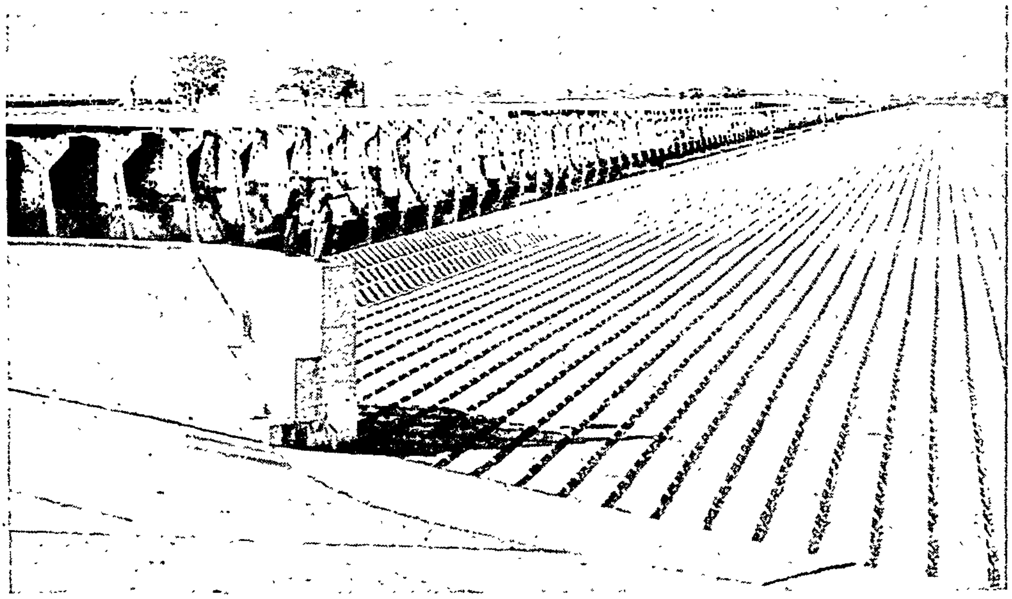
Is it its great port with a water frontage available for shipping of 133 miles, of which 50 are on the great Mississippi River and 11 on the Inner Harbor Navigation Canal?

Is it the great river itself which has a width of 2,200 feet at Canal street, in the center of the city, and a depth of 100 to 150 feet?

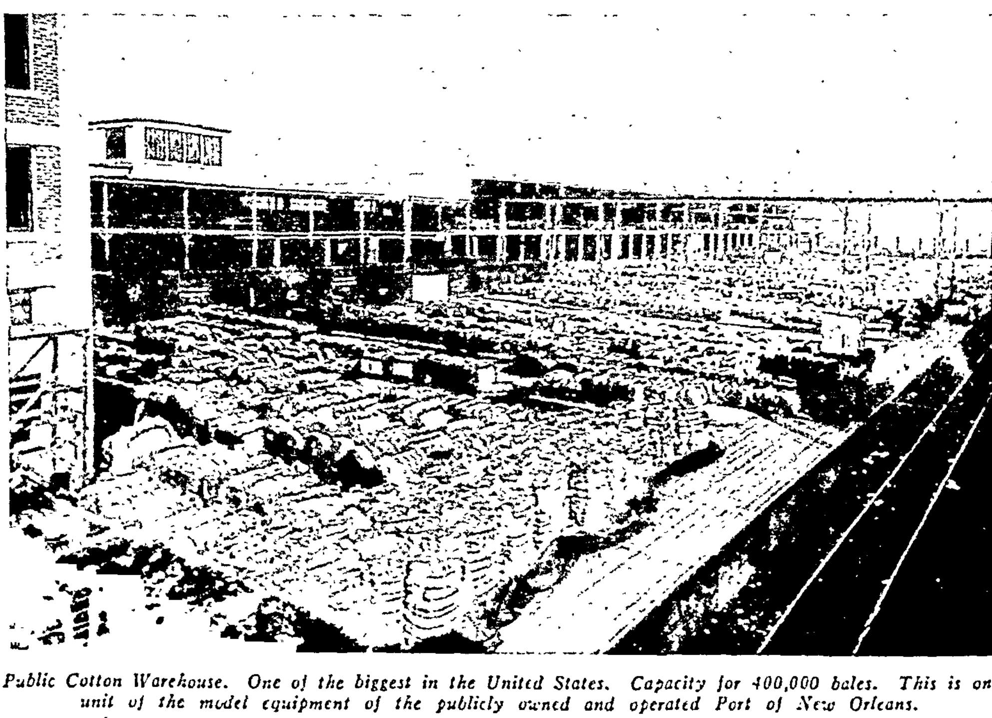
Is it the old French and Spanish section with its quaint architecture, its age, and its atmosphere of mystery and romance which steals over tourists and residents alike and charms them into willing and enthusiastic devotees of the "Vieux Carré"?

Is it perhaps the Mardi Gras which has been celebrated annually in New Orleans for over a century, and which traces its heritage from the Lupercalian feasts, well beyond the advent of the Christian era?

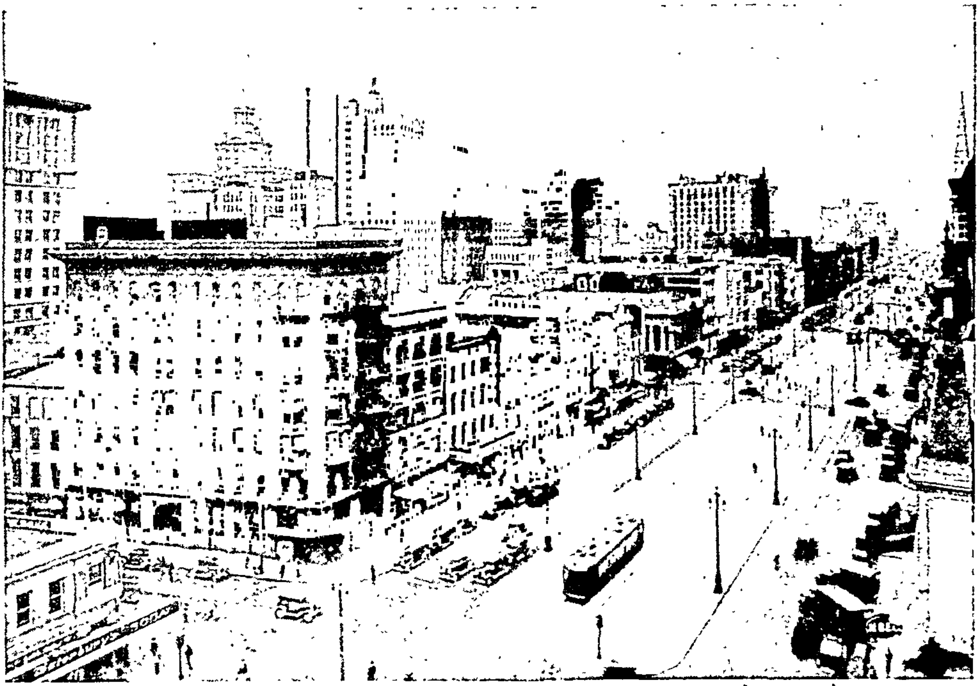
Is it perhaps the religious freedom and the remarkable tolerance to opinions and practices which characterize its people? Churches of all denominations and of varied architecture welcome the faithful. Among them are some of the most beautiful and best known in America. Of course,



The Bonnet Carre Spillway—Forever relieving New Orleans of the fear of Mississippi River floods, this great concrete by-pass—the only structure of its kind in the world—was completed in December, 1935, 30 miles above New Orleans, by the U. S. Army engineers. Its total cost was $13,000,000, including three bridges. With twice the flowage capacity of Niagara Falls, 500,000 second-feet, it will keep the water in the river at New Orleans from ever rising above the 20-foot flood level. The Spillway extends a mile and a half along the river and operates to spill the flood waters directly to sea level in Lake Pontchartrain nearby. The picture shows close-up the baffle-plates which break the force of the on-rushing waters.



Public Cotton Warehouse. One of the biggest in the United States. Capacity for 400,000 bales. This is one unit of the model equipment of the publicly owned and operated Port of New Orleans.



Canal Street, New Orleans. Five and one-half miles long, from Eads Plaza on the Mississippi River, to the Lake Front Park on Lake Pontchartrain. This street divides old and modern New Orleans.

the old St. Louis Cathedral, nearly a century and a half old, still stands, a great grey reminder of the past and pledge for the future.

Yes, it is all of these things, plus an intangible something, which is sometimes called personality but in modern parlance is so electrically and definitely described by the simple but significant word "it."

New Orleans was founded in 1718 by Bienville, the "Commandant General for the King" (Louis XIV of France), on a ridge of high land on the Mississippi, and about 115 miles from its mouth. This is the same site which is now occupied by the Vieux Carré.

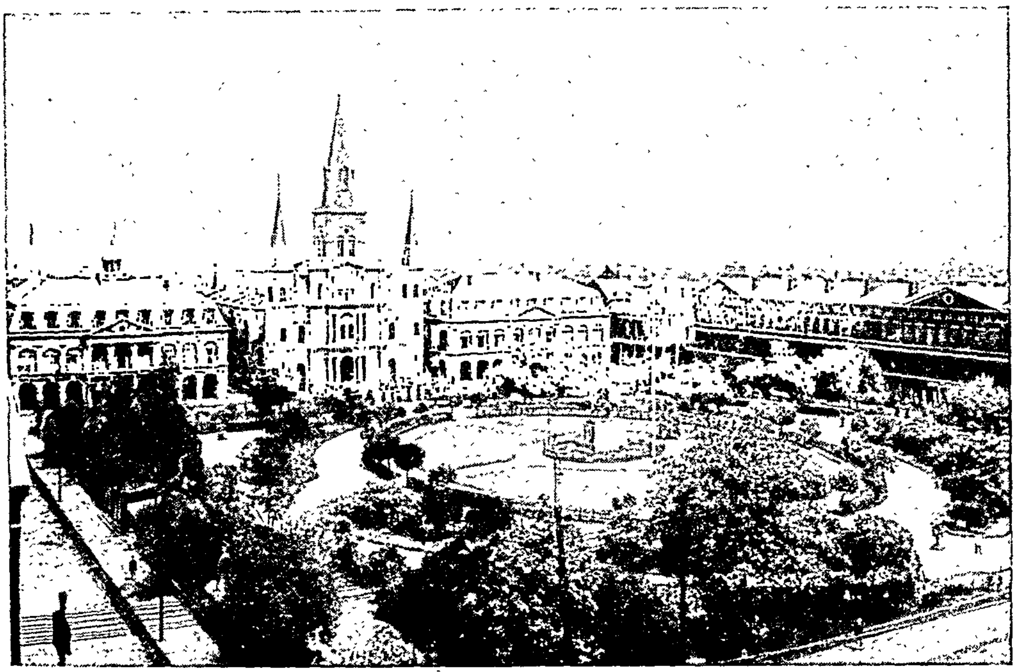
New Orleans was named after the Duke of Orleans, the regent of France and the patron of John Law and the Company of the West.

Throughout its colorful career of two and a quarter centuries, through French, Spanish, French, American, Confederate, and American domination, in succession, New Orleans has fought through periods of disease, floods, famines, war, and financial depression. In this city, in 1905, the last grand stand of civilization against the dread scourge of yellow fever was made and crowned with success.

As a direct sequel to yellow fever control, as a measure for prevention, the eradication of the Stegomyia (aedes) mosquito was imperatively necessary. The old above ground cypress cisterns, the principal breeding places of these mosquitoes, were destroyed and in their place a fine sparkling water, purified and distributed by a modern filtration plant with a capacity of over 120 million gallons a day, is furnished to the entire city.

This rapid sand filtration plant is one of the points of greatest interest to sanitarians and engineers and will be worth a visit.

To engineers, especially, and to all sanitarians in general, the sewerage

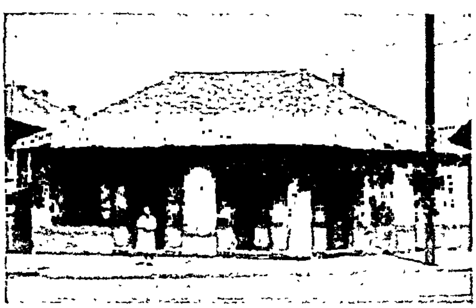


Heart of Old New Orleans. The Place d'Armes, where the Mississippi Valley development had its beginning in 1718, when New Orleans was laid out by Bienville.

Buildings left to right: Cabildo, erected in 1795 and the scene of the transfer of Louisiana from Spain to France, and from France to the United States in 1803; St. Louis Cathedral, built in 1794 on the site of Louisiana's first church; Presbytery, used originally by the Cathedral priests; Pontalba Apartment, one of the two rows of brick apartment style buildings, oldest in this country, erected by the Baroness Pontalba. In the foreground is Jackson Square where in 1769 the flag of Spain displaced that of France; the flag of France displaced that of Spain, and the American flag displaced that of France in 1803. In the center of the square is the Jackson Monument, designed by Clark Mills and unveiled in 1856.

The Cabildo and the Presbytery now house historic and natural history museums.

system will always be a source of wonder and admiration. When it is remembered that the topography of New Orleans is generally flat, and that some spots are below sea level, the difficulty from an engineering standpoint is immediately apparent. In spite of these conditions, for 36 years there has never been a serious interference with the smooth operation of the sewage disposal system.



One of the few remaining original adobe houses built of mud brick inset in cypress timbers with Spanish tile roof.

Malaria, once rampant, is now a rarity; only those cases coming from rural infection are available now for study. The elimination of malaria has been mostly due to the tremendous reclamation of land by drainage which has changed the surrounding territory from marsh lands to farm lands.

The points of particular attraction in New Orleans, to tourists as well as residents, who never tire of their charms, could easily keep one entertained for years, but even in a few days much can be seen and enjoyed.

Andrew Jackson's battlefield of Chalmette, with its monument to commemorate his victory over the heroes of Waterloo in 1815, lies just on the

edge of the city and can be reached in less than an hour.

The City Park, now one of the largest in the country, where, under the spreading oaks, many affairs of honor were settled in "ante bellum" days, is reached in 15 minutes from the hotels. Audubon Park, with its zoo, aquarium, golf links, and natural and cultivated beauty, is reached in 30 minutes from the center of the city.

Just across from the main entrance, on St. Charles Avenue, to Audubon Park are situated Tulane and Loyola Universities, beautiful in architectural arrangement and grounds, and noted centers of culture and education.

From the man-made fortifications at the end of Audubon Park, the hill-like levees, which hold the mighty Mississippi River in check, a wonderful view of this muddy torrent may be had, as it winds its tortuous way to the Gulf of Mexico.

From a tourist standpoint the old

The Spanish Arsenal, behind the Cabildo, was built by the Spanish Governor in 1770. It is architecturally one of the most distinctive buildings in the Old Quarter. It is now part of the Louisiana Historical Museum.

quarter, or the Vieux Carré, as it is affectionally called by all, is probably the greatest magnet for visitors. Here in an area of about 70 city squares are situated almost 60 spots of historic interest.

It is obviously impossible in this article to describe all the interesting spots in the Vieux Carré; indeed it would take a gifted word painter to convey even dimly the subtle charm, the hints of romance, and the reflection of deeds of valor and chivalry, that some of the age worn but still substantial monuments possess.

The Place d'Armes, now called Jackson Square, ruled over by the majestic St. Louis Cathedral, stands just back of the river banks in the center of the Vieux Carré. Flanking the Cathedral on either side are the Cabildo and the Presbytere, each of which is now used as a museum. In the Cabildo the transfer of Louisiana from France to the United States of America took place in 1803. On either side of Jackson Square the red brick Pontalba buildings, America's first apartment buildings, with their beautiful iron work railings, form a fitting framework for this beautiful section. A military air, accentuated by the famous equestrian statue of Jackson, which graces the central spot of the square, still permeates the atmosphere of this delightful and historic spot.

The old Ursulines Convent, now a parish presbytery, is just a few squares down from the Cathedral and is reputed to be the oldest building extant in the whole Mississippi Valley. It is over 200 years old.

The church of St. Anthony of Padua, known to old Creoles as the "dead church," because in yellow fever times all funerals were held there, built in 1826, is of particular interest. Just behind it lies the "old" St. Louis Cemetery, one of the best known and oldest in the United States. Here,

graves of settlers and inhabitants before the period of American domination, crumbling and time worn, still show inscriptions and constitute a never failing source of awe and interest to visitors.

The French Market, the Mint Building, the Louisiana Bank, the Bank of the United States, the Haunted House, Madame John's Legacy, and many other places are the meccas of never ending pilgrimages.

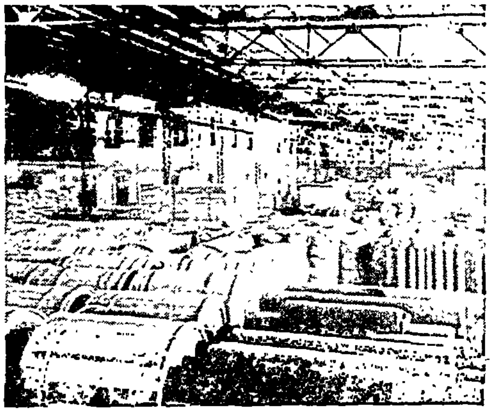
The hotels and "skyscrapers" of the modern city offer an imposing contrast to the Old Quarter. Over 3,500 first class hotel rooms are available, many air conditioned; in addition, thousands of other rooms are available.

Throughout the year, and throughout the city, beautiful flowers greet the pleased eye of the visitor. Flowers of all varieties from the humblest daisy to the proud orchid grow and thrive in New Orleans.

Above the city, a magnificent spillway, costing millions of dollars has been completed, and stands as a guarantee against any possibility of flood damage to New Orleans.

The new combined highway and railroad bridge is located just beyond the upper city lines. It cost $13,000,000 and completes a link in the Old Spanish Trail. It is the 29th bridge across the Mississippi and is the longest and finest of them all. It is toll free.

Crossing the bridge and following the old Spanish trail, within a couple of hours in an automobile or by bus, the Evangeline country, famous in poetry and prose, is comfortably reached. This is the land of the Atakapas, the land which inspired in Longfellow these lines:



Interior view of one section of a transit shed, showing the wide diversity of products handled at the Port of New Orleans

Beautiful is the land with its prairies and forest and fruit trees;
Under the feet a garden of flowers, and the blue of heavens
Bending above, and resting its dome on the walls of the forest.
They who dwell there have named it the "Eden of Louisiana."

Of course, there is not time to tell of the "year round" golfing, and boating, and fishing in the city limits of New Orleans; of the wonderful educational institutions and hospitals; of the social life—the balls, the Carnival, the racing season, the mid-winter sports carnival and many other inviting prospects for intended visitors.

New Orleans has a new commodious auditorium, one of the finest in the United States, ample for even the largest convention.

Above all, there is that indescribable "camaraderie" that natives seem born with, and new arrivals soon acquire, that makes for that atmosphere of friendliness and sociability which is an acknowledged quality of the "city care forgot," the Crescent City, New Orleans.

ASSOCIATION NEWS

AMERICAN PUBLIC HEALTH ASSOCIATION
SIXTY-FIFTH ANNUAL MEETING
NEW ORLEANS, LA.
OCTOBER 20–23, 1936

NEW ORLEANS EXECUTIVE COMMITTEE

Dr. J. M. Batchelor, Superintendent of Public Health, *General Chairman*
Dr. J. A. O'Hara, President, Louisiana State Board of Health
Dr. W. H. Seemann, State and City Bacteriologist. *Chairman, Publicity Committee*
Dr. Rigney D'Aunoy, Secretary, Medical Faculty, Louisiana State University, Medical Center. *Chairman, Scientific Exhibits Committee*
Dr. A. E. Fossier, Director, Public Health Education. *Chairman, Entertainment and Reception Committee*
J. H. O'Neill, State Sanitary Engineer. *Chairman, Meeting Rooms Committee*
Dr. W. H. Perkins, Director, Department of Preventive Medicine, Tulane Medical College.
Dr. C. C. Dauer, Assistant Professor of Preventive Medicine, Tulane Medical College. *Chairman, Registration and Information Committee*
C. L. Clay, State Analyst. *Chairman, Inspection Trips Committee*
Mrs. Charles F. Buck, Jr. *Chairman, Woman's Entertainment Committee*
Hon. A. Miles Pratt, Commissioner of Public Finances.
Dr. H. W. Kostmayer, President, Louisiana State Medical Society.
Dr. J. A. Henderson, Secretary-Treasurer and Chief Sanitary Officer, City Board of Health. *Chairman, Finance Committee. Treasurer*
Charles J. Ball, Assistant Superintendent of Public Health. *Secretary of Executive Committee*

WESTERN BRANCH A.P.H.A.

MEMBERS of the Association planning to attend the Seventh Annual Meeting of the Western Branch in Vancouver and Victoria, June 24 to 27, will be interested in the following travel information supplied by Dr. William P. Shepard, Secretary:

Vancouver may be reached by the Canadian National Railway through Winnipeg, Saskatoon, Wainright Buffalo Park, Edmonton, Jasper National Park, and the Canadian Rockies; by the Canadian Pacific by way of Winnipeg and Regina; or from Minneapolis to Moose Jaw, thence through Calgary, Banff, Lake Louise, and Rocky Mountain Park; also over the Great Northern by way of Minneapolis, Chicago, Havre, Glacier National Park, Spokane, and Everett. One may leave Minneapolis at 9:25 A.M. on a Saturday, arriving at Vancouver at 2:00 P.M. on Monday.

From Vancouver, the famous triangle tour may be taken, going by boat to Prince Rupert, just south of the Alaskan boundary, and back east by rail.

For those coming from the South, the Great Northern makes direct connections with the Southern Pacific at Portland and runs two trains a day from Seattle to Vancouver, one leaving at 8:05 A.M. and arriving at 2:00 P.M., another leaving at 5:00 P.M. and arriving at 10:15 P.M. The inter-coastal passenger steamship lines will probably be operating in June, and those who wish may enjoy an ocean voyage.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Albert L. Allen, M.D., University of North Carolina, Chapel Hill, N. C., Student—Health Officer Appointee

Franklin V. Boyd, M.D., Lake Providence, La., Director, East Carroll Parish Health Unit

George M. B. Bradshaw, M.D., Panama, N. Y., Health Officer

Irmel W. Brown, M.D., City Hall, Kalamazoo, Mich., Director of Public Health and Welfare

W. D. Burkhalter, M.D., Rockford, Ala., Coosa County Health Officer

Jose Chaves, M.D., Health Dept., San Juan, P. R., Director, Public Health Units

Isadore Cohn, M.D., 771 West End Ave., New York, N. Y., District Health Officer, New York City Dept. of Health

George R. Collins, M.D., East Main, Avon, N. Y., Health Officer

Edwin L. Crosby, M.D., 3000 Reisterstown Rd., Baltimore, Md. (temporary leave of absence), Epidemiologist-in-training, New York State Dept. of Health

Patrick H. Fleming, M.D., 311 S. Main St., St. Martinsville, La., Director, St. Martin Parish Health Unit

Frank K. Harder, M.D., City Hall, Cincinnati, O., Assistant Commissioner of Health

Walter N. Kirkman, State Dept. of Health, Baltimore, Md., Chief, Division of Personnel and Accounts

Wilbur A. McPhaul, M.D., Box 210, Jacksonville, Fla., State Health Officer

Erastus L. Miller, M.D., P. O. Box 327, Jena, La., Director, La Salle Parish Health Unit

Raymond J. Pieri, M.D., Medical Arts Bldg., Syracuse, N. Y., Health Officer, Geddes, N. Y.

Colonel Henry C. Pillsbury, M.D., Army Medical Center, Washington, D. C., Medical Corps, U. S. Army

Edwin W. Sigler, M.D., Cadiz, Ky., Director, Trigg County Health Dept.

John A. Skladowsky, M.D., City Health Dept., Baltimore, Md., Medical Health Officer

Morton Torrance, M.D., Maple St., Harpursville, N. Y., Health Officer, Colesville, N. Y.

James A. Whitaker, M.D., Rocky Mount, N. C., Health Officer

Laboratory Section

Harold A. Ansley, M.B., D.P.H., General Hospital, Hamilton, Ont., Canada, Assistant in Public Health and Pathology

Isadore R. Asen, B.S., 33 Lincoln Park, Newark, N. J., Director, Clinical Laboratory, Newark, N. J.

James Bell, M.D., Provincial Laboratory, Fort William, Ont., Canada, Director, Fort William Branch Laboratory, Ontario Dept. of Health

Silas H. Champlin, Heekin Can Co., Norwood, O., Head, Food Research

Natale Colosi, Ph.D., 308 E. 116 St., New York, N. Y., Instructor in Bacteriology, New York University, College of Medicine; Director, Colosi Pathological Laboratories

Izetta Fine, B.S., 816 Oregon Bldg., Portland, Ore., Laboratory Technician, Oregon State Hygienic Laboratory

Carlos M. Garcia, M.D., Calle J. #2, Vedado, Habana, Cuba, Special Sanitary Inspector, Havana Milk Supply

Michael Gerundo, M.D., 209 S. Main, Fort Scott, Kans., Pathologist, Mainstreet Hospital

John A. Killian, Ph.D., 50 E. 41 St., New York, N. Y., Research—biochemistry and nutrition

Moses Kopel, M.D., 1454 Grand Concourse, Bronx, N. Y., Pathologist, Gouverneur Hospital

John L. Lattimore, M.D., 618 Mills Bldg., Topeka, Kans., Director, Lattimore Laboratories

Arthur E. Potts, University of Saskatchewan, Saskatoon, Sask., Canada, Professor of Dairying

Allan C. Rankin, D.P.H., University of Alberta, Edmonton, Alta., Canada, Professor of Bacteriology and Hygiene

Winnifred C. Riddle, Faculty of Dentistry, University of Toronto, Toronto, Ont., Canada, Laboratory Assistant in Biology, Histology, Bacteriology and Pathology

Henry H. Smach, 2530 S. Ridgeland Ave., Berwyn, Ill., Chemist and Bacteriologist, Health Dept.

Manuel S. Tarpinian, 608 Kresge Bldg., Detroit, Mich., Physicians' Service Laboratory

Solomon Weintraub, M.D., 240 E. 79 St., New York, N. Y., Pathologist, Harlem Hospital

Cleveland J. White, M.D., 122 S. Michigan Ave., Chicago, Ill., Associate in Dermatology, Northwestern University Medical School

Alexander S. Wiener, M.D., 520 Crown St.,

Brooklyn, N. Y., Director of Clinical Laboratory

Giuseppe S. Zuccala, 16 Beacon Hills Rd., Port Washington, L. I., N. Y., Director, North Shore Clinical Laboratory

Vital Statistics Section

Marie Di Mario, 2704 University Ave., New York, N. Y., Assistant Supervisor of District Health Records, New York City Health Dept.

Pressley A. Kibbe, M.D., 2000 Tulane Ave., New Orleans, La., State Registrar of Vital Statistics

Manuel A. Perez, 53 Loiza St., Santurce, P. R., Chief Statistician, Health Division, Puerto Rico Reconstruction Administration

Alexander K. Powell, 209 S. Campbell St., El Paso, Tex., Registrar and Statistician, El Paso City County Health Unit

Public Health Engineering Section

John H. Barry, M.D., 2135-45 Rd., Long Island City, N. Y., Assistant Sanitary Superintendent, New York City Dept. of Health

Richard H. Bearden, 50 Morningside, New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Carl J. Bernhardt, 145 Anderson Place, Buffalo, N. Y., Assistant Sanitary Engineer, State Dept. of Health

Angelo Boffi, 10130-126 St., Richmond Hill, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

James F. Brennan, 1372 Shakespeare Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

William C. Buntin, M.D., Dept. of Health, Staten Island, N. Y., Assistant Sanitary Superintendent

Peter J. Craig, 141-24-183 St., Springfield, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

William A. Cummings, 67 Green St., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

John J. Dooley, 409 E. 88 St., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Michael F. Fitzgerald, 434 E. 67 St., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Matthew F. Greene, 9010-86 Rd., Woodhaven, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

Joseph Hardardt, 4397 Martha Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

John Heatley, 191-11 Woodhull Ave., Hollis, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

John Hertel, 1990 Ellis Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

Eugene Howard, 102 E. 238 St., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

William S. Irving, 3543 Willett Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

Joseph M. Jenks, 89-18 146 St., Jamaica, L. I., Sanitary Inspector, New York City Dept. of Health

Peter Johnson, 2228 Amsterdam Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

John Kelly, 1501 Undercliff Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

William J. Kirchner, State St., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

Francis J. Laverty, R.F.D. 164, Briarcliff Manor, N. Y., Assistant Sanitary Engineer, New York City Dept. of Health

Edward H. Leiber, 2113 Quimby Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

William J. Mansfield, 95-05-35 St., Jackson Heights, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

Nathaniel Milbauer, 1634 Popham Ave., Bronx, N. Y., Sanitary Inspector, New York City Dept. of Health

Fanny Z. Mitchell, R.N., 475 King Ave., City Island, N. Y., Sanitary Inspector, New York City Dept. of Health

Meron M. Mogil, 220 Boulevard, New Haven, Conn., Sewage Work, Nustone Products Corp.

James F. Morrison, M.D., 1221 Bergen St., Brooklyn, N. Y., Assistant Sanitary Superintendent, Brooklyn Division, New York City Dept. of Health

Hugh A. Newman, 530 W. 182 St., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Leroy H. Null, 138-56-223 St., Laurelton, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

William J. Plunkett, 72 Seaman Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Nicholas A. Post, 59-27-69 Lane, Maspeth, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

Edwin Rasenberger, 105-05-188 St., Hollis, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

Samuel S. Reisman, 3723–18 Ave., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

Ellsworth Roberts, 1864 Seventh Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Arthur Rosenberg, 245–96 St., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

John J. Ryan, Jr., 848 Ninth Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

William Sauer, 8972 Hollis Court Blvd., Queens Village, L. I., N. Y., Sanitary Inspector, New York City Dept. of Health

Conrad C. Sofleiss, 9439–120 St., Richmond Hill, N. Y., Sanitary Inspector, New York City Dept. of Health

Michael Styler, 235 Fort Washington Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Fred Wasserman, 126 Manet Rd., Newton, Mass., Student, Public Health Engineering, Massachusetts Institute of Technology

William T. Winder, 2555 Mickle Ave., New York, N. Y., Sanitary Inspector, New York City Dept. of Health

Edward Wyckoff, 110 Bay 10 St., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

Industrial Hygiene Section

Clarence Muehlberger, Ph.D., 222 E. Superior St., Chicago, Ill., Toxicologist, Cook County

Richard T. Page, State Dept. of Health, Charleston, W. Va., Public Health Engineer, Bureau of Industrial Hygiene

Frederick H. Shillito, M.D., 630 W. 168 St., New York, N. Y., Instructor in Medicine in Industrial Hygiene, Columbia University

Food and Nutrition Section

Eva Denzer, 157–08–92 St., Ozone Park, L. I., N. Y., Inspector of Foods, New York City Dept. of Health

Lemoyne C. Kelly, M.D., 133 E. 58 St., New York, N. Y., Assistant Physician, Bureau of Tuberculosis, New York City Dept. of Health

Child Hygiene Section

Sarah S. Deitrick, M.D., C.P.H., U. S. Dept. of Labor, Washington, D. C., Field Consultant, Children's Bureau

Adelaide R. Ross, 720 Mass Ave., Cambridge, Mass., Director of Health, Malden School Dept.

Public Health Education Section

Lindsley F. Cocheu, 205 E. 69 St., New York, N. Y., Head of Dept. of Bacteriology, Clinical Pathology, and Public Health, New York Homeopathic Medical College and Flower Hospital

A. Arthur Feller, M.D., 465 Bedford Ave., Brooklyn, N. Y., Physician in charge of Clinic, New York City Dept. of Health

Elizabeth M. Finigan, 240 S. Goodman St., Rochester, N. Y., Lecturer and Special Investigator for Children's Homes, State Dept. of Health

Dr. Victor Grossi, Bellavista 478, Valparaiso, Chile, S. A., Head of Sanitary Service of Aconqaqui

Carroll J. Roberts, M.D., 2732 Main St., Buffalo, N. Y., Clinical Director, Buffalo City Hospital

Arthur J. Strawson, 1108 Little Bldg., Boston, Mass., Executive Secretary, Massachusetts Tuberculosis League

Public Health Nursing Section

Dorothy Deming, R.N., C.P.H., 50 W. 50 St., New York, N. Y., General Director, National Organization for Public Health Nursing

Mary Lucier, 528 W. 111 St., New York, N. Y., Henry Street Nurse

Margaret E. Newman, Bewley Bldg., Lockport, N. Y., Executive Secretary, Niagara County Health Assn.

Julia B. Paluszak, St. Mary's Hospital, Passaic, N. J., Public Health Nurse

Erna M. Sohmer, R.N., 62 Tallman Ave., Nyack, N. Y., School Nurse

Epidemiology Section

John S. Douglas, M.B., D.P.H., Quarantine Station, Father Point, P. Que., Canada, Quarantine Officer, Dept. of Pensions and National Health

Unaffiliated

Howard M. Freas, M.D., 179 Dwight St., New Haven, Conn., Student

Charles E. Gill, M.D., Westfield State Sanatorium, Westfield, Mass., Senior Physician

Worth L. Howard, 525 W. Market St., Akron, O., Administrator, City Hospital of Akron

Gertrud M. C. Kroeger, 4901 Ellis Ave., Chicago, Ill., Research Assistant, Hospital Administration and Medical Economics, Julius Rosenwald Fund

Charles S. Nelson, 79 E. State St., Columbus, O., Executive Secretary, Ohio State Medical Assn.

MEETING OF THE EXECUTIVE BOARD OF THE ASSOCIATION

A MEETING of the Executive Board was held in Washington, D. C., on April 16 at the conclusion of the Conference of State and Territorial Health Officers with the Surgeon General. All members of the Board were present. Important actions were taken by the Board, among which the following may be mentioned.

Professor C.-E. A. Winslow, who since the organization of the Committee on Administrative Practice in 1920 has been Chairman, presented his resignation which was regretfully accepted by the Board. A resolution in appreciation of Professor Winslow's service to the Association is published herewith.

Eugene L. Bishop, M.D., F.A.P.H.A., and past President of the Association was made Chairman of the Committee on Administrative Practice for the duration of his present term on the committee.

The Board also received with regret the resignation of C. C. Young, D.P.H., as Chairman of the Committee on Meetings and Publications. Dr. Young has been chairman of this committee since 1929. The Board's resolution is carried on the next page.

The Board appointed the Executive Secretary as Chairman of the Committee on Meetings and Publications.

The Board adopted three resolutions which grew out of the memorandum on Authoritative Standards and Association Policy presented by Wade H. Frost, M.D., at the meeting of the Executive Board held December 19, 1935, and published in the April *Journal.*

1. It was voted that committees generally, and especially those dealing with proposed standards, be instructed to record the dissent of individual members to statements and recommendations approved by a majority and, where this affords inadequate expression, to file a minority report.

2. Voted that, with regard to proposals which pass through the Committee on Research and Standards, the Board directs that this committee as a whole or a sub-committee which takes no part in the initiation of any standards review each proposal critically from the standpoint of Association policy and, where there seems to be any probability that legitimate questions may be raised concerning the justification of the proposed standardization, arrange to have the question presented for discussion.

3. The Board directs that, with respect to reports originating in committees of the whole Association, those which propose standard procedures to be promulgated in the name of the Association be required to stand before the Association merely as proposals under consideration for a period sufficient to allow ample time for the preparation of written discussions and their publication before they are presented for action by the governing body.

The Executive Board extended a cordial invitation to the National Organization for Public Health Nursing to consider meeting with the American Public Health Association in 1937.

Robert S. Breed, Ph.D., was appointed, on recommendation of the Laboratory Section, as Association representative to the International Microbiology Congress in London beginning July 25. W. Frank Walker, Dr.P.H., was appointed Association representative to the Advisory Committee of the General Federation of Women's Clubs. The appointment of A. J. Lanza, M.D., of the Industrial Hygiene Section, as Association representative to the Conference on Silicosis and Similar Dust Diseases called by the Secretary of Labor was confirmed.

The Board approved in principle the continuation of the City Health Conservation Contest for 1936 as recommended by the Contest Committee and the Committee on Administrative Practice.

The Board directed that the Committee on Meetings and Publications

review the present status of the schedule as approved by the Governing Council for future meeting places of the Association with a view to a possible revision of this schedule.

Fiorello H. La Guardia, Mayor of the City of New York, petitioned the Board to consider the establishment of a permanent museum of hygiene exhibit following the world's fair planned for New York City. This matter was referred to the Committee on the American Museum of Hygiene.

In considering the Association budget the Board was advised of the fact that substantial additional funds had become available since the beginning of the year for the promotion of certain studies by the Sub-committee on the Evaluation of Administrative Practices and the Sub-committee on Revision of the Rural Appraisal Form. A general recasting of the Association budget for the year was necessary on this account.

The Board was advised that the financial status of the Association was reasonably satisfactory and that it was particularly encouraging to note the increase in membership as a result of efforts put forward by the Committee on Fellowship and Membership this year.

Resolutions Passed by the Executive Board at a Meeting in Washington, D. C., April 6, 1936

C.-E. A. WINSLOW

WHEREAS, Professor C.-E. A. Winslow has served as Chairman of the Committee on Administrative Practice for 15 years, and

WHEREAS, during that period which represents the committee's lifetime he has been its guide and leader, and

WHEREAS, his incalculable contribution of knowledge, enthusiasm and wisdom expended without stint throughout these years has identified the name of Winslow with public health administration for all time, therefore, be it

RESOLVED, that the Executive Board of the American Public Health Association, accepting regretfully his resignation as Chairman of the Committee, record its warm appreciation of his work and its esteem of the man; be it further

RESOLVED, that this resolution be spread upon the minutes, circulated to Professor Winslow's friends and associates and published to the membership of the American Public Health Association in the *American Journal of Public Health.*

C. C. YOUNG

The Executive Board has received with regret the resignation of Dr. C. C. Young as Chairman of the Committee on Meetings and Publications.

In accepting this resignation the Board records with appreciation the constructive services rendered to the Association by the committee under Dr. Young's leadership. During these years the Annual Meetings have been made more serviceable to the members and a new quality of financial independence has been achieved. The *Journal* has been expanded and notably improved, and similar progress has been made among all Association publications.

It is the opinion of the Board that these responsibilities could not have been better handled during this period of decentralized administration than by Dr. Young, to whom the Association will long remain deeply indebted.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instructors:

University of California, Los Angeles, Calif.—June 27–August 7
Colorado State College, Fort Collins, Colo.—July 11–August 21
University of Minnesota, Minneapolis, Minn.—June 15–July 25
Peabody College, Nashville, Tenn.—June 8–July 15
Pennsylvania State College, State College, Pa.—June 29–August 7
Syracuse University, Syracuse, N. Y.—July 6–August 15

University of California, Berkeley, Calif.

June 29–August 7

General Bacteriology
Child Development
Public Welfare Administration
Supervision in Public Health Nursing
Principles and Practice of Public Health Nursing
Introduction to Educational Psychology
Control of Poverty
Elements of Economics
General Psychology
Elementary Epidemiology *
Elementary Public Health *

* These two courses are offered in the Intersession, May 18–June 26

The Catholic University of America, Washington, D. C.

June 26–August 8

Child Study
Nursing Education
Public Health Nursing
Social Work
Sociology

Columbia University

DeLamar Institute of Public Health, College of Physicians and Surgeons, New York, N. Y.

June 8–26

School Health Supervision—Medical Inspection, Mental Hygiene, and Physical Education

(These courses will not be given unless ten candidates have signified their intention to register before May 1st.)

Teachers College, Columbia University, New York, N. Y.

July 7–August 14

Organization of Health Education in Public Schools
Child Hygiene
Health Education
Health and Physical Education
Health Care of Children
Home and Community Hygiene
Nutrition and Health
Personal and General Hygiene
Public Health Nursing
Public Health Administration
Safety Education Materials and Methods
School Nursing
Teaching Lip-Reading
Sight Saving Classes
Social Hygiene
Psychology of Exceptional (Subnormal) Children
Speech Correction
Speech Correction Clinic

When communicating with these summer schools, refer to the above announcement in the *Journal*

Cornell University, Ithaca, N. Y.

July 6–August 14

Physical Education:
- Gymnastics (Women)
- Leadership in Community Recreation Program

Health Education:
- Mental Hygiene of Childhood
- School Health Problems

University of Denver, Denver, Colo.

June 15–August 21

Social Sciences
Speech Conference

Duke University, Durham, N. C.

June 11–July 22

Materials and Methods in Health Education
Personal and School Hygiene

The University of Hawaii, Honolulu, Hawaii

June 29–August 7

Conservation of Sight
Principles of Health Education in School Hygiene

University of Illinois, Urbana, Ill.

June 15–August 8

Physical Education for Men:
- Physical Education
- Adapted Activities
- Program in Extracurricular Sports
- Curriculum in Physical Education

Physical Education for Women:
- Physical Education
- Community Recreation
- Team Sports for High School Girls
- Physical Education Program for the High School
- Methods of Teaching Health
- Principles of Body Movement

State University of Iowa, Iowa City, Iowa

June 8–August 20

Hygiene
Nursing
Nutrition
Physical Education

Massachusetts Institute of Technology, Cambridge, Mass.

June 16–July 28

THOMAS PARRAN, JR. M.D.

THOMAS PARRAN, JR., M.D., F.A.P.H.A., took the oath of office as Surgeon General of the U. S. Public Health Service on April 6, succeeding Hugh S. Cumming, M.D., F.A.P.H.A. Dr. Parran was nominated by President Roosevelt in March, when the matter was referred to the Senate for confirmation.

DR. GODFREY NEW YORK STATE COMMISSIONER OF HEALTH

EDWARD S. GODFREY, JR., M.D., F.A.P.H.A., Assistant Commissioner of Health of New York State, was nominated on April 6 by Governor Herbert H. Lehman to succeed Thomas Parran, Jr., M.D., as State Commissioner of Health.

Dr. Godfrey was appointed a sanitary supervisor of the department in July, 1917, by Hermann M. Biggs, M.D., who was then Commissioner of Health, and he subsequently served as epidemiologist, and later as director of the division of communicable diseases, until 1931, when he was appointed director of local health administration, and 3 years later was made Assistant Commissioner of Health in charge of this bureau.

DR. FRANCIS X. MAHONEY

FRANCIS XAVIER MAHONEY, M.D., was born in Boston, Mass., July 6, 1872. He died in Boston, January 14, 1936.

After receiving his degree of M.D. at Harvard Medical School, in 1902, he continued his medical studies a year in Vienna. In 1905 he took a postgraduate course at Harvard University.

He was appointed a member of the Boston Board of Health in 1910. When the Board of Health was superseded by a Health Commissioner in 1915, Dr. Mahoney became the first Commissioner, which position he held until his death, with the exception of the period from August 1, 1918, to February 23, 1922.

Dr. Mahoney was sympathetic with efforts to bring public health officials in closer touch with the public. He established the first Health Unit in Boston in 1916, primarily to promote public education in matters relating to

health and also to secure more effective coördination between health officials and agencies designed to promote public welfare. He obtained in 1923 the approval of the Trustees of the Robert E. White Fund to utilize its income to extend further this idea, and he thus led to the creation of Boston's present chain of Health Units.

Boston's water supply was in the hands of a State Commission, but Dr. Mahoney succeeded in prohibiting the use of lead in all new water main connections in Boston. He won a long fight against commercial interests almost single-handed and drove out of Boston the traffic in old eggs for food purposes.

He was one of the first to recognize officially that changes in milk which progressively affect its nutritive properties, begin promptly, and insisted that the deterioration be delayed by keeping it at a low temperature and by lessening opportunities for bacterial contamination. His dairy inspectors were chased off farms with pitch forks and thrown off milk trains, but eventually they were considered helpful both by producers and distributors.

He contended from the first that "the only safe milk is pasteurized milk." He insisted that "certified milk" should be pasteurized. His views came to be generally recognized. From less than 30 per cent in 1910, he finally saw over 98 per cent of the milk sold in Boston pasteurized. Then came his fight in behalf of the milk consumers of Boston to preserve their right to prescribe the standard of milk which might be marketed in Boston, and to prevent such authority from being turned over for political reasons by the Legislature to political appointees without local responsibility.

Dr. Mahoney was a member of the American Medical Association, the International Health Officers' Association, the Massachusetts Medical Society, the Massachusetts Association of Boards of Health, and of the Boston Tuberculosis Association, Boston Council of Social Agencies, and Honorary President of the Boston Health League. He became a member of the American Public Health Association in 1912 and was elected to Fellowship in 1922.

DR. FLEMING AT MC GILL

DR. A. Grant Fleming, F.A.P.H.A., Director of the Department of Public Health and Preventive Medicine of McGill University, Montreal, Quebec, has been appointed Dean of the Faculty of Medicine at McGill for a 3 year period beginning September 1, 1936.

With Dr. Fleming's accession to the deanship, the Dominion of Canada will have public health men as deans of the two largest medical schools, Dr. J. G. FitzGerald, F.A.P.H.A., being Dean of the Faculty of Medicine at the University of Toronto.

DR. GARLICK

JOSEPH B. Garlick, M.D., well known physician of Schenectady, died recently in Florida following a heart attack.

Dr. Garlick had been Health Officer of the city of Schenectady on a part-time basis from 1916 to 1918. In August, 1934, he was appointed acting Commissioner of Health to fill the unexpired term of the late Dr. MacDonald, and was reappointed for a 4 year term in 1935. During his recent tenure he had taken active part in the promotion of venereal disease clinic facilities and of the pneumonia control program.

He was a member of the Pan-American Medical Society, American Medical Association, the New York State Medical Society, and the Schenectady County Medical Society of which he was a past president; and has been a member of the A.P.H.A. since 1935.

DR. ROGER PERKINS

DR. Roger Perkins, 62 years old, pathologist and bacteriologist and Professor Emeritus of Western Reserve University, died March 28 after a long illness.

He had made his home at South Kingstown, R. I., since moving in 1930 from Cleveland, O., where he had served on the faculty of Western Reserve Medical School since 1901. He had served as city bacteriologist in 1906, 1907, 1913, and 1914; and from 1914 until 1923 he was chief of the Bureau of Labor, Division of Health. He was named a trustee of the Brush Foundation in Cleveland in 1931.

During the World War Dr. Perkins served as a member of the American Red Cross Commission to Rumania, as Medical Associate to the Scientific Attache in the American Embassy in Paris, and, in 1919, as Director of the Sanitation Division of the American Red Cross Commission to the Balkan States.

He has been a member of the A.P.H.A. since 1902, a Fellow since 1922, and a Life Member since 1929.

DR. PARK

THE *Canadian Public Health Journal* for March, 1936, has an article, "The First Production of Diphtheria Antitoxin in the United States," by William H. Park, M.D., whose work in diphtheria is so well known. It is said that this record has not been previously published.

It also contains an editorial with a well deserved tribute to Dr. Park.

QUALIFICATIONS FOR NURSES

THE Minimum Qualifications for Those Appointed to Positions in Public Health Nursing have been revised by the Committee on Education of the National Organization for Public Health Nursing and the Committee on Professional Education for the next 5 year period. These revised qualifications were approved by the Governing Council of the A.P.H.A., and are now available in reprint form at the Association office.

MALARIA CONGRESS IN SPAIN

THE Third International Congress on Malaria will be held in Madrid, October 12–18, 1936, "under the high patronage of His Excellency the President of the Spanish Republic."

Dr. Gustavo Pittaluga, of Madrid, Honorary Fellow of the A.P.H.A., is *President.*

All correspondence is to be addressed to Dr. Manuel G. Ferradas, Secretary, Instituto Nacional de Sanidad, Calle de Recoletos, 19, hotel, Madrid.

ALABAMA HAS NEW HEALTH UNIT

RECENTLY a full-time health unit was set up in Coffee County, Ala., bringing the total of full-time health departments in the state to 57, leaving 10 counties without organized health service.

Dr. Henry T. Donovan, of Elba, Ala., is the Health Officer.

MISSISSIPPI HAS NEW HEALTH UNIT

THE Health Department of Marshall County, Miss., has recently been organized on a full-time basis. Dr. Vernon B. Harrison, formerly Health Officer of Coahoma County, has been appointed Health Officer of the new unit.

SILICOSIS CONFERENCE IN WASHINGTON

A CONFERENCE was called by Miss Frances Perkins, Secretary of Labor, in Washington, on April 14, on Silicosis.

The Industrial Hygiene Section of the A.P.H.A. and the Association at large were represented at the conference by A. J. Lanza, M.D., F.A.P.H.A., and Henry H. Kessler, M.D., Fellow A.P.H.A., respectively. Twelve Fel-

lows of the Section were in attendance and these names were well represented among the major committee appointments.

FLORIDA HEALTH UNIT

A PUBLIC health unit has been established in Broward County, Fla., with Dr. Paul G. Shell, formerly of Marianna, in charge. The new unit will be maintained by Lauderdale, Hollywood, and Broward Counties, their combined contribution of $5,000 to be matched by a similar amount from the state and federal governments.

Headquarters will be in Hollywood, Fla.

DEATH

MABEL LEILANI SMYTH, member A.P.H.A., of Kalihi, Hawaii, died March 31. She was President of the City County Nurses' Association, and was for the past 8 years Director of Public Health Nursing in the Board of Health of the Territory of Hawaii, and prior to that was head nurse at Palama Settlement, having been the first director of nurses at that institution.

PERSONALS

JOHN E. WORDEN, M.D., has been appointed State Health Officer of Nevada, with headquarters at Carson City, succeeding Edward E. Hamer, M.D., F.A.P.H.A.

DR. HARRY F. WILSON, member A.P.H.A., Health Officer of Dillon and Marion Counties, S. C., has been appointed Director of the Industrial Hygiene Division of the State Board of Health of South Carolina.

DR. MAURICE C. HALL, who was chief of the Zoölogical Division of the Bureau of Animal Industry, of the Department of Agriculture, Washington, D. C., has been transferred to the National Institute of Health, where he will be chief of the Division of Zoölogy.

CHARLES G. POWER, of Quebec, a lawyer and a member of Parliament at various times since 1917, has been appointed Minister of Pensions and National Health for Canada.

WILLIAM D. BURKHALTER, M.D., member A.P.H.A., of Nashville, Tenn., was recently appointed Health Officer for the newly organized Health Department of Coosa County, Ala., with headquarters at Rockford.

LORENZO L. PARKS, M.D., member A.P.H.A., of Auburn, Ala., has been appointed Health Officer of Edgecombe County, N. C.

ALONZO E. HARDISON, JR., M.D., member A.P.H.A., of Maryville, Tenn., has been appointed Director of the Blount County Health Department to succeed Dr. Owen F. Agee, resigned.

DR. DAVID T. BUNDY, of Tyler, Tex., was recently named Health Officer of Smith County, succeeding the late Dr. Benjamin T. Bryant.

DR. ROBERT E. HARPER, of Moulton, Ala., has been named Health Officer of Colbert County, succeeding Dr. George W. Warwick, of Birmingham.

DR. SAMUEL B. MCPHEETERS, of Charlotte, N. C., has been appointed Health Officer of Wayne County.

DR. MAURICE L. PETER, of Blackwell, Okla., has been appointed Health Officer of Kay County, to succeed Dr. Luther H. Becker.

DR. MARSHALL D. CARNELL, of Okmulgee, Okla., has been appointed Health Officer of Okmulgee County to succeed the late Dr. John J. C. Rembert.

DR. JOHN L. BURKHARDT, for many years City Health Officer of Big Rapids, Mich., has been appointed Postmaster.

DR. JOHN W. DARROUGH, of Everett, Wash., was recently appointed Health Officer of Everett.

DR. JOHN W. STEVENSON, of Hoquiam, has been appointed Health Officer of Grays Harbor, Wash.

CONFERENCES AND DATES

May 1, May Day–Child Health Day.

May, Food Industries Exposition, Oakland, Calif.

Positions Wanted

HEALTH OFFICERS

Physician, M.S.P.H. Columbia University, with experience in district health administration, desires position as health officer or in other public health administrative capacity. A-227

Man, licensed sanitary inspector and health officer in New Jersey; experience as health officer and bacteriologist, and in conducting health surveys, organizing county and state tuberculosis associations; desires administrative position in public health. A-229

LABORATORY

Man, M.Sc. University of North Dakota; experience includes several years as city and state bacteriologist and chemist; desires position in public health laboratory. L-230

Young woman, A.B. Wellesley, C.P.H. Massachusetts Institute of Technology; 1 year's research experience at Harvard School of Public Health and 1 year as technician in city health department; desires position in laboratory—preferably research. L-231

Young man, graduate Louisiana State University; 3 years in Army Medical School as a medical laboratory technician; desires position as laboratory technician in New Jersey or New York. L-232

Young woman, graduate College of Agriculture, University of Maryland; temporary employment during two summers as assistant bacteriologist in food laboratory; desires position in dairy or sanitary bacteriology. L-233

Man, M.D. University of Kentucky; several years' experience as bacteriologist in city health department and as instructor in bacteriology in a medical school; desires position as bacteriologist. L-234

Young man, M.S. University of Maryland; 1 year's experience as technician, U. S. Public Health Service; desires position as laboratory technician or junior bacteriologist. L-235

MISCELLANEOUS

Physician, M.D. Harvard; several years' experience as instructor of industrial medicine and as consultant in occupational diseases; desires position in industrial hygiene field. A-228

Epidemiologist and State Health Officer with seven years' office and field experience, available for 6 to 8 months from June 1st for special detail anywhere. Has also had extended experience in tropical medicine, parasitology, hygiene and sanitation. Is now engaged in teaching and research in Class A medical school. Graduate of Northwestern University Medical School, Liverpool School of Tropical Medicine and Hygiene; School of Hygiene and Public Health, Johns Hopkins University. 170

Man, Sc.D. Johns Hopkins School of Hygiene and Public Health; experience in teaching and research in biometry, vital statistics, physical anthropology and statistical methods, including supervision of computations and the construction of codes for punch-card tabulating systems; also editorial experience; desires position in field of vital statistics. A-236

Woman, M.S. University of Michigan; 1 year graduate study towards Ph.D., New York University; 10 years' experience including supervising physical education and instruction in health education; desires position in health education field. M-236

> Persons with medical and post-graduate education who are seeking employment are invited to communicate with the Executive Secretary in regard to several available opportunities.

Position Available

NOTICE OF EXAMINATION

The New York State Department of Civil Service will hold an examination for the position of epidemiologist in the New York State Department of Health probably some time during May, the date to be announced later. The specifications for this examination are as follows:

EPIDEMIOLOGIST, Department of Health. Appointment expected at $4,250. Duties: To make diagnoses of communicable disease cases; to investigate outbreaks and the endemic occurrence of communicable diseases; to make special studies for the purpose of improving methods for controlling these diseases; to instruct the personnel of local health departments in epidemiological procedure, and to stimulate improvement of local control measures. Candidates must be graduates of medical schools registered by the New York State Department of Education and must be registered or eligible for license and registration to practice medicine in New York State. In addition they must have completed a post-graduate course in public health of at least one scholastic year of residence, and must have had not less than one year of satisfactory experience in communicable disease control work in a city, county or state department of health or in similar organization. Subjects of examination: Written examination on the knowledge and skill involved in performing the duties, relative weight 4; training, experience and general qualifications, relative weight 6. The examination is open to non-residents of New York State.

Applications should be addressed to the Examination Division, State Department of Civil Service, Albany, New York.

> *Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.*

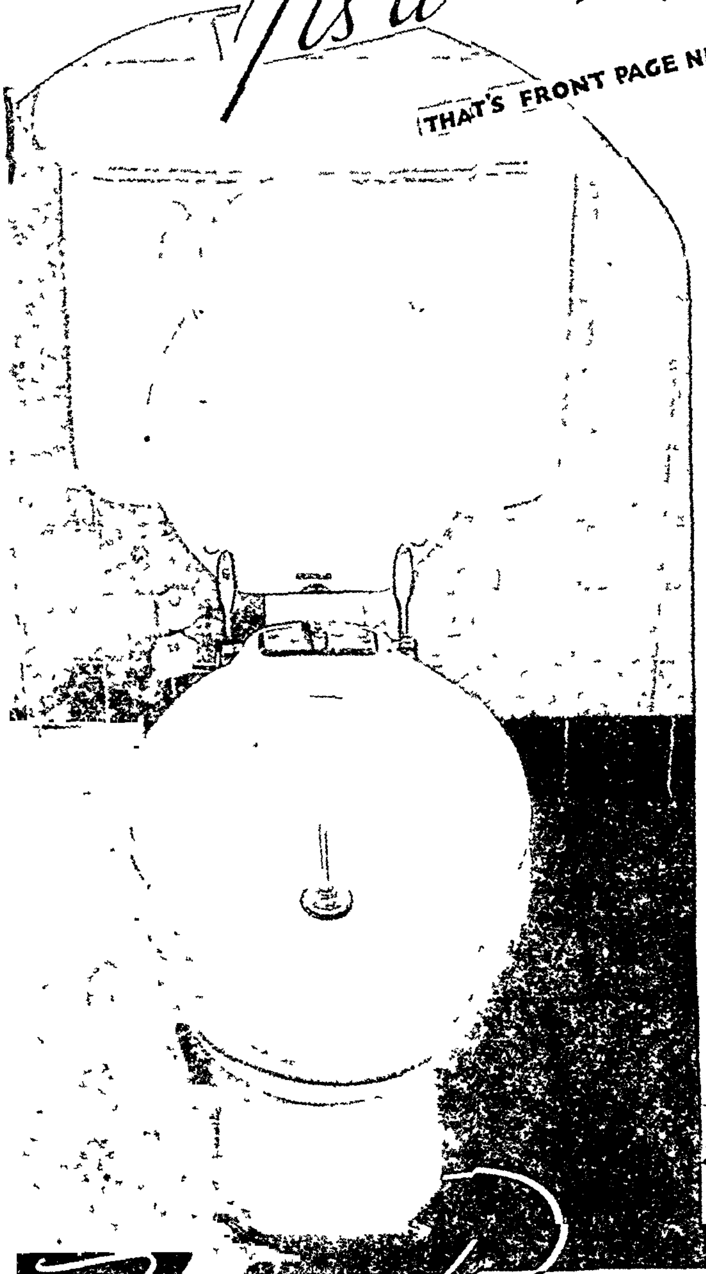
IT PROMOTES HYGIENE . . .

It's a Safeguard to Hea

THAT'S FRONT PAGE NEWS



● THE NU-BIDET is the newest and most outstanding improvement in bathroom fixtures in the past twenty-five years.

The Nu-Bidet is a thoroughly modernized Sitz Bath . . . and more. It has four distinct uses:

- Sitz Bath for personal hygiene.
- Spray for same purpose and for feminine hygiene.
- Attachment for douche and enema, entirely eliminating the old rubber bag method.

The Nu-Bidet is a complete unit of toilet seat, bidet and lid. It replaces the regular toilet seat and lid; is equipped with hot and cold water; completely installed on any standard toilet in two hours.

The Nu-Bidet is as necessary to personal hygiene as a tooth-brush or the bathroom itself. It is an excellent and extremely smart bathroom accessory both for new building and replacement. The roster of the finest homes, hotels and hospitals which have ordered the Nu-Bidet, is a cross section of the "Who's Who in America."

The Nu-Bidet is as new as the latest edition of your newspaper and contains just as much news, from a health and hygiene standpoint. Its installation will give you the newest and most advanced mechanical device yet introduced for safeguarding health. It will convert the ordinary bathroom into one that is thoroughly hygienic at a very moderate investment.

Return the coupon right now while you are thinking about it and full information will be sent. No obligation.

for more than 4 years—

Pernicious Anemia has been adequately and economically treated with

PARENTERAL LIVER EXTRACTS

Lederle

Potent, Clinically Tested Extracts provide for:

- Intensive therapy during the period of relapse with a minimum of inconvenience (*i.e.*, reduced volume and a small number of injections) to the patient.
- Rapid hematopoietic response and general improvement of all symptoms.
- The intensive treatment of cases with marked neurological changes, those having complications and those advanced in years—all of which require more than normal amounts of the antianemic substance.
- Adequate maintenance with injections at intervals of 7 to 20 days.

Authorities on the treatment of pernicious anemia are agreed that the injection of liver extract derived from a certain amount of fresh liver gives an effect equivalent to 30 to 60 times that amount administered orally.

LEDERLE'S latest contribution to the effective and economical treatment of Pernicious Anemia is

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT *Lederle*

ACCEPTED AMERICAN MEDICAL ASSN.

Supplied only in boxes of three 1 cc. vials—each vial containing antianemic substance obtained from 100 grams of liver.

SAVE TIME IN FILTERING WITH PYREX BRAND FUNNELS...

TIME SAVED by the plain Pyrex Brand Funnel with accurate 60° angle has made it so eagerly sought by chemists that now the original size, 65 mm diameter, is supplemented by three other sizes—50, 75 and 100 mm. The unvarying precision of the 60° angle gives more accurate fitting of the filter paper, and reduces filtering time, as compared with an ordinary Bunsen funnel by about *one half.*

And now a further improvement! The accurate 60° angle funnel *fluted.* These flutings greatly increase the effective filtering area, (almost double), and reduce filtering time still further.

Pyrex Brand accurate 60° angle funnels may be had from your regular dealer—plain, in all four sizes; fluted, in the 65 mm size, only. The other three sizes of *fluted* funnels will be available after May 15th.

"PYREX" is a registered trade-mark and indicates manufacture by

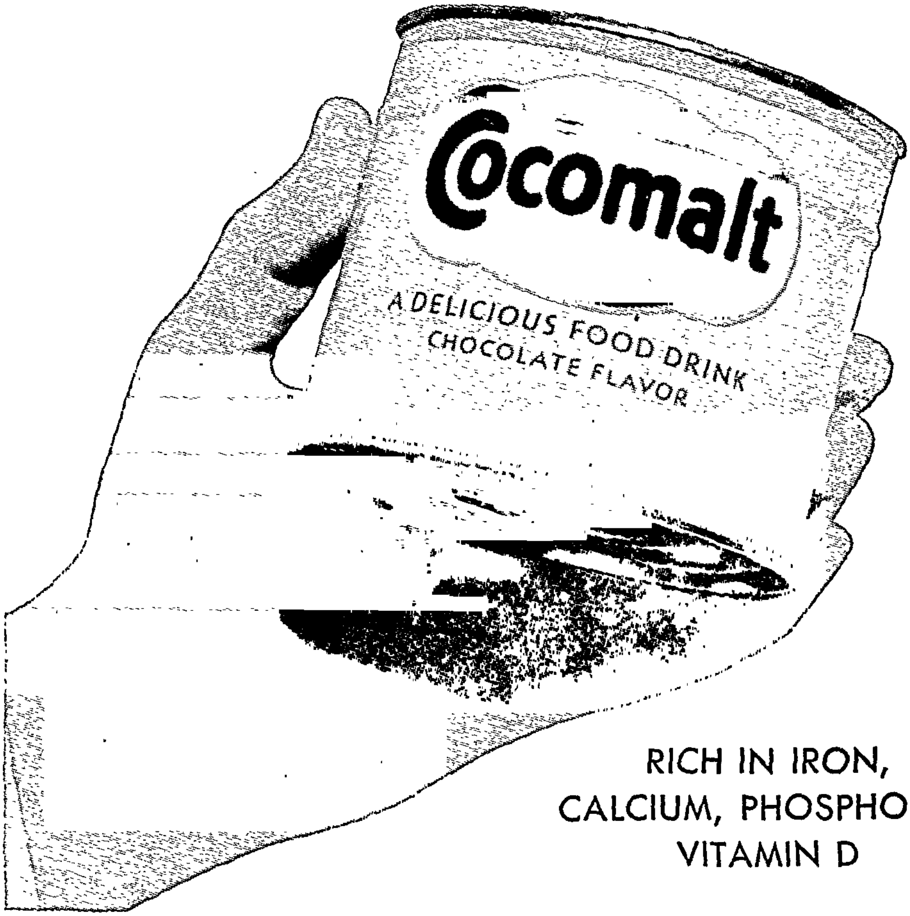
INDEX TO ADVERTISERS



RICH IN IRON,
CALCIUM, PHOSPHORUS,
VITAMIN D

Doctors find many uses for this delicious food-drink

COCOMALT has a rich content of Iron, Calcium, Phosphorus, Vitamin D. An ounce of Cocomalt (the amount used to make one glass) provides 5 milligrams of Iron in easily assimilated form. Three *glasses provide 15 milligrams of available* Iron, the amount recognized as the average daily nutritional requirement.

Each glass of Cocomalt in milk also provides .33 gram of Calcium, .26 gram of Phosphorus, 81 U.S.P. units of Vitamin D.

Helps bring sound sleep

Cocomalt is easily digested, quickly assimilated. It is delicious hot or cold, tempting to young and old alike. Taken hot before retiring, it helps induce sound, restful sleep.

Sold at grocery, drug and department stores in ½-lb. and 1-lb. air-tight cans. Also available in 5-lb. cans for professional use, at a special price.

FREE TO DOCTORS AND NURSES

We will be glad to send a professional sample of Cocomalt to any doctor or nurse requesting it. Simply mail coupon with your name and address.

R. B. Davis Co., Dept. 6-F, Hoboken, N. J.
Please send me a trial-size can of Cocomalt without charge.

Attainable Standards in the Bacterial Counts of Raw and Pasteurized Milk*

M. E. BARNES, M.D., Dr.P.H., F.A.P.H.A.
Department of Hygiene, Preventive Medicine and Bacteriology, State University of Iowa, Iowa City, Iowa

THE study summarized in this paper was made under the following circumstances:

The community surrounding an important state hospital had never had adequate official supervision over the milk supply. All herds in the county had been subjected to the tuberculin test, but few if any were entirely free from infection with Brucella. In fact, Brucella had been isolated from most of the raw milk examined. The commercially pasteurized milk available drew its supply from unsupervised producers, and the bacterial counts often were exceedingly high.

To meet this situation until a more adequate solution was possible, the Children's Hospital improvised a procedure, using a large water-bath to pasteurize milk in bottles. The milk thus pasteurized showed wide fluctuations in bacterial counts, and the dangers of contamination made it urgent that a modern plant be installed. A few months after the organization of a University Department of Health, it became possible to install such a plant and to carry out sanitary inspection of the producing farms as well.

The department took the position that there is not, nor can there be, any such thing as a constantly safe raw milk supply. It held further that the pasteurizing of high count raw milk, however adequate the pasteurization process, could not make such milk desirable for consumption by babies. The least that could be aimed at was Grade A raw milk which had been pasteurized.

On any strict interpretation there were no Grade A dairies in the community. The dairy from which the raw supply was then being received was better than most, but it was decidedly not entitled to a Grade A rating. It was necessary, therefore, to develop such dairies. Unfortunately, financial conditions made it impossible for the university to pay more than the prices locally paid for the higher grades of milk. The chief advantages

---

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

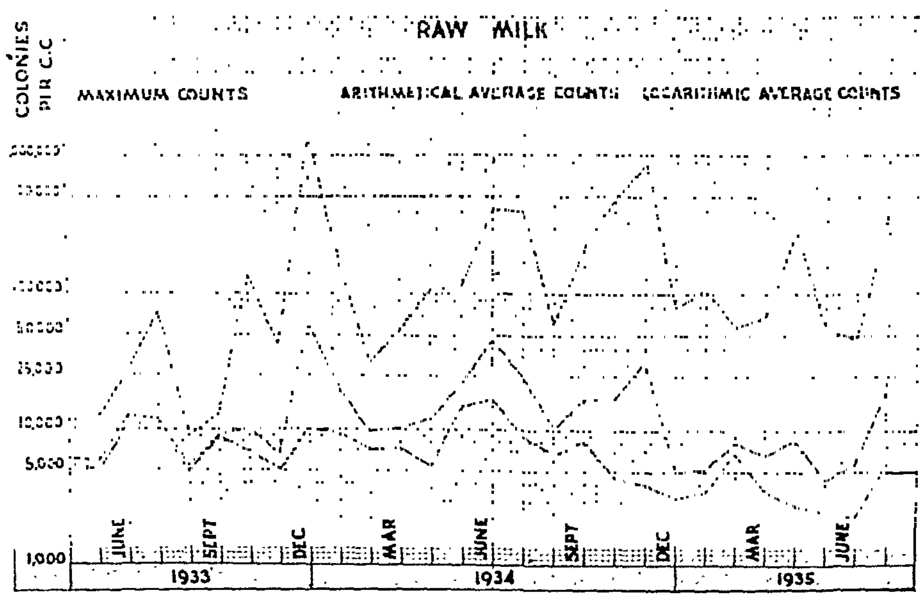
it could offer were stability of market, and freedom from surplussing.

As an example of the general conditions, one of the dairy farms which was later selected may be cited. This producer had been selling so-called Grade A raw milk in the city. On inspection the flanks of the cows were found to be caked with mud and manure, the barn floor was entirely concealed by a closely packed layer of manure several inches in depth, the walls and ceilings of the barn were heavily coated with dust-laden cobwebs, no water was available in the barn, and the milk house was in a poor state of repair. The lower portion of the barn lot was so muddy that the cows mired down if they ventured into it, and a huge accumulation of manure existed within shoveling range of the barn door. It was a grade D dairy. However, a survey showed that beneath the manure was a good concrete floor. The milk house could easily be put into good shape. The installation of water could be economically accomplished. The herd was free from tuberculin reactors, and had only 3 reactors to Brucella.

All that this dairy needed was a producer with a desire and will to remedy its defects. This producer himself said, "All I need is sanitation. If you will show me how, I will do everything required." On inquiry, it was found that he could be depended upon to fulfil his word. In spite of the extremely black picture painted by the inspector as to the requirements, this producer desired to undertake the task. These details are mentioned to show that low bacterial counts are within the reach of almost any dairy which is willing to accept such attainments as an objective. Incidentally, the dairy just described has established the best record thus far made by those in the group herein considered.

The Standard Milk Ordinance was used as a basis for the contracts, but in addition the dairies were required to carry out anything regarded as necessary by the University Department of Health. In correcting defects, first things were placed first, and unremedied

FIGURE I



defects were compensated for temporarily by more rigid efforts along other and more important lines. From the beginning, bacterial counts have been used, not for establishing grades under the ordinance but, primarily, as a means of detecting the development of mastitis and of checking upon the adequacy of the sanitary measures employed.

ATTAINABLE STANDARD FOR BACTERIAL COUNTS IN RAW MILK

Under the Standard Milk Ordinance the maximum standard for Grade A raw milk is set at a logarithmic average of 50,000 per c.c. Occasional high counts cannot be avoided, and the use of logarithmic averages provides a fair means of evaluating the total milk production. Experience over 43 months shows, however, that a logarithmic average of 50,000 is very lenient.

During this period the counts on raw milk ranged from 100 to 1,400,000 per c.c., yet the monthly logarithmic average never reached 50,000. In only 2 months did it exceed 25,000, and in only 4 months did it exceed 10,000 (Figure I). During the last 13 months the monthly logarithmic average never reached 10,000, and it exceeded 5,000 in only 4 months. Thus, a monthly logarithmic average of 5,000 per c.c. seems well within the possibility of attainment.

In this connection it is important to remember that bacterial counts are dependent upon conditions within and without the udder. The trauma which is inseparable from milking favors the development of acute or chronic mastitis and this makes it practically impossible to secure bacteria-free milk. If external conditions are completely controlled, what is the lowest bacterial range which conditions within the udder make possible?

Dorner [1] drew milk aseptically from 132 apparently healthy dairy cows and found that the bacterial counts ranged from 530 to 4,390, the arithmetical average being 2,775 per c.c. In the present studies, specimens were collected from 198 cans of milk produced by a herd of 19 cows. During the first 8 days specimens were taken daily from each can received at the plant. During the following 10 weeks, the specimens were collected weekly. Over this entire period the bacterial counts ranged from 100 to 19,000 per c.c. The arithmetical average was 1,600 and the logarithmic average 1,000 per c.c. This record was made under actual production conditions, the milk being tested as received at the plant. Consequently, it is fair to use it as a basis for determining a zone in which adverse conditions within and without the udder are operative at what is practically their lowest level. For this purpose an arithmetical count of 2,000 per c.c. has been adopted as the upper limit of the ideal zone. All counts above this level indicate a corresponding increase in the factors within or without the udder.

TABLE I

CLASSIFICATION OF BACTERIAL COUNTS IN RAW MILK

Class	*Bacterial Range*	*Interpretation*
I	Under 2,000	Ideal
II	2,000 to 4,900	Excellent
III	5,000 to 9,900	Good
IV	10,000 to 24,900	Fair: Inquiry
V	25,000 to 49,900	Something wrong: Investigate
VI	50,000 to 99,000	Poor: Investigate
VII	Over 100,000	Bad: Investigate

TABLE II

CUMULATIVE PERCENTAGE DISTRIBUTION OF RAW MILK ACCORDING TO BACTERIAL COUNTS

		Period Ending July 31			
Class	*Range of Individual Bacterial Counts*	*1932 7 Mo.*	*1933 12 Mo.*	*1934 12 Mo.*	*1935 12 Mo.*
I	Under 2,000	3.3	0.4	1.8	32.2
I–II	Under 5,000	25.5	24.9	32.8	67.9
I–III	Under 10,000	49.9	64.3	66.8	83.9
I–IV	Under 25,000	76.5	92.3	81.0	93.9
I–V	Under 50,000	84.3	95.4	90.4	97.5
I–VI	Under 100,000	87.8	98.1	95.3	98.7
VII	Over 100,000	12.2	1.9	4.7	1.3
Total specimens examined		90	261	509	1,829
Producing farms		1	1	3	3

In attaining and maintaining low bacterial counts it has been found useful to set up a classification to serve as a goal for the producers, as shown in Table I.

Bearing in mind the conditions under which this work was initiated, it is of interest to observe to what extent the producers have been able to bring their product into Groups I and II which is the goal constantly held before them. The results of 43 consecutive months ending July 31, 1935, are shown in Table II.

All specimens for examination were collected at the plant, iced, delivered to the laboratory between 10 and 11 A.M., and plated in the early afternoon. The plate method, described in *Standard Methods of Milk Analysis,* has been used exclusively. It is recognized that this method is not sufficiently accurate to measure minor deviations. Nevertheless it may be of interest to record the distribution of bacterial counts in Class I, as found in Table III.

THE USE OF MAXIMUM BACTERIAL COUNTS IN EVALUATING PASTEURIZED MILK

The Standard Milk Ordinance uses a logarithmic average of 30,000 per c.c. as a basis for classifying Grade A pasteurized milk. It should be borne in mind that pasteurization is the final factor of safety and that the milk is now ready for distribution to the consumer. There is an inconsistency involved in permitting any high count milk to slip past this final barrier. Inasmuch as the counts indicate viable organisms, it would be logical to judge pasteurized milk not by its arithmetical or logarithmic averages, but by its *maximum* bacterial counts.

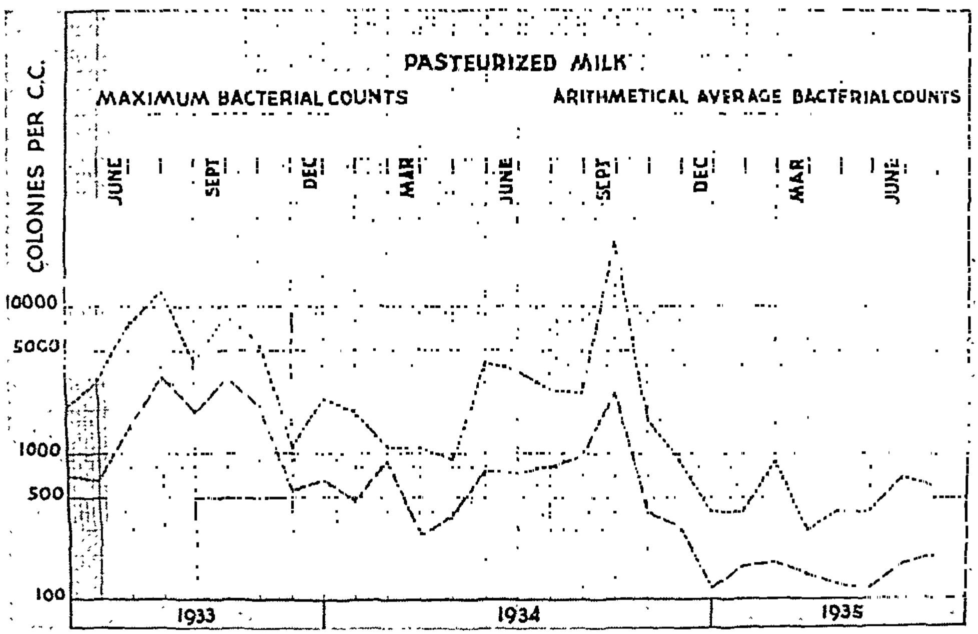
The studies herein summarized cover two periods of 15 and 28 months, respectively. During the first period, the pasteurization was done by an improvised method. The raw milk had

TABLE III

DISTRIBUTION OF BACTERIAL COUNTS BELOW 2,000 PER C.C. IN RAW MILK

Bacterial Count	*Number of Specimens*
1,000 to 1,900	412
Under 1,000	191
Total	603
900	37
800	27
700	26
600	29
500	23
400	22
300	16
200	7
100	4

FIGURE II



bacterial counts ranging from 1,000 to 690,000, the arithmetical average being 30,300 and the logarithmic average 10,000 per c.c. The pasteurized milk showed bacterial counts ranging from 100 to 118,000, the arithmetical average being 2,200 per c.c. In so far as average counts go, this was a very good record. However, 29.8 per cent of the specimens were above 5,000 in bacterial count.

During the second period of 28 months, the milk was handled in a small but modern pasteurizing plant under a well trained operator. The raw milk had bacterial counts ranging from 100 to 1,400,000, with an arithmetical average of 12,500 and a logarithmic average of 4,400 per c.c. In 1,323 specimens of pasteurized milk examined, the range of bacterial counts was from 100 to 13,000, the arithmetical average being 840 per c.c. The distribution of these counts is shown in Table IV.

Throughout the entire 28 months, the monthly arithmetical average bacterial count has exceeded 1,000 only 6 times; the highest being 3,400 per c.c. The *maximum* counts on individual specimens have exceeded 10,000 but twice, 5,000 only 5 times, and in 9 of the 28 months they have been well below 1,000 per c.c. During the final 9 consecutive months, the maximum count on any specimen has been 900, and in 5 of the 9 months has been below 500 per c.c. (Figure II). This performance has resulted practically in establishing 1,000 per c.c. as the standard for the *maximum* bacterial counts, that is, it marks the upper level of the ideal zone. If any specimens reach 2,000 per c.c. the operator and inspector try to find out what is the

TABLE IV

DISTRIBUTION OF BACTERIAL COUNTS IN PASTEURIZED MILK

Range	*Percentage of Total Specimens*
Under 300	52.4
Under 600	68.5
Under 1,000	78.0
Under 2,000	90.1
Under 5,000	97.9
Under 10,000	99.5
Under 25,000	100.0

matter. No importance is attached to such minor changes, but the only way to maintain low counts is to hold before those responsible a definite standard of excellence toward the attainment of which they may direct their efforts.

SUMMARY

This paper summarizes the studies of milk production over 43 months during which a raw milk supply was being developed under somewhat adverse conditions. Bacterial counts were used, not as a means of grading the milk but as a check upon the influence of mastitis and environmental factors. Under actual production conditions, raw milk was delivered to the plant from May 16 to July 31, with an arithmetical average bacterial count of 1,600, the individual counts ranging from 100 to 19,000 per c.c. On the basis of this performance a bacterial count of 2,000 was regarded as the upper limit of an ideal zone within which mastitis and environmental factors are reduced to the minimum. All counts in excess of this level are regarded as indicative of the operation of one or both of these factors. A classification on this basis provides a guide as to these factors and a goal for the producer. The data show that during the last 12 months, 32.2 per cent of the raw milk from 3 dairies was within this ideal zone, and 83.9 per cent was under 10,000 in bacterial count. The experience of the final 12 months indicates that a logarithmic monthly average of 5,000 seems within the possibility of attainment. The physical equipment of these dairies was such as can be developed at reasonable expense in any community.

Similar studies in pasteurized milk led to the rejection of both arithmetical and logarithmic averages, and the use of maximum bacterial counts as the criterion of excellence, 1,000 per c.c. being regarded as the upper limit of the ideal zone. The data show that this ideal zone was maintained during the final 9 months, the highest count found being 900 per c.c. During 5 of the 9 months, the maximum counts failed to exceed 500 per c.c.

Some Epidemiological Aspects of Chronic Endemic Dental Fluorosis*

H. TRENDLEY DEAN, D.D.S., AND ELIAS ELVOVE, PH.D.

Dental Surgeon, and Senior Chemist, U. S. Public Health Service, Washington, D. C.

THE endemic hypoplasia of the permanent teeth known in this country as mottled enamel was first reported by Eager[1] in 1901. The first investigation in the United States was the extensive one of Black,[2] and McKay,[3] published in 1916. At present in this country alone there are more than 200 areas where endemic mottled enamel has been confirmed by survey; in addition there are approximately 100 areas where the endemicity has been reported but not confirmed by survey. These approximate 300 areas are distributed among 23 different states.

The incidence of affection in an endemic area is relatively high, often 90 per cent, and in some instances all children exposed throughout the period of calcification of the teeth are affected. In the light of present knowledge, mottled enamel is a water-borne disease associated with the ingestion of toxic amounts of fluoride present in the water used for drinking and cooking during the period of tooth calcification. The minimal threshold has not yet been definitely established but studies to date would suggest that amounts below 1 p.p.m., expressed in terms of fluorine (F), are of no public health significance.

There is apparently no race, color, or sex differential. With respect to the teeth, the causative factor is operative only during the period of calcification, which, with the exception of the third molar represents approximately the first decade of life. There is some indication [4] that the skeletal system might likewise be affected; if this is true, it would be necessary to extend the time range to include adults.

The macroscopic pathology in the human has been classified according to severity thus: normal, questionable, very mild, mild, moderate, moderately severe, and severe. These various gradations have previously been described.[5] This classification, depending on the degree of severity of the affection, permitted in turn the development of the following "mottled enamel indexes" of a community [6, 7]: negative, border-line, slight, medium, rather marked, marked, and very marked. Several detailed studies [8, 9, 10] concerning the histopathology of this disease have been reported. An analogous hypoplasia developed under natural conditions has been observed in certain domestic animals.[11, 12] The sole hope in the solution of this problem lies in prevention. Since the ameloblasts cease functioning at the time of eruption of a tooth, such

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

ameliorative treatment as is possible is naturally very limited in scope and generally unsuccessful. Bierring[13] in referring to this disease recently has recorded that "although different in nature from typhoid fever, [it] represents a permanent physical defect of distressing character."

Mottled enamel has direct relationships to other forms of oral pathology, some of these relationships being at times paradoxical. In spite of their defective structure, mottled enamel teeth, according to McKay,[14] exhibit no greater liability to caries than do normally calcified teeth, an inference apparently sustained by the investigations of Masaki,[15] Ainsworth,[9] and Erausquin.[16] Masaki[15] and Ainsworth,[9] in addition, maintain that the eruption of the secondary dentition is delayed.

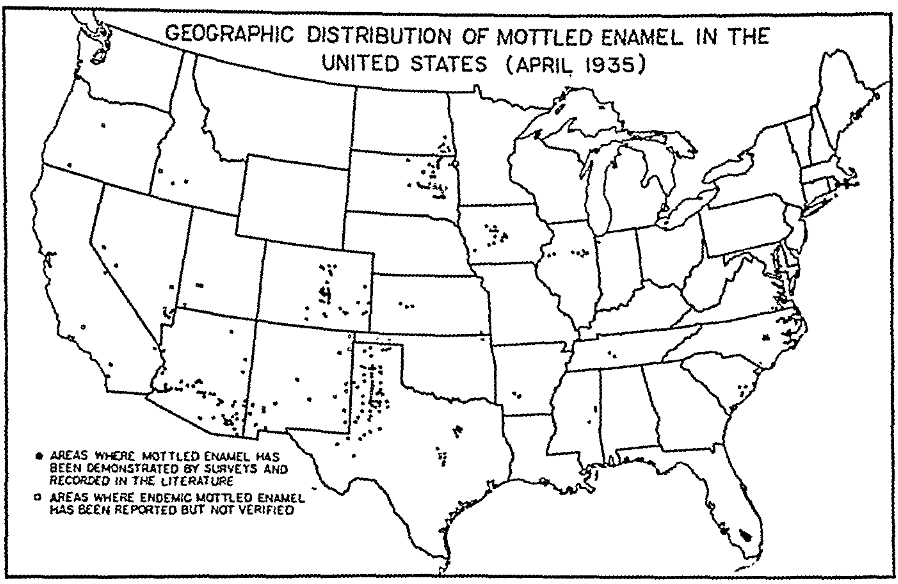
From observations made by one of us (HTD) in areas of relatively high fluoride concentration (more than 4.0 p.p.m.) there is, likewise, sufficient evidence to suggest an apparent tendency to a higher incidence of gingivitis (Figure I).

POSSIBILITY OF ERROR IN NON-QUANTITATIVE STUDIES

A review of the literature indicates that surveys of the past have been largely non-quantitative. In many instances data of little value are submitted relative to two important conditions, namely, (a) the number of children in the group studied, together with the length of time of their constant exposure, and, (b) possible changes in the chemical composition of the water used during the life period of the group examined.

The number in the group examined should consist of at least 25 children 9 years of age or older who had used the water under investigation continuously since birth for both drinking and cooking. Breaks in continuity totaling less than 30 days in any one calendar year are excepted. In instances where the examination of the first 25 children discloses an incidence of less than 75 per cent, the number in the group examined should be increased to at least 50, if possible. In other words, when more than 25 per

FIGURE I



cent are diagnosed as "normal" or "questionable," the size of the group examined should be increased to compensate for fluctuations in sampling and their possible effect on the computation of the community mottled enamel index.

Studies of the past have, in most cases, failed to take into consideration what has recently been revealed by carefully conducted surveys which included the individual water histories of each child re-checked by an interview with the child's parent. These surveys [7] have shown, at least with respect to the 9 year old group in the 4 cities studied, that only about 20 per cent used the city water continuously from birth.

The need for an adequate clinical sample is obvious when we consider that the causative factor of mottled enamel is probably operative during the entire period of calcification of the permanent teeth; and an observed effect may be the result of a comparatively low fluoride concentration operating during the entire period, or a relatively high concentration for a shorter period. In endemic areas where the domestic water contains a fluoride concentration only slightly above the minimal threshold, the production of visible signs of mottled enamel in the susceptibles of the group examined would probably depend upon the continuous use of the water during the entire period of calcification. On the other hand, in areas where the domestic water contains a comparatively high fluoride concentration, its use during a part of the period of calcification is sufficient to produce observable mottled enamel. A careful analysis of the data from the Bauxite survey [17] makes this latter point apparent.

Because of possible changes in the fluoride content of water supplies, it is obvious that an attempt to correlate clinical observations with a single fluoride determination of a municipal water associated with endemic mottled enamel introduces the possibility of questionable correlation. In respect to water from deep wells, the fact that the mineral content usually varies within comparatively narrow limits might be misleading until it has been definitely ascertained that there have been no changes in the physical set-up of the water supply during the lifetime of the children. Hence the amount of fluoride in a water sample taken at the time of the clinical examination may mean little unless a complete history of the water supply concomitant with the life of the children examined, has been obtained.

It must also be borne in mind that some municipalities using deep wells for their common water supply have more than one source of deep well water. For instance, the largest city in the United States known to be affected with mottled enamel regularly uses water from one group of wells for 6 months of the year, and from an entirely different group for the other 6 months. This rotation has been followed for the past 4 years, and since one supply has about twice as much fluoride as the other, it is evident that a single sample representing only one of these supplies would be valueless in correlating chemical findings with clinical observations. Moreover, the addition of new wells, or the abandonment of old ones during the lifetime of the group examined may introduce variable factors that would make it impossible to draw reliable conclusions from the chemical findings disclosed at the time of the examination. Furthermore, in dealing with surface waters or shallow wells, the seasonal and annual rainfall or other meteorological conditions become factors of importance. In this study, therefore, consecutive monthly water samples were obtained for 1 year and a fluoride determination was made on each sample.

* The Amarillo municipal water is obtained from two sources: October to March, inclusive, each year from the McDonald wells. April to September, inclusive, each year from the Palo Duro. In September, 1934, the city water was obtained from the McDonald supply on account of a break-down in the lines of the Palo Duro supply. In October, 1934, the water used in the city was from the Palo Duro; in November, the supply was again obtained from the McDonald wells.

PRESENT STUDY

This paper presents a comparison of the results obtained in the investigation of the following 10 cities: Monmouth and Galesburg, Ill.; Colorado Springs and Pueblo, Colo.; Lubbock, Amarillo, Plainview, and Big Spring, Tex.; and Conway and Mullins, S. C.

The detailed results, including chemical analyses, noted in the study of the Illinois and Colorado areas have been reported.[7] An approximate mottled

* These samples of water from Lubbock, Plainview, and Big Spring were received in November, 1934; the sample from Amarillo, in August, 1934; and those from Conway and Mullins, in October, 1934. Assistant Chemist C. G. Remsburg carried out the determinations other than fluoride and boron, using mostly the methods given in the *Standard Methods of Water Analysis* of the American Public Health Association. The boron determinations were made essentially by the method of Foote.[19]

enamel index of each of the 4 Texas cities has already been reported,[6] but the chemical data are included in the present paper. Furthermore, there are included in this report, for comparative purposes, chemical findings of and certain relevant clinical observations from a recently made study in South Carolina.

The fluoride content of the monthly samples of water was estimated colorimetrically by means of the zirconium-alizarin reagent.[18] The results obtained are given in Table I.

As has been pointed out previously,[7] it may be reasonable to suppose that the mottled enamel index will be found to depend entirely on the fluoride concentration of the drinking water; but it is possible, on the other hand, that other constituents of the water may have some influence on the activity of the fluoride. For this reason it appears desirable that a careful survey of a community for chronic endemic dental fluorosis should include also, for the present at least, a chemical analysis of the drinking water for constituents other than fluoride. Results of the chemical analyses of the waters from the South Carolina and Texas cities are given in Table II.

The water histories, especially with respect to variation, and other comparative data obtained in the study of the 10 cities referred to are given in Table III.

DISCUSSION

An analysis of the history of the common water supply respecting continuity clearly indicates the extreme caution necessary in attempting to correlate clinical observations including verified water biographies, with a single fluoride determination or even an annual arithmetical mean of the fluoride content when the communal water supply itself contains one or more extrinsic variables. In more than half of the cities in the group there are sufficient interruptions to warrant caution

FIG. II

SEVERITY OF MOTTLED ENAMEL IN CHILDREN OF TEN SELECTED CITIES AND THE MEAN ANNUAL FLUORIDE (F) CONTENT OF THE MUNICIPAL WATER SUPPLY 1933-34.

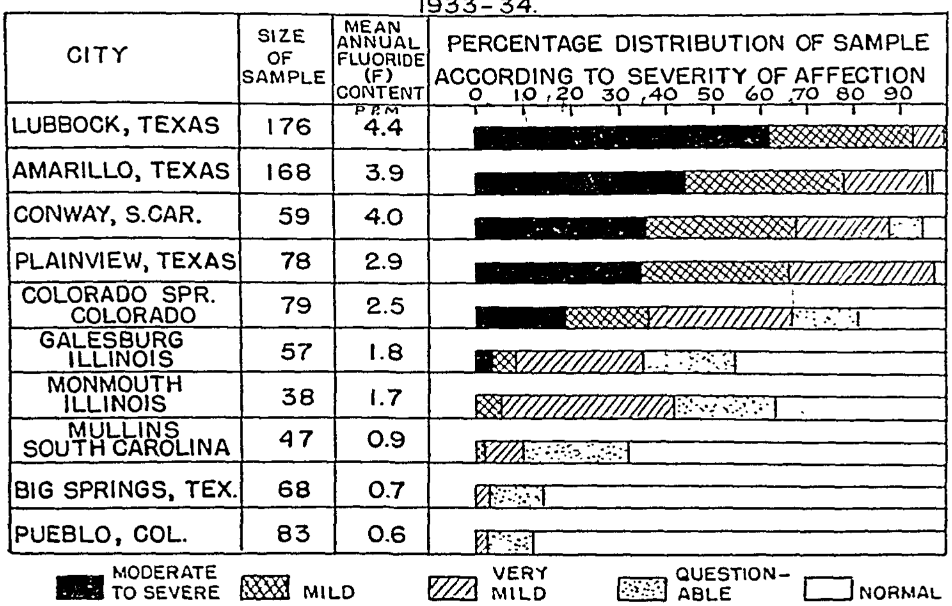

TABLE III

WATER HISTORIES AND OTHER COMPARATIVE DATA OF THE CITIES STUDIED.*

City and State	Population (1930)	Description of Water Supply with Respect to Variation	Quantitative Evaluation: Presence or absence of requisites	Quantitative Evaluation: Classification	Clinical: Age group or school grade examined	Clinical: Number of children examined who stated they had used municipal water continuously	Clinical: Number showing mottled enamel	Clinical: Incidence	Mottled enamel index of the community	Mean annual fluoride (F) content (1933–1934) (parts per million)
Colorado Springs, Colo.	33,237	Surface supply; melted snow from Pike's Peak stored in 7 mountain reservoirs 9,300′ to 12,000′ in altitude. No changes in present supply during past 20 years.	Present	A	9 year old	79	53	67.0	slight	2.5
Monmouth, Ill.	8,666	Since 1925 from two 2,445′ wells drilled to the "Potsdam" stratum of the Cambrian sandstone. Upper water-bearing strata cased off.	Present	A	9 year old	38	16	42.1	slight	1.7
Mullins, S. C.	3,158	Municipal water supply obtained from 2 deep wells, 350′ and 360′ deep and drilled in 1913 and 1921, respectively.	Present	A	9, 10, 11 years old	47	5	10.6	negative-border line	0.9
Pueblo, Colo.	50,096	Surface supply; Arkansas River. Samples taken from North Pueblo supply; clinical examinations likewise limited to children in northern half of city. North Pueblo supply from same source during past 46 years.	Present	A	9 year old	83	2	2.4	negative	0.6
Lubbock, Tex.	20,520	Municipal supply obtained from 8 wells, #1 (1925), #2 (1917), #3 and #4 (1924), #5 (1928), #6 (1930), #7 (1931), and #8 (1934). City water in general is a composite of these various wells distributed from 5 reservoirs in which water from specific wells is impounded. No. 4 well furnishes about 25% of the supply; Nos. 1, 2, 5, and 6 about 15% each, and Nos. 3, 7, and 8 about 5% each. Depth ranges from 140′ to 150′; all wells have perforated casings through each water bearing stratum. About half of the time only 2 pumps are operated and one section of the city may be served by one or two wells and another section by another well or group of wells.	Absent	B	4th 5th 6th grades	176	174	98.8	marked	4.4
Amarillo, Tex.	43,132	Prior 1927 from 35 wells, 250′ deep, located in various parts of city. In 1927 Palo Duro supply, 20 mi. SW of city consisting of 10 wells, 180′ deep, installed, and used exclusively until 1931 when McDonald supply consisting of 5 280′ wells, 7 mi. SW of city was installed. Since 1931 municipal supply from two sources: Oct.-March inclusive each year from McDonald wells; April-Sept. inclusive each year from the Palo Duro.	Absent	B	4th 5th 6th grades	168	162	96.4	rather marked	3.9

* Clinical examinations at Monmouth and Galesburg, Ill., were made during October, 1934; those of the 4 Texas cities during November, 1934, Colorado Springs and Pueblo, Colo., during April, 1935, and Mullins and Conway, S. C., during September, 1935.

TABLE III—Continued

WATER HISTORIES AND OTHER COMPARATIVE DATA OF THE CITIES STUDIED.*

City and State	Population (1930)	Description of Water Supply with Respect to Variation	Quantitative Evaluation: Presence or absence of requisites	Quantitative Evaluation: Classification	Clinical: Age group or school grade examined	Clinical: Number of children examined who stated they had used municipal water continuously	Clinical: Number showing mottled enamel	Clinical: Incidence	Mottled enamel index of the community	Mean annual fluoride (F) content (1933–1934) (parts per million)
Conway, S. C.	3,011	Municipal water supply is obtained from 3 artesian wells, a 3½" well drilled in 1896, 450' deep; a 10" well drilled in 1918, 400' deep, and a 3" well drilled in 1927, 305' deep. All wells cased entire depth. Casings of the 400' and 450' wells have "slots" at the higher water bearing levels and water from these 2 wells represents a composite of more than one water bearing stratum. About 85% of the city water is obtained from the 10" well; the remainder from the 305' well. Well drilled in 1896 supplies negligible amount. Analysis of a sample from each of the 3 wells shows slight variation in the fluoride (F) content; approximately 0.2 p.p.m.	Absent	B	9, 10, 11 years old	59	52	88.1	rather marked	4.0
Plainview, Tex.	8,834	Prior to 1926 from 2 wells, 95' and 175' deep (old supply); 1926–1928 from one well 275' deep (new supply). From 1928 to date supply is a composite one, 75% from "new" supply and 25% from "old" supply. All wells within city limits are "gravel backed" thus permitting water from different strata to mix.	Absent	B	5th 6th 7th 8th grades	78 †	76 †	97.4	rather marked	2.9
Galesburg, Ill.	28,830	Since 1928 from 2 2,414' wells drilled to the "Potsdam" stratum of the Cambrian sandstone. During 1924–1928, 60% of municipal supply from first 2,414' well and 40% from 2 wells in St. Peters sandstone, 1,245' and 1,252' deep.	Absent	B	9 year old	57	20	35.1	slight	1.8
Big Spring, Tex.	13,735	Municipal supply obtained from 23 wells. One-third of supply from 13 wells, 260' deep drilled in 1923. Two-thirds of supply from 8 wells, 280–300' deep, drilled in 1927. During 1894–1923 all municipal water from "Old Park" supply, which was supplemented until 1927 by 1923 group of wells. During 1927–1933, "Old Park" supply shut down. Between Nov., 1933, and May, 1934, 1927 group of wells also shut down. Wells located 2, 6, and 9 miles, respectively, south of Big Spring.	Absent	B	5th 6th grades	68	2	2.9	negative	0.7

* Clinical examinations at Monmouth and Galesburg, Ill., were made during October, 1934; those of the 4 Texas cities during November, 1934, Colorado Springs and Pueblo, Colo., during April, 1935, and Mullins and Conway, S. C., during September, 1935.

† Large part of 1934 sample calcified their teeth while using "old" water supply, the "F" content of which is unknown. Recent survey (March, 1936) shows incidence of 87.6 and index of "medium."

in attempting to correlate clinical observations with the composition of the water at the time of the clinical survey.

The application of epidemiological principles for the purpose of determining a minimal threshold of toxicity produced under natural conditions presupposes that inferences shall not be drawn from studies of cities in which there is an interfering relevant variable in one or both of the factors which are to be correlated. The magnitude of the population of these 10 cities makes possible a clinical examination of a sufficiently large sample in each community having the essential characteristic of continuously using a common water supply for domestic purposes. But when an attempt is made to correlate the mottled enamel index of the community with the mean annual fluoride content, only 4 of the cities are appropriate for quantitative evaluation; in the others, an approximate evaluation only is possible.

With respect to an adequate clinical sample, it has been found desirable, if not necessary, in instances where the examination of the first 25 children discloses an incidence of less than 75 per cent, to increase the minimal number of the group, whenever possible, to at least 50. In other words, when more than 25 per cent are diagnosed "normal" or "questionable," the increase in the number examined naturally tends to compensate for the fluctuation in sampling and its corresponding influence on the computation of the community mottled enamel index.

The data obtained in the study of these 10 cities and the fact that many reports in the literature generally omit inherent basic data required for epidemiological purposes suggest the classification of endemic areas under three heads:

Class A—Communities where the requisites for a quantitative evaluation are present and have been analyzed

Class B—Communities where changes in the source of water supply and/or population preclude quantitative evaluation. In some instances, however, a careful analysis of the variable factor or factors may suggest an approximate evaluation

Class C—Communities which have been reported in the literature as affected with chronic endemic dental fluorosis (mottled enamel) but where the requisites for a quantitative evaluation were not stated.

In this study, Colorado Springs, Colo.; Monmouth, Ill.; Mullins, S. C., and Pueblo, Colo., are illustrative of Class A. Lubbock and Amarillo, Tex.; Conway, S. C.; Plainview, Tex.; Galesburg, Ill., and Big Spring, Tex., would come under Class B. A high percentage of endemic areas previously reported in the literature would be classified under C.

SUMMARY

1. The requisites for a quantitative evaluation of an area showing chronic endemic dental fluorosis (mottled enamel) are: (a) a common water supply whose history discloses no relevant changes in either its physical set-up or its source during the period concomitant with the life of the group examined; and (b) clinical examinations, the observations recorded quantitatively, of a minimum of 25 children, 9 years of age or over, who have used a common water supply continuously since birth for both drinking and cooking. Breaks in continuity totaling less than 30 days in any one calendar year are excepted. Moreover, in instances where the examination of the first 25 children discloses an incidence of less than 75 per cent, an attempt should be made to increase the number of children to 50 or more in order to compensate for fluctuation in sampling.

2. For the purpose of quantitative study, affected communities are classified on the basis of the presence or absence of the requisites for quantitative evaluation, as follows: Class A in-

cludes communities where the requisites for a quantitative evaluation are present and have been analyzed; Class B includes those where changes in source of water supplies and/or population make impossible the determination of a quantitative evaluation; and Class C includes communities which have been reported as affected with mottled enamel without stating whether the requisites for a quantitative evaluation are present or absent.

3. The percentage distribution of severity permits the computation of an actual or approximate "mottled enamel index" of an affected area. This index in turn may be correlated with the fluoride content of the water supply, expressed as an arithmetical mean of 12 consecutive monthly determinations.

Whooping Cough in Surveyed Communities*

EDGAR SYDENSTRICKER, F.A.P.H.A.,† AND
RALPH E. WHEELER, M.D., F.A.P.H.A.
Scientific Director, and Research Associate, Milbank Memorial Fund, New York, N. Y.

AS it is chiefly in the light of a definitely ascertained incidence that the relative importance of various modes of spread may be determined and the effectiveness of various control measures gauged, the basic question in the epidemiology of any disease is the determination of its incidence. In the case of the acute communicable diseases of childhood, a number of factors have directed attention away from incidence determinations. Among such factors could be mentioned the variable prevalence over short periods of time, the general reliance upon mortality to the exclusion of morbidity data, the inadequacy of the information furnished in many of the diseases by notification, and the cost of obtaining complete reports.

The present data are the results of field work in several communities in the United States under the auspices of the U. S. Public Health Service in collaboration with the Milbank Memorial Fund. The method is essentially that of a periodic canvass of a representative sample of white families in a stated area and the recording of pertinent data on interval illnesses—in the present instance, on attacks of whooping cough. Where a physician had seen the case, his diagnosis was obtained. At the start of each survey, the date of birth, sex, and previous history of whooping cough were recorded for each person; and similar data, together with the date of entrance, are recorded for each new arrival in the population under observation. All departures through change of residence and also deaths are recorded so that the number of persons under observation is known.

Two general types of survey are included in the present report. The first, which will be styled "local survey," was performed by essentially the same well trained field staff in 3 different localities—Cattaraugus County, N. Y., Hagerstown, Md., and Syracuse, N. Y. It will be noted that these represent 3 widely differing types of community. Cattaraugus is predominantly rural, with a very small village population, Hagerstown is a small city of some 30,000 persons, and Syracuse a relatively large one of approximately 200,000 inhabitants.

The second or "general survey" was the study conducted by the research staff of the Committee on the Costs of Medical Care, from which the whooping cough data have been made available through the kindness of Selwyn D. Collins, of the U. S. Public Health

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

† Deceased.

TABLE I

DATE, DURATION, AND NUMBER OF PERSONS OBSERVED FOR SPECIFIED SURVEYS

Community	*Date of Survey*	*Duration of Survey in Months*	*Average Number of Persons Observed*
Local Surveys			
Cattaraugus County Rural Area, N. Y.	1929–1932	36	4,940
Hagerstown, Md.	1922, 1923	28	7,079
Syracuse, N. Y.	1930, 1931	18	4,962
General Survey, Costs of Medical Care			
Rural	1928–1931	12 *	7,825
Towns and Villages less than 5,000	" "	"	8,964
Towns and Cities 5,000–100,000	" "	"	10,942
Cities Over 100,000	" "	"	15,240

* Although the period of observation of any one community was only 12 months, the field work in the several communities included in each category was spread over a period of 40 months.

Service, with which the committee's morbidity records were deposited for further analysis. This was a large survey performed in 18 states in various types of community and including some 9,000 white families. Unlike the local studies, the field staff for this survey was not previously trained in morbidity surveys, and varied in each of the many localities in which the work was performed. These factors gave rise to some uncertainty when the question of using the Costs of Medical Care data was considered, but it will be seen that the general survey rather strikingly confirms the local surveys, and that its figures have a more truly average value by virtue of the distribution of the field work in numerous areas, and over a period of years.

The local survey populations were much more representative of the population of the communities in which the studies were made, as the general survey of the Committee on the Costs of Medical Care included primarily families of 2 or more persons. The special characteristics of the latter populations and methods of collecting data have been outlined by Collins.[1] The essential point is, however, that both types of survey include fairly large populations accurately determined, and that the cases of whooping cough occurring in them during more or less prolonged periods of observation have likewise been quite accurately recorded. The size of the populations studied, the date, and the duration are given for each survey in Table I.

This report will make use only of the information obtained from these studies on: (1) case fatality, (2) histories of attack, and (3) attacks of whooping cough during the period of observation. The data obtained in the 3 categories will be compared and certain deductions as to the incidence of whooping cough will be made.

CASE FATALITY

In Table II have been assembled the cases and deaths recorded for the surveys embraced in this report. It will

TABLE II

CASES, DEATHS, AND CASE FATALITY FOR SPECIFIED SURVEYS

	Cases	*Deaths*	*Case Fatality Per Cent*
Cattaraugus 1929–1932	280	None	....
Hagerstown (Survey) 1922, 1923	374	None	....
" (whole city) 1922, 1923	(1,538)	(3)	0.20
Syracuse 1930–1931	93	None	....
Costs of Medical Care 1929–1933	841	3	0.36
All Surveys	1,588	3	0.19

be noted that no deaths were observed in the 3 local surveys, Cattaraugus, Hagerstown, and Syracuse, although 3 whooping cough deaths, all in persons not included in the survey, were registered for Hagerstown during this period. When the rates for whooping cough in the sample population were applied to the total white population of this small city, a total of 1,538 cases was obtained, the case fatality being 0.20 per cent. The case fatality of 0.36 per cent for the Costs of Medical Care survey was somewhat higher. It is seen to be based, likewise, upon a very small number of deaths, so that chance variations in the latter could affect it markedly. However, there is a certain amount of evidence which would indicate that the observed rate is typical. At Dr. Collins's suggestion, the mean age-specific whooping cough mortality rates for white persons in the registration area in 1930–1931 were applied to the person-years of observation of the Costs of Medical Care Study, and the figure of 3.2 deaths so obtained tallies closely with the observed number.

The figures for whooping cough case fatality based upon notified cases and registered deaths commonly show a considerably higher rate even when the factor of incompleteness of reporting is controlled. This raises the question of whether there may not be a fairly high proportion of cases of chronic bronchitis included in the survey series of cases. As only about 50 to 70 per cent of the cases were attended by physicians, it was not always possible to obtain a medical confirmation of the diagnosis. The lay criterion for whooping cough is based chiefly upon the crowing inspiration which follows the attacks. It is therefore felt that the majority of these non-attended cases were actually overt whooping cough and that, if anything, they represent an under- rather than an overstatement.

Confirming these low survey figures, several indirect measurements of case fatality are to be found in the literature. Henderson [2] obtained the figure 0.2 per cent for London, Ontario, from data based upon histories of attack among children under 20 years of age, and Sydenstricker and Collins,[3] from histories of illness and of death in Cattaraugus, obtained an estimate of 0.33 per cent. Using somewhat the same method as Henderson, Collins [4] estimated the case fatality in children under 15 years of age at 0.54 per cent for the United States as a whole.

In the 5 year period 1929–1933, there occurred among white persons in the United States Registration Area an average of 4,500 deaths yearly from whooping cough. This probably represents a minimum, as it is generally felt that an undetermined number of deaths from whooping cough each year is listed under pneumonia. If whooping cough were a disease with a high case fatality, this would not imply a very great prevalence, but the case fatality is evidently not high. If the figure obtained from the Costs of Medical Care study, which is intermediate in relation to these various estimates, be taken as fairly reliable, the average of 4,500 deaths in the registration area represents 1,250,000 cases annually among white persons in that area. This method of estimating the number of cases has numerous limitations, but it at least shows in a general way the extremely high prevalence of the disease.

INCIDENCE

In obtaining incidence rates for whooping cough and many other illnesses, 3 general sources of data may be used: (1) reported cases, (2) recorded histories of attack, (3) recorded cases by morbidity survey.

That useful information may be obtained from analysis of reported cases

has been shown by Godfrey.[5] However, the fact that only about half of all cases are seen by physicians, and that but a small proportion of those so seen are reported, makes the data in this country seem of doubtful value when general incidence figures are to be obtained. In Scotland, Laing and Hay[6] and in England, Stocks[7] have published valuable studies of general incidence in cities, but the question still remains of how fully notification is achieved or, in the case of Stocks's work, of how completely it has been possible to allow for unreported cases.

It would appear that recording the percentages of individuals with a remembered history of prior attack of whooping cough, as has been done in this country by Henderson, Collins, Lombard, Scamman, Doering, and others, offers extremely useful data on prevalence. It is open to the objections that the incidence may have changed in recent years and that the memories of persons giving the histories may be fallible, but on the whole the data so obtained reflect surprisingly accurately the prevalence within the period covered and the method of collection is relatively inexpensive.

The data obtained by morbidity survey are perhaps the most complete if the survey is extensive enough and if it covers a sufficiently long time so that epidemic influences are controlled. When, as in the case of the surveys here reported, history data are combined with observations on current attacks, it is believed that a very definite picture of the incidence may be secured. The incidence measured in both cases is only that of overt attacks of whooping cough.*

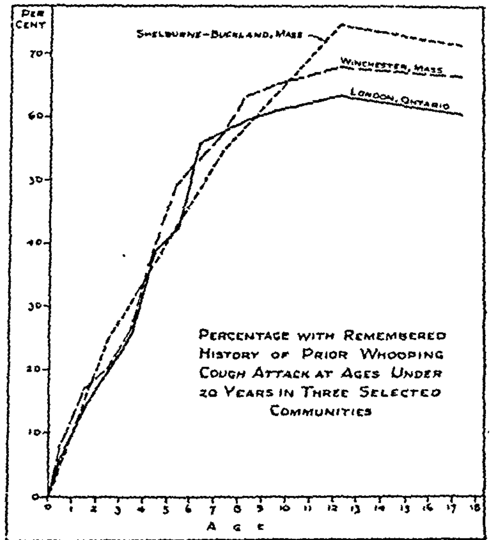

FIGURE I

It is proposed first to outline briefly the information obtained by recording the per cent at each age with remembered history of attack prior to the beginning of the surveys. In *Figure I* are shown curves giving these percentages for 3 communities recorded in the literature: Shelburne-Buckland, Mass., reported by Lombard and Scamman,[8] Winchester, Mass., reported by Scamman and Doering,[9] and London, Ontario, reported by Henderson.[2] Shelburne-Buckland represents a rural township population, Winchester a town of some 11,000 persons, and London, Ontario, a city of about 40,000 population. They are all on the same parallel of north latitude, a point which may be important, as there is some evidence that southern communities in this country show higher percentages with history of previous attack. The curves have been plotted only to 20 years of age, as histories are unreliable at older ages.

It will be noted that the more rural Shelburne-Buckland curve reaches a higher level, although it climbs somewhat more slowly. The level is about 75 per cent. The Winchester curve falls between the former and the Lon-

* There is a good deal of evidence that overt attacks are only one factor in immunization against whooping cough. Stocks (*loc. cit.*) has postulated a transient immunity in individuals exposed but not overtly attacked, and one other possible factor of a more permanent nature.

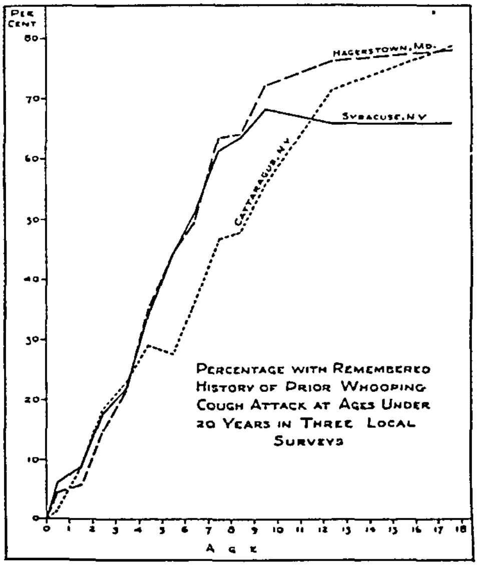

FIGURE II

don, Ontario, curve, the last reaching a level at about 64 per cent.

Figure II shows this same phenomenon for the 3 local surveys of Cattaraugus, N. Y., Hagerstown, Md., and Syracuse, N. Y. Here there is a definite difference between the levels reached by the rural and the large city groups, but the Hagerstown curve, which theoretically should lie between, actually reaches essentially the same level as the rural curve. This may be due to the possibility, mentioned above, that more southerly placed communities tend to show larger percentages.

Figure III shows this same data for the communities of varying size in the Costs of Medical Care study.

It will be noted in general that the curve for rural areas tends to rise *somewhat more slowly, and that at 18* years of age it may still be rising, whereas the corresponding urban curves reach a somewhat lower level at 13 years of age or less. Translated into terms of incidence, this means that the smaller communities tend to have a lower attack rate at the earlier ages, and a higher one in the later years, and that they show a higher general incidence at ages under 20 years. This translation in statistical terms can be made quite accurately from these very curves, as Henderson and Collins have shown. Thus an average annual incidence below a given age can be obtained by dividing the percentage with prior history at the given age by the number of years from birth to that age. The figure would be the per cent attacked annually, and this multiplied by 10 would be average annual attack rate per 1,000. A rate so obtained would be, in a sense, standardized for age. It will be noted, however, that some of the curves shown in Figures I–III do not approach an asymptote but actually decline after age 15. There is good reason for believing that this is not due to a lower prevalence of whooping cough 15 or 20 years before the survey, but is an artefact dependent upon the inability of some informants to remember attacks occurring many years before. In obtaining by the above method the average annual incidence rates under the age of 20, entitled " Rates from history record cumula-

TABLE III

ANNUAL WHOOPING COUGH RATES PER 1,000 OBSERVED IN SPECIFIED SURVEYS

	1. Local Surveys			2. General Survey, Costs of Medical Care				
	Cattaraugus	*Hagerstown*	*Syracuse*	*Rural*	*Villages and Towns Less Than 5,000*	*Towns and Cities 5,000–100,000*	*Cities 100,000+*	*All Communities*
Crude Rates All Ages	18.9	22.6	12.2	21.1	21.4	21.2	16.5	19.6
Crude Rates Under 20 Years	45.8	52.3	32.9	38.8	41.1	40.1	35.2	38.4
Standardized Rates * All Ages	18.1	18.9	12.9	15.0	13.9	13.2	11.4	13.1
Standardized Rates * Under 20 Years	43.8	48.0	32.8	36.7	34.9	32.5	29.2	32.8
Rates Under 20 Years from History Record Cumulation	40.5	40.0	33.7	37.5	35.7	35.0	31.5	34.5

* Standardization by age to white population of the United States, 1930 Census. Standardizing the general survey rates alters them more markedly than it changes the local survey rates, because the general survey populations were composed of families with 2 or more persons, and therefore contained relatively more children than the general population of the local surveys.

tion" in Table III, no decline in the curve is assumed to occur.

The second method of measuring incidence by the morbidity survey method is that of recording the attacks which actually occurred during the course of the survey. The current incidence in the 3 local surveys and in the Costs of Medical Care study by size of community, as well as the rates under 20 years of age, are shown in Table III. The crude rates are not entirely comparable owing to the varying proportions of individuals in the younger age groups, but it will be noted that the incidence in all but the very largest communities is surprisingly close to 20 per 1,000 for all ages and very close to 40 per 1,000 for ages under 20 years.

Based as they are upon person-years of observation, the figures in Table III are average annual rates and so may be considered as showing the expectancy for whooping cough in the respective communities. However, the local survey periods were relatively short, 36 months for Cattaraugus, 28 months for Hagerstown, and 18 months for Syracuse. It would appear that such periods are not very suitable for the calculation of expectancy because in Hagerstown 2 epidemic periods and only 1 inter-epidemic interval were included in the survey period, so that the rates are rather high. In Syracuse, the rates are possibly somewhat low. In the Costs of Medical Care survey, the period of observation in any given locality was only 1 year, but the distribution of the individual community surveys over a period of years and over a wide geographic range yields a much more nearly true mean rate. However, some care may be necessary in interpreting the crude rates of the general survey because only families of 2 or more were included and because some of the cases not having medical attention have apparently not been recorded. These two factors, one tending to raise the rates and the other to depress them, seem to some extent to have offset one another, for the crude rates of the general survey do not differ widely from those in the local studies.

It is evident that the inverse relationship between size of community and incidence, surmised in the discussion of cumulated history curves, does not appear in the crude rates except in the case of the largest com-

munities. It does, however, appear when the rates are standardized for age. The gradient is most characteristic in the standardized rates of the general survey, the incidence in the local surveys being somewhat irregular for reasons explained above.

The rates under 20 years of age obtained by the method outlined under the discussion on history of prior attack are also given in Table II. Although these are not directly comparable to the other types of rate, they do demonstrate the declining incidence with increasing size of community just as do the standardized rates.

The standardized rate of 13.1 per 1,000 for the Costs of Medical Care survey is the most suitable figure for calculating an expectancy for large areas of the United States. When this is applied to the average white population of the registration area in 1929 and 1930, a total of 1,357,000 cases is obtained. This is a somewhat more accurate figure than the expectancy calculated from the case fatality and deaths, but it should be remembered that it is still a minimal one.

AGE INCIDENCE

The whooping cough rates that were observed in each survey are presented in somewhat more detail as regards age in Table IV.

That whooping cough in common with many other infectious diseases of childhood has an older age incidence in rural than in urban areas has long been known. Because the incidence of whooping cough may have varied somewhat in the various communities, as explained above, the ratio of the rates at specified ages to the gross rates under 20 years of age for the respective surveys is used as the basis of the comparison portrayed graphically in Figure IV for the local surveys, and

* Rural: Does not include incorporated villages, however small.

† The case totals of the general survey include a small proportion of cases in persons who were observed less than the full 12 months, but more than 7 months. As the "part-time" population was also used in obtaining the rates, the latter are not materially affected, but these case totals will not agree with those of studies based upon the "full-time" population only.

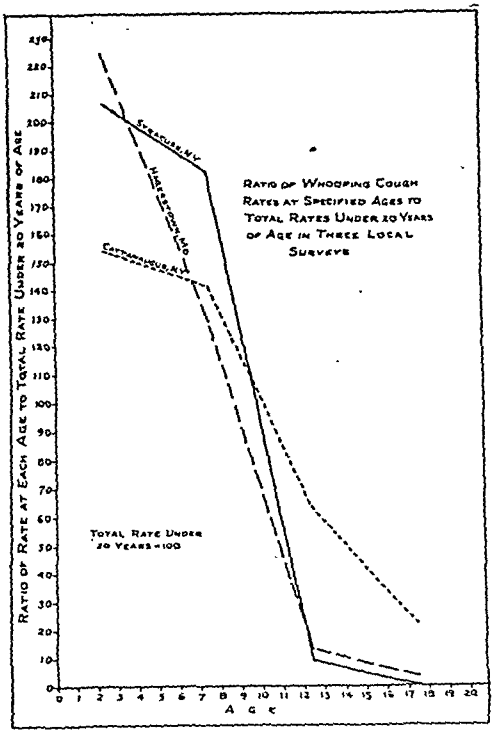

FIGURE IV

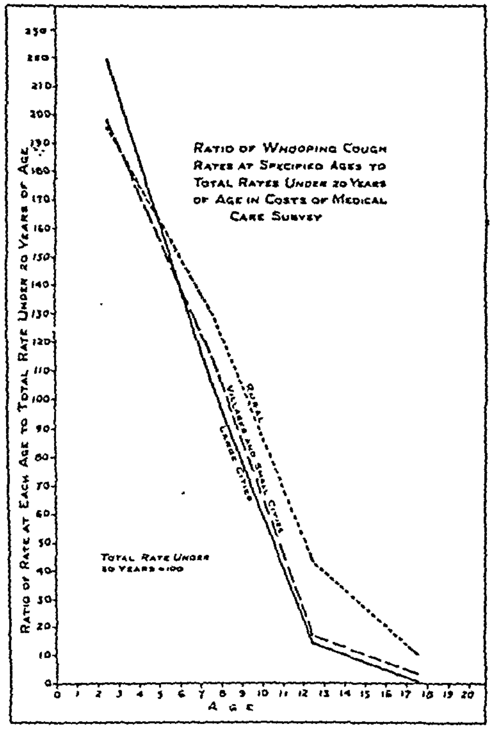

FIGURE V

in Figure V for the Costs of Medical Care study. Possibly the emphasis placed upon families in the general survey has tended to obscure the differences related to size of community, but it will be seen on the whole that the smaller communities tend to have lower rates at the younger ages and higher ones at later ages than do the larger communities.

These differences begin to appear even in small villages as contrasted with farm populations. This is shown in Figure VI, where the respective age-specific ratios of the Cattaraugus survey are compared.

SEX INCIDENCE

The official mortality registration data of many countries show a somewhat higher whooping cough mortality for females than for males at most of the ages of life. This excess mortality in females has long been recognized as a peculiarity of the disease and was at first considered to be due to anatomical differences between the sexes. Of late, however, the tendency has been to find an explanation, at least in part, on the

† Rates based upon a very limited number of cases

basis of a higher incidence of the disease among females.* To such an explanation the figures based upon reported cases give a certain amount of support, but data from the various surveys are not entirely confirmatory.

Table V shows the ratio of female to male rates at specified ages for the 3 local surveys and for the major divisions of the Costs of Medical Care study. The only differences which appear constantly here are: (1) a female preponderance in the youngest age-group in small centers of population as contrasted with a very nearly equal incidence or a male preponderance in cities; (2) a tendency to female preponderance after age 15 or 20, a phenomenon which appears in many of the infectious diseases and is probably due to forces other than increased susceptibility.

SUMMARY

The report deals with the case fatality and incidence of whooping cough in various types of population and with technics of obtaining more reliable incidence figures by morbidity survey methods.

The case fatality of whooping cough was found to be extremely low in the surveyed populations, approximately 0.36 per cent.

Of the 3 sources of information on whooping cough prevalence—reporting, recording histories of prior attack, and recording observed attacks—the paper deals only with the last 2, because of the unreliability of reported totals.

The use of history data in the study of incidence is outlined, comparisons made with such data obtained in various localities, and the tentative conclusion reached that whooping cough incidence varied inversely with the size of the community. Further evidence was found for this in the whooping cough rates observed during the period of the respective surveys.

The age-specific rates under age 20 vary with the size of the community, the larger cities showing higher rates among young children and lower rates in older children than the village and farm populations do.

Finally, few outstanding and consistent differences were noted in the incidence of whooping cough among males and among females in the younger ages of life.

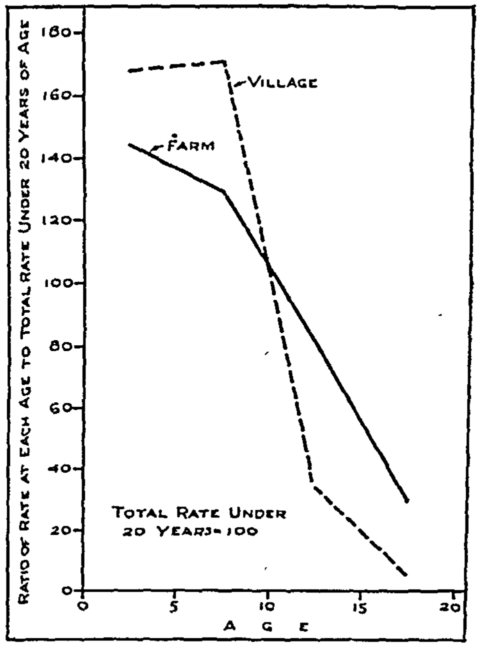

FIGURE VI—Ratio of whooping cough rates at specified ages to total rates under 20 years of age for village and farm populations, Cattaraugus, 1929–1932

* A careful discussion of this question of case incidence and mortality in the sexes will be found in a paper by A. Bradford Hill, entitled "Some Aspects of the Mortality from Whooping Cough," in the *Journal of the Royal Statistical Society*, xcvi, part II, p. 250 ff.

For an Amended S. 5

SPEAKING for twelve organizations of women, Alice L. Edwards, Executive Secretary of the American Home Economics Association and chairman of a special legislative committee representing the organizations, endorses—with certain stipulations—the embattled S. 5 (the Copeland Bill) designed to regulate sales of food, drugs, and cosmetics.

Besides the Home Economics Association, the groups for which Miss Edwards speaks are: the American Association of University Women, the American Dietetic Association, the American Nurses' Association, the Girls' Friendly Society, the Medical Women's National Association, the National Board of the Y.W.C.A., the National Congress of Parents and Teachers, The National Council of Jewish Women, the National League of Women Voters, the National Women's Trade Union League, and the Women's Homeopathic Medical Fraternity.

We earnestly desire the passage of an amended S. 5.

We consider that it is essential that the seizure provision be changed to conform to the present practice. Of course, this change would include the deletion of the provision that makes it possible for the claimant to require that all trials in connection with seizures of his product be held in the court in the district where he resides.

The so-called variations clause should be so amended as to require that a drug product varying from the standard set forth in official compendiums be labeled to indicate in what way it varies.

We also consider it extremely important that the enforcement of the advertising provisions be left in the hands of the Food and Drug Administration, instead of being transferred to the Federal Trade Commission as is urged by certain drug and cosmetic manufacturers.

We consider it highly desirable that everything possible be done to bring about the enactment of a properly amended S. 5 during the present session of Congress.

We know that Congressmen are receiving many letters from their consumer constituents, urging the enactment of a suitable bill for the consumers' protection. We appreciate the fact that many commercial groups that formerly opposed this legislation now have withdrawn their opposition. We wish that more of them might become energetic supporters, aiding consumers in obtaining the enactment of a bill fair to producers, distributors, and consumers alike. We feel that enactment of such legislation would be of advantage, not alone to consumers, but to all reputable manufacturers and would, of course, set the stage for the renewal of consumer confidence in advertising.—

Printers' Ink, Apr. 9, 1936.

Dermatitis from Synthetic Resins and Waxes*

LOUIS SCHWARTZ, M.D., F.A.P.H.A.

Senior Surgeon, U. S. Public Health Service, New York, N. Y.

DERMATITIS in the manufacture of natural resins and from their use has been reported by numerous observers,[1] but dermatitis in the manufacture of synthetic resins and from their use has not been frequently reported [2] or studied.

The principal synthetic resins manufactured in the United States are:

1. Phenol-formaldehyde resins, sold under various trade names, such as Bakelite, Durite, Durez, Resinox, Indur, etc.
2. Urea-formaldehyde resins, sold under trade names such as Beetle, Plaskon, Unite
3. Coumaron resin, made from coal tar residue
4. Ester gums, which are natural resins, such as Rosin, Dammar and Copal, in which the acid of the resin has been combined and neutralized with glycerol
5. The glyptal resins, which are a combination of glycerol and an organic acid, such as phthalic and malleic acids
6. The vinyl resins, which are vinyl esters, ethers or halides combined with phenol, formaldehyde and hexamethylenetetramine
7. Furfural resins, obtained from combining furfural with phenol (furfural obtained from corn cobs by treating with H_2SO_4 and fractional distillation)
8. Chlorinated resins, obtained by chlorinating various oils and balsams
9. Chlorinated waxes, obtained by chlorinating mineral oils, paraffin, naphthalene, di-phenyl, etc.

These resins are used for many purposes:

For making plastics, such as telephone receivers, pipe stems, push buttons, ear phones, cigar holders, bottle caps, buttons, inks, artificial teeth plates, ornaments, bracelets, earrings.

For making varnishes, flexible coatings, floor finishes.

For making cements, wall boards, gears, dishes, water containers, insulators, rubber compounds, and numerous other objects and for electrical insulations on condensers and wires.

The most important of the resins, from a standpoint of volume used and skin hazards, are the phenol-formaldehyde, the urea-formaldehyde and the coumaron resins.

PHENOL-FORMALDEHYDE RESINS

These are made in two principal varieties:

1. The cast resin, which is finished in the factory
2. The molding resin, which is sold to molding companies and completed in the molding process

Phenol or cresol, formaldehyde and ammonia are mixed in proper proportions in a kettle and heated a sufficient length of time and to the proper temperature.[3] They combine and are drawn out of the kettle in the form of a syrup. This is run into pans and allowed to cool, when it solidifies. This is known as "first stage resin," or "alpha resin." The pans are then heated, the resin re-melted and poured into suitable molds. These are placed in large, mineral oil filled carriers and

---

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

placed into *curing* ovens, where they are heated and go through the so-called beta and gamma stages into the completed cast resin.

After being taken out of the oven, the resin is taken out of the molds and oil, and washed with soap and water and dried, and it is then ready to be carved or lathed or bored into whatever object is desired.

During the course of these operations, formaldehyde is given off and the air of the room is strong with the odor of it, unless adequate forced ventilation is employed. Workers in the rooms who are sensitive to formaldehyde may develop dermatitis of the face, neck, and arms, as well as of the covered parts where there is friction, such as the belt line, the ankle at the shoe top, and the wrist at the cuff line.

The oil used in the curing process dissolves out of the resin some of the phenol and formaldehyde and, if used over and over again, it can contain considerable quantities of these substances. One sample which was analyzed after it came out of the ovens contained 2 per cent each of phenol and formaldehyde. The men handling this oil have their clothes splashed with it and at times suffer not only from oil acne and dermatitis of the legs, thighs, and other parts touched by the oil-soaked clothing, but also from dermatitis due to the irritating action of the phenol and the formaldehyde contained in the oil. The eruption in these cases is usually a diffuse erythematous base on which there are scattered the papules and pustules of an oil folliculitis.

The girls washing the oil off the resin, with soap and water, may also develop dermatitis of the hands and arms from the oil and also from the strong soap solution with which their hands are constantly wet. In many factories, the oil is treated with sodium hydrate after each baking in order to neutralize the phenol and formaldehyde it may contain, but if this is not carefully done, dermatitis may result from too much alkali.

The skin hazards to the users of these cast resins are practically nil, because when they are finished no phenol or formaldehyde are given off from them.

The molding resin is made up in numerous qualities, containing different proportions of phenol and formaldehyde and ammonia. It is carried to the alpha stage or beta stage, and then is ground, heated, and mixed with ground wood, zinc stearate, soap, dyes, and hexamethylenetetramine in a mix mill. From this mill it is discharged on to conveyors, where it is air cooled. While cooling, it forms lumps which are ground in mills to proper sizes fit for molding. The workers engaged in mixing, grinding, and packing the molding resin are all exposed to the dust of the irritating chemicals it contains, as well as to the formaldehyde which it gives off, the odor of which permeates the rooms. Dermatitis is a frequent occurrence in this occupation, especially if the rooms are not properly ventilated to draw off dust, and if the machines and jobs where there is dust are not properly protected by suction hoods.

In a factory employing about 400 workers, where no great care was taken to allay and prevent dust, 27 cases of dermatitis occurred in 8 months. Patch tests performed on 10 cases with various resins, hexa, 4 per cent solution of formaldehyde, and 2 per cent solution of phenol, showed that hypersensitivity to hexamethylenetetramine and to formaldehyde was the cause of 80 per cent of the occupational dermatitis in this plant. Hypersensitivity to phenol was also found, but in lesser degree than to formaldehyde and hexa.

The actual cause of dermatitis from exposure to hexa and formaldehyde is the same. They both finally decompose in the presence of warmth and moisture

into formic acid, which is the real skin irritant.

Dermatitis from the dust of the molding resins usually occurs at the points of friction with the clothing—the wrist, the belt line, the shoe tops and the collar line. It may, however, occur on the covered parts when the dust penetrates the clothing. The skin around the eyelids may also be affected. The eruption consists, usually, of scattered papules and vesicles on an erythematous base.

It gets well if the worker stays away from work, and returns again if he resumes work. In this factory, the dermatitis was more prevalent in the winter because the workers did not take showers in cold weather after their shift, whereas in the summer they were more likely to do so.

UREA-FORMALDEHYDE RESINS

These are made by mixing urea and formaldehyde in a kettle. No heat is required, the reaction generating its own heat. A syrupy liquid results. This is mixed with bleached sulphite pulp, under heat and pressure, and dried in tray dryers. It is then mixed in a ball mill with pigments, zinc stearate, and a small amount of hexamethylenetetramine, about ½ per cent. It is then screened, and is ready for shipment. Minute amounts (fractions of 1 per cent) of other ingredients are added to different brands.

The manufacture of the urea-formaldehyde resins on a commercial scale is more recent than that of the phenol-formaldehyde resins, hence the two factories studied had more modern machinery and safety appliances than the phenol-formaldehyde resin factories. There were adequate ventilation facilities and good facilities for dust prevention. As a result, among 190 employees over a period of over 2 years, there had occurred only 4 cases of dermatitis. They were all due to hypersensitivity to formaldehyde. Two chemists in the experimental laboratory of these plants were hypersensitive to formaldehyde and suffered with dermatitis when exposed to it. One of them exposed his forearm in my presence to the mouth of an open bottle of formalin and almost immediately an erythema developed on the exposed skin.

In a molding plant in Ohio employing about 300 workers, where phenol-formaldehyde and urea-formaldehyde resins are used, 26 cases of dermatitis occurred in the first 10 months of 1934, and in a molding plant in Pennsylvania half of the workers developed dermatitis in the hot months of 1935.

The process of molding is practically the same for all the resins. The powder is placed in a "pill machine" and pressed into proper shapes for the molds. The pills are then placed into the molds where they are subjected to heat and pressure which shapes and hardens them. During the molding process gases are given off from the molds and the odor of formaldehyde is strong in the room and irritates the nose and throat and eyes of those unaccustomed to it.

There is an excess of powder in the molds which flows out during the molding process and is only partially "cured." This is called the "*flash.*" When the molds are opened the flash is cleaned off the molds and filed off the molded object.

Patch tests with the resins with which they worked were performed in the winter on 2 active cases of dermatitis, and 10 workers who had recovered from dermatitis, gave only 2 positive reactions, 1 to the phenol-formaldehyde and 1 to the urea-formaldehyde resin. The examination and history of the 10 cases who had dermatitis but were free of it when the patch tests were made, showed that 2 had dermatophytosis and 1 probably had ptyriasis rosea. It

is probable that a considerable number of the 26 cases reported in 1934 were not of industrial origin.

The same plant was visited in August, 1935. Twelve cases of dermatitis had occurred since the first visit 9 months before. This time 9 workers who had dermatitis during this period were patched with suspected samples of urea-formaldehyde and phenol-formaldehyde resins, as well as with hexamethylenetetramine. Four showed no reactions after 24 hours to any of the 7 patches applied. Five showed positive reactions to one or more of the resins, and of these 5, 3 showed positive reactions to hexamethylenetetramine.

Two of the 4 cases who showed no reaction had eruptions at the time the patches were applied. One was a case of dermatophytosis and the other an eczema which dated back to childhood. The weather was cold (less than 70°) during the period the patches were on, and this may have a bearing on the reactions, because, of the 26 cases reported in 1934, 18 had occurred during periods of hot weather in May, June, July, and August.

There can be little doubt that a considerable percentage of the dermatitis in this plant was of occupational origin.

That hexamethylenetetramine is a major causative factor, is shown by the fact that most of the cases occurred in workers handling the phenol-formaldehyde resin, which contains more of it than does the urea-formaldehyde resin.

Hexa, which was extensively used in the rubber industry as an accelerator and caused dermatitis, has now been almost entirely displaced by other accelerators. It is necessary in certain phenol-formaldehyde molding resins in order to furnish the necessary amount of formaldehyde and ammonia required to go through the gamma stage—or to completion.

In the urea-formaldehyde resin, hexa acts as a stabilizer to prevent the resin from hardening before it is molded.

The ventilating and dust prevention conditions in the molding plants were poor. There were no suction hoods over the molding machines. The suction hood over the "pill machine" was out of order. There was only window ventilation in the workrooms, and wash-ups or showers after work were not compulsory. With proper dust allaying facilities, such as forced ventilation, suction hoods, wet sweeping of floors after each shift, compulsory showers, protective clothing and ointments, the incidence of dermatitis in this plant could be decreased.

Dermatitis may occur in users of molded phenol-formaldehyde and urea-formaldehyde resin wares if the hexa is not all combined. Theoretically, it is all combined in the completed resin, but practically (as in some imperfectly cured pieces or pieces in which there was too much hexa in the molding compound to be completely taken up), there may be a sufficient amount remaining to cause dermatitis in hypersensitive people. The same thing may be true of the phenol, if not completely combined.

Dermatitis has been reported as due to contact with finished resin products, such as dermatitis of the ear from telephone receivers, and of the hands from varnishes.

In order to show that a dermatitis may have been caused by contact with a resin, it must be established that:

1. The dermatitis followed contact with the resin
2. That portion of the skin which came in contact with the resin was first affected
3. A powdered portion of the suspected resin placed on the clear skin near the eruption in the form of a patch test, gives a positive reaction if left on 24–96 hours

To determine the actual chemical in the resin which caused the dermatitis,

the nature and chemical composition of the resin must be determined, and patch tests performed on the patient with each of the chemicals composing the resin in order to determine to which of them the patient is hypersensitive.

The patches of the chemicals should be in such dilutions as will not cause reaction on the normal skin if allowed to remain on for 24 hours.

A 2 per cent aqueous solution of phenol can remain on the normal skin in the form of a patch test, for 24 hours without causing a reaction.

A 4 per cent solution of formaldehyde can remain on the normal skin, in the form of a patch test, for 24 hours without causing a reaction.

Powdered hexamethylenetetramine may remain on the normal skin, in the form of a patch test, for 24 hours without causing a reaction.

Powdered coumaron resin may remain on the normal skin, in the form of a patch test, for 24 hours without causing a reaction.

Coumaron resin is used in varnishes, adhesives, rubber, paint, chewing gum, lacquers, paper and fabric sizing, printing inks, and waterproofing.

It is made from the crude coal tar distillate, which comes off between 150° and 200° C.

This distillate is re-distilled to remove impurities such as benzol, toluol, zylol, naphthalene and tar acids—and a sharply fractionated naphtha is obtained. The naphtha is dried in lead-lined or stone-ware receptacles by treatment with H_2SO_4, in the proportion of 3 to 5 parts per 1,000. After standing a while, the acid is drawn off and fresh H_2SO_4 is added slowly and agitated until 3 to 5 per cent of acid is added. The kettle is kept cold during the reaction with brine-cooled refrigeration.

After the reaction takes place, the mixture is allowed to stand until the tar and sludge settle. They are then removed and the remaining oil is pumped to a neutralizing tank and treated with caustic soda to destroy the remaining acid. The oil is then washed with water to remove the soluble matter, and it is allowed again to settle and the water is removed.

The oil is now distilled and the solvent naphtha is distilled off and the naphthalene is removed by live steam. After this, there remains a heavy oil boiling at 320°–330° C., which is removed from the resin.

COUMARON RESINS

There are no skin hazards, outside of acid and alkali burns, in these operations, because they are totally enclosed. No skin lesions were found in a large plant and the medical records for a number of years showed no cases of dermatitis.

Dermatitis has occurred from coumaron resin in varnish which was used on heddle frames in a cotton mill. The skin on the forearms of the weavers was struck continuously by the moving heddle frames and some developed dermatitis. Patch tests showed that they were sensitive to chlorinated ceresin and coumaron resin in the varnish. The varnish grades of coumaron resin, especially the darker resins, may contain sulphuric acids resulting from the sulphuric acid treatments, if they are not carefully prepared, and it is these acids that cause dermatitis.

SYNTHETIC WAXES

The principal synthetic waxes manufactured in this country are chloro naphthalenes and the chloro diphenyls. They are both used for practically the same purposes—as electric insulators on condensers, as insulators on electric wires, in paints, varnishes, and lacquers, and as oil in transformers.

The chlorinated naphthalenes are made by passing chlorine through

naphthalene and replacing of the hydrogen atoms with chlorine. One or more of the hydrogen atoms can be replaced, forming mono, di, tri, up to per chloro naphthalene, in which 8 of the hydrogen atoms are replaced with chlorine, the formula being $C_{10}Cl_8$. The more chlorine, the more solid is the material.

In making chlorinated diphenyls, it is first necessary to manufacture diphenyl, $C_{12}H_{10}$. This is manufactured by passing benzol, C_6H_6, through molten lead, at a temperature of about 800° F., where 2 molecules of benzol combine to form 1 molecule of diphenyl, hydrogen being set free.

Diphenyl is a solid, crystalline-like substance. This is melted in closed cylinders and chlorine is bubbled through, replacing the hydrogen. One or more of the hydrogen atoms can be replaced, forming mono chloro diphenyl, di chloro diphenyl, up to deca chloro diphenyl, $C_{12}Cl_{10}$. Hydrochloric acid is a by-product of this reaction. The chloro diphenyls are liquid or semi-solid, up to the hexa chloro diphenyl.

Nonochloro diphenyl, $C_{12}HCl_9$, sold under the trade name of Arachlor, is used as an insulator for automobile electric wires and in condensers, and also as a de-lusterer of rayon.

In the manufacture of the chloro diphenyls, the workers are exposed to a benzol hazard when the diphenyl is made, as well as to a hazard from the inhalation of the fumes of diphenyl.

The workers engaged in chlorinating the diphenyl, especially that part of the operation where the crude Arachlor is being re-distilled to remove impurities, are affected with an acne-like condition of the skin. This also occurs in workers exposed to the fumes of the chloro naphthalenes, or Halowax. The fumes of these compounds cause acne on the face and neck and may penetrate the clothes and cause acne-like lesions to develop on the covered parts, the shoulders, and the belt-line, and even on the penis. The lesions on the skin resemble acne. They begin as small, pale, elevated papules, many *having no openings in them.* They develop into hard cyst-like elevations under the skin, some of which go on to suppuration, forming boils. Some of the lesions also occur at the mouth of the follicles and resemble the comedones and pustules of acne vulgaris.

In addition to these skin lesions, symptoms of systemic poisoning have occurred among workers inhaling these fumes. Those working with the chloro diphenyls have complained of digestive disturbances, burning of the eyes, impotence and hematuria. The latter symptom developed among a number of men making amino diphenyl, which is used in the manufacture of a rubber antioxidant. Cases of death from yellow atrophy of the liver have been reported among workers exposed to the fumes of the chloro naphthalenes.

Patch tests performed with Halowax and with the chloro diphenyls have yielded negative results. The skin lesions probably result from the mechanical plugging up of the follicles of the skin with the waxes as the fumes solidify on the skin.* The chlorine present in the waxes may have an irritating effect on the plugged follicles and cause suppuration.

PREVENTION

1. The protection of the workers from the irritating chemicals that compose the resins and waxes from the resins and waxes themselves. To do this, the process should be totally enclosed. If this is not possible, hoods with suction exhaust should be so placed over open processes that dust and fumes are pulled away from the worker and out of the room.

* I have recently seen the wife and child of a worker who had developed comedones and pustules from contact with his work clothes which were saturated with halowax and which he was accustomed to wear at home. L. S.

2. The workrooms themselves should be ventilated by intake and exhaust fans to remove dust and fumes.

3. The floors, walls, and ceilings should be washed down at frequent intervals to keep them free of dust.

4. Two lockers should be furnished to each worker. One for his street clothes and one for his work clothes. The lockers for street clothes and work clothes should be in separate rooms, with the shower baths between the locker rooms. The worker coming to work enters the locker room for the street clothes, takes them off, and puts them in the locker and goes into the locker room where his clothes are kept and dons them. From this room he goes to the workrooms through a connecting door. At the end of his shift, he goes through this door to the work clothes locker room, takes off his work clothes and leaves them on the floor or bench to be washed and then goes to the shower baths and bathes and dries. Then he goes to the street clothes locker room, puts on his clothes and goes out of the door leading to the street. It has been estimated at one plant where such a system was instituted that 6 cents a day per worker will take care of furnishing clean work clothes each day.

5. New workers who are hypersensitive, but have only mild eruptions, should be given protective ointments and clothing and kept at work for about 3 or 4 weeks with the hope that they will develop an immunity or become "hardened." If this does not occur, they should be taken off the job.

6. New applicants for jobs should be carefully examined for skin diseases and those found to have them should not be employed.

7. There should be periodic medical examination of workers to detect cases of dermatitis and workers in chlorinated naphthalenes and diphenyls should be periodically examined for symptoms of systemic poisoning.

8. Laws should be passed making it compulsory for factories where there are skin hazards to adopt these measures.

A. I. C. P. Guide for Public Health Nurses

A *GUIDE for Public Health Nurses* published by the New York City Association for Improving the Condition of the Poor, is a unique publication. A systematic description of cardiac conditions, for the benefit of public health nurses and a guide to the care which they can give patients has recently been prepared by the Bureau of Educational Nursing and has been subjected to the criticism of outstanding cardiologists.

Similar guides covering syphilis, child development, and tuberculosis have recently been revised and, although intended for the nursing staff of the A.I.C.P., they will readily be of interest to a wider circle.

Set-Up and Budget for Public Health Education*

IRA V. HISCOCK, F.A.P.H.A. (*Life Member*)
Professor of Public Health, Yale School of Medicine, New Haven, Conn.

MODERN public health practice has shown how to prevent much unnecessary sickness and premature death and how to maintain and promote personal and public health. How can the necessary factual information be brought to public attention in such a manner as to produce action? Able direction of a well organized and financially supported health education program for the state and local areas is essential. The major purposes are: to make health information public by technics which arouse, stimulate, and guide motives for healthful living; to provide the members of a community with an understanding of the functions and services of a health organization, of the community responsibilities for public health work, and of the opportunities of individuals and groups to insure adequate support of essential public health services.

There is no single formula for a "set-up and budget" for public health education. Conditions vary enormously in different communities or localities. Certain basic principles have been developed which are subject to review periodically as new discoveries are made or new technics are found practical. The importance of periodic evaluation of health education programs is becoming increasingly recognized, but methods of evaluation have been only partially developed.

RESPONSIBILITY AND TEAM WORK

A comprehensive health education program embraces at least 3 closely related phases: (1) popular health instruction, (2) health education for professional groups, and (3) school health education. To fulfil the obligations of this threefold program, and to provide opportunity for coöperative study and future planning, the various features may well be correlated and developed through a public health education council. Such a council may be formally organized as an independent group or as a part of a community health council, or it may merely take the form of informal conferences of representatives of the community agencies interested in health education.

The ultimate responsibility for community health education rests with the health officer or someone selected by him who has experience and training for the task. Even though health education work in schools is the major responsibility of the education authorities, the health officer should supply current information regarding health conditions, and aid in the provision of available services for health education of teachers and pupils. The state department of health likewise has a responsibility to serve as an advisory and

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

correlating force, and to provide some basic tools for health education work. In addition, the state department can pass on to the local communities the valuable materials and methods developed by national health agencies.

CLARITY IN PLANNING

Bertrand Brown has defined 4 basic tasks in health education which are applicable to the 3 phases of a health education program. These are indicated by the 4-part question: (a) What ideas, images, and emotional appeals must be conceived, accumulated, arranged, set forth, and produced; (b) transmitted through what medium, or by what means; (c) to what audiences, in what locality or localities; (d) to accomplish what objectives?

In order to plan health education work intelligently, and to pursue it economically and effectively, each of these 4 fundamental tasks, closely related, needs consideration.

OBJECTIVES BASED ON STUDY

Advance preparation of a carefully considered program is essential to good work. The basis for program making is a study of the situation to determine the major factors involved, the public response desired, and the necessary procedures. The objectives should then be definite and reasonable. For example, the health officer should have clearly in mind what he wishes the people to do as the result of health advice. The final test of health education is not how much information is distributed, but how behavior is influenced. The objectives should have importance locally and be attainable with the facilities at hand. The technic of gaining public attention and of producing action is an art and a science, requiring a knowledge of human motivation, of human interests, and of human actions.

COMMUNITY PARTICIPATION

Having studied the community, the next steps are the enlistment of community forces, the selection of subject matter, and the development or utilization of technics of application of various methods. Methods should be selected for reasons of economy—with a view to reaching the largest numbers effectively at the smallest expense; for attention value, to reach persons under conditions which are favorable to secure attention; and for their suitability to the subject matter. For example, some topics lend themselves to exhibits, others to the newspaper, others to classroom projects.

The selection of material to be presented to the public, including professional and school groups, will depend upon local circumstances. In addition to general health information which is aimed to build up a better public understanding, advice may be given regarding specific problems such as special disease hazards or the pressure of nursing services. An understanding of problems and opportunities is necessary to bring about intelligent action regarding the maintenance of qualified personnel and an adequate budget.

There are several important groups to be kept informed for whom the objectives and methods vary. These groups include: (a) responsible citizens, (b) public officials, (c) medical and related groups (doctors, dentists, nurses, hospital staffs, veterinarians), (d) recreation and social workers, (e) school teachers, (f) clergy, (g) children (schools, 4H clubs, etc.), and (h) the general public.

In considering the set-up necessary for health education work, attention must be given to the methods which are suitable for each group to be reached. Too little has been done with the prominent citizens, business and club leaders, and public officials, whose un-

derstanding of the opportunities and services is necessary to insure support of public health activities. Through these groups may be developed informed public opinion, aid in specific matters of program and budget, and channels of sound information regarding public health within a community. Methods which may be used include personal contacts of health personnel, health talks, committee participation, exhibits, motion pictures, distribution of annual reports, periodic bulletins, pamphlets or special books on health subjects, and press releases.

With medical and related groups, a primary objective is to secure improved and wider utilization of preventive medical services. The advice and assistance of these bodies are fundamental for success.* As with the school teachers, the clergy, welfare workers, and other professional groups, the individuals must be kept informed to enable them to discuss and interpret effectively the work of health organizations. For the broad community phase of the program, there must be staff talent to prepare or to secure attractive and authentic printed material of various kinds, and to stimulate volunteer leadership and participation.

As defined by the fourth health education institute, the school health program aims to establish habits, practices, and attitudes toward health which will carry over into adult life and enable the individual to function as a healthy person. A division of school health education, built around a supervisor for a county or city, and a director for a state, the work being correlated with the health department and other health agencies, is an essential factor in the development of a well rounded community program. To enlist community participation, then, a well conceived educational program must be based on material of accurate fact, properly interpreted. A calendar of projects for the year, somewhat flexible, is a useful guide.

PERSONNEL AND BUDGET

For many years there has been much study and experimentation in public health education. The organization of an effective program in a community depends in no small degree upon the resources of the health department and the initiative and ability of the health officer. In the smaller communities, popular health instruction work may be entirely directed by the health officer, who may utilize civic and professional groups for assistance and advice. The school health education services may be supervised and coördinated by a well trained worker with educational background and organization ability serving on a county-wide basis, and working closely with both the education and health organizations of the county and state.

In cities of 100,000 population or over, the health officer will need the assistance of a popular health instruction director or supervisor, with a staff suitable for the size of the community. This person should understand the facts to be given to the public, have organization ability and newspaper sense, be familiar with the useful free material available, and be able to utilize statistics and other source data in a practical manner. Most of the budget for this work will be for salaries, including stenographic service, with a reasonable allotment for materials. Except in the largest cities, most of the printed material and exhibits will be obtained from sources other than the local health department.

From 2 to 3 per cent of the total public health budget (4 to 6 cents per capita per year) would seem to be a

* Medical associations are helping in constructive programs of health education in many localities. The American Medical Association, through a special division, and national health agencies are rendering valuable service.

reasonable amount to set aside for the purpose of popular health instruction in addition to the provision of a division of school health education. The latter may be so organized that the supervisor is the liaison officer on health affairs between the school and other community health agencies, as well as the nucleus around which health work in the schools may be developed. Here again, most of the specialized budget will be for the salary item. As the principals and teachers become more and more familiar with public and personal health principles, they can assume increasing responsibility for many details of health education to be furthered in the regular curriculum.

State departments of health have been gradually adding public health education divisions or services to the administrative organizations with beneficial results. In 1930, the proportion of the health department appropriation in 11 states varied from 0.5 per cent to 7 per cent, with a median of 2.2 per cent. Twenty-five states in that year conducted this work in the executive or central administrative office. There is a growing tendency on the part of state departments of health to form some type of liaison arrangement with the educational authorities whereby improved courses in hygiene are incorporated into the educational system. There is also a growing tendency to use the educational system for the promotion of general health education work. Increasing attention to the health aspects of the school program given by teachers colleges and boards of education should provide increased personnel resources, and may gradually modify existing programs of both the school and community health departments as they relate to health education.

Public health education is a relatively young and rapidly developing field of public health activity. There is yet much pioneering and discriminating study to be done. Emphasis is properly being given to the psychological aspects of the problem and to many other related subjects. Patience, perseverance, and confidence in the ultimate possibilities are required of the workers to provide a stable program, properly integrated with the other essential features of community health work.

Bullock County, Ala.

IN connection with the Rural Health Conservation Contest a rather unusual activity for Chamber of Commerce Health Committees was recently undertaken by the Health Contest Committee of Bullock County, Ala., of which committee Judge W. E. McNair is Chairman. The committee undertook the publication of a 12 page bulletin on Good Health, containing vital statistics data, information on the use of Burr cottages for the care of tuberculosis cases, with general control measures, sanitary type of privies, rodent control, mosquito control, rabies control, and with special data on the health activities of the county schools and the county health department.

Veterinary Service in the Control of Dairy Products*

JOHN G. HARDENBERGH, V.M.D.,
Director of Laboratories, The Walker-Gordon Laboratory Company, Inc., Plainsboro, N. J.

IN terms of human welfare, milk and milk derivatives affect more generally and more closely the daily lives of men, women, and children in this country than any other food product. As a corollary, the relation of veterinary science to public health is best exemplified in the veterinary aspects of milk control. The story of safe milk as a factor in promoting human health has been signalized, dramatized, and advertised, but the consuming population is only partly conscious of the affiliation between the medical sciences, their correlated activities, and the wholesomeness of the dairy products made available.

The tremendous progress made in the development of safe milk supplies and the part played by safe milk in improving our health status make an absorbing story. It is a story of research and observation, of putting to work facts revealed by patient research, and finally of practical application of accumulated knowledge and experience to the everyday problems of milk production and distribution. It is a story to which many branches of science, the professional health worker, and the dairy industry itself, have contributed about equally.

The scope of this paper is a discussion of veterinary science and veterinary service in the control of dairy products. Recognition of the fact that certain infectious diseases of cattle are transmissible to man through milk, also that some less specific conditions, particularly of the lactating udders of cattle, may render milk unwholesome for human use, has served to focus attention upon a fundamental of pure milk, namely, the health of dairy cattle. These facts, along with the problem of human disease transmissible through milk, have necessitated the development and interposition (between the producing animal and the consumer) of protective measures, especially pasteurization, in order that the general market milk supply may be adequately safeguarded.

VETERINARIANS AND THEIR GENERAL ACTIVITIES

In reviewing the veterinary aspects of milk control, the outstanding contribution which the profession has made to the creation and development of safe milk supplies is seen in the control of bovine diseases by private and organized veterinary agencies. In order to visualize how these activities have been and are carried on, a bird's-eye view of the veterinary profession as it exists in this country will be helpful.

A survey[1] made a few years ago by

---

* Read before the Laboratory Section at the Sixty-fourth Annual Meeting of the American Public Health Association in Milwaukee, Wis., October 10, 1935.

the Committee on Education of the American Veterinary Medical Association showed that there are between 12,000 and 13,000 graduate, registered veterinarians in the United States, of whom about 9,400, or roughly 75 per cent, are engaged in private practice (Table I). In animal disease control, the practising veterinarian serves as the first line of defense as does the practising physician in human disease control. Of the remaining 3,000 to 4,000 veterinarians, about 1,400, or a little less than 12 per cent, are engaged in U. S. Bureau of Animal Industry and other federal work, and about 700, or a little more than 5 per cent, in state bureaus of animal industry. About 1,000 veterinarians are engaged in teaching, commercial, municipal, and army activities.

TABLE I

LINES OF WORK ENGAGED IN BY VETERINARIANS [1]

	Number	Per Cent
Practice	9,359	76.5
Army	126	1.0
Bureau of Animal Industry (Federal)	1,353	11.1
Other Federal Work	60	0.5
State	660	5.3
Teaching	230	1.9
Commercial	250	2.0
Municipal	202	1.7
Totals	12,240	100.0

The survey, which represented a very complete analysis of the veterinary situation from the educational and professional standpoints, also indicated the average distribution of time given to various species by a representative group of practising veterinarians (Table II).

It is significant in connection with our consideration of dairy products that the modern practising veterinarian gives, on the average, more of his time to cattle than to any other species.

There are a number of activities re-

TABLE II

DISTRIBUTION OF TIME GIVEN TO EACH SPECIES BY PRACTISING VETERINARIANS [1]

	Per Cent
Cattle	38.0
Pets	23.9
Horses	18.5
Swine	14.1
Poultry	3.0
Sheep	2.3

lating to milk control which require either the employment of veterinary personnel or the coöperation of agencies whose professional staff is composed principally of veterinarians. Chief among these are:

1. *Control and eradication of bovine disease under official supervision*—This work is carried on and participated in by (1) the U. S. Bureau of Animal Industry working coöperatively with (2) state bureaus of animal industry, or state livestock sanitary boards; these agencies employ in addition to their full-time veterinary personnel (3) many practising veterinarians on a part-time basis.

2. *Milk and dairy inspection under official supervision*—This work is participated in by: (1) veterinarians employed full-time by state and municipal departments of health or other agencies charged with regulation of milk supplies; and (2) practising veterinarians authorized to make dairy herd examinations.

3. *Milk and dairy inspection work carried on by producer and distributor organizations*—This work is voluntary and relates principally to milk quality improvement and disease control, principally of mastitis, among dairy herds. It is carried on by veterinarians employed full- or part-time by commercial milk organizations to do field inspection and educational work with milk producers. It is an important adjunct in many areas to the official milk inspection program.

There are other ways in which veterinary activities are correlated with dairy products control but these are of major importance.

1. Control of Bovine Diseases and Safe Milk

The safety of milk is determined chiefly by 4 factors: (1) the health of dairy cattle, (2) the health of dairy employees, (3) methods of producing and handling milk to prevent contamination, and (4) the additional protection—effective pasteurization—which is necessary in order that the general market milk supply may be adequately safeguarded. It is conceded that healthy dairy herds are a fundamental without which the development of our milk supplies to meet consumer needs would be extremely unsound and unstable.

We have a vast fund of information on the origin and nature of diseases of the dairy cow; on methods of diagnosis and methods of identifying the causative organisms; on the communicability of certain of the diseases to other animals and to man; on methods of control and eradication. Most of this has come to us in the last 4 decades as the result of research which now forms the basis for nation-wide programs of disease control among dairy cattle. Sufficient of this knowledge has been applied on a scale which not only enables us to foresee the future but also to view in retrospect the accomplishments to date.

BOVINE TUBERCULOSIS

Bovine tuberculosis is the best example of an animal disease communicable to man which may soon cease to exist here as a danger to human or animal health. The story of bovine tuberculosis and its relation to human health—particularly child health—has been told too often to require repetition. We should be equally familiar with the federal-state program for elimination of bovine tuberculosis that has been under way since 1917.

The first tuberculin test of dairy cattle was conducted in this country in 1892. Thereafter it was applied to ever-increasing numbers of cattle by private veterinarians and the state and federal bureaus of animal industry. As a group, certified milk herds were the first to require regular tuberculin tests; this was done shortly after the introduction of tuberculin as a diagnostic agent. In 1917, the movement received its first real impetus when the federal-state coöperative program embodying the uniform accredited-herd plan was adopted and provision made for payment of indemnities for slaughtered tuberculous cattle. This work proved very successful and was made still more effective in 1923 when the area plan of tuberculin testing was put into effect.

In the 19 years from 1917 to 1935, more than 150 million tuberculin tests were made on cattle and about 3¼ million reactors removed from the herds and slaughtered. As a result, on May 1, 1935, 2,237 counties, or 72.8 per cent of the 3,071 in the United States, were classed as modified accredited areas (areas in which there is less than 0.5 per cent bovine tuberculosis). Twenty-five whole states are now designated as modified accredited areas (Arkansas, Colorado, Florida, Idaho, Illinois, Indiana, Kansas, Kentucky, Maine, Michigan, Minnesota, Missouri, Nevada, New Hampshire, New Mexico, North Carolina, North Dakota, Ohio, Oregon, Utah, Virginia, West Virginia, Washington, Wisconsin and Wyoming).

Perhaps many of us are not aware of the marked effect which this work has had upon the human death rate from tuberculosis. State and city health officials have vigorously backed up the tuberculin testing program of

TABLE III

DEATH RATE FROM TUBERCULOSIS IN THE UNITED STATES

Calendar Year	*Respiratory Tuberculosis*	*Other Forms*	*Cattle Tested Fiscal Year June 30*	*Number Reactors*	*Per Cent Reacting*	*Per Cent Retained*
1900	180.5	21.4

1933			13,073,894	255,096	2.0	0.42
	Totals		115,170,388	2,693,570	2.3	

(Official Statistics compiled by H. R. Smith, Livestock Commissioner, National Livestock Exchange)

The relationship of the number of cattle tested in the United States, the reactors slaughtered, the decline in percentage retained for tuberculosis (lesions found on post-mortem) of all cattle slaughtered, exclusive of reactors, and the decline in the human death rate from respiratory and other forms of tuberculosis per 100,000 population in the United States. The federal and state coöperative testing program started in 1917. This is from data furnished by the U. S. Bureau of Animal Industry and the Division of Vital Statistics, Bureau of the Census.

the state and federal bureaus of animal industry which has resulted in reducing the number of positive reactors in cattle from 4.9 per cent in 1918, to 1.1 per cent for the year ending June 30, 1934. This support has been forthcoming because of evidence such as that given by Park and Krumwiede [2] and others that the bovine tubercle bacillus causes about one-tenth of the bone, joint, and lymph node tuberculosis in adults, and one-fourth of this type of tuberculosis in children. In young children it is said to cause from 6⅓ to 10 per cent of the total fatalities from tuberculosis.

H. R. Smith, Livestock Commissioner of the National Livestock Exchange, has called attention in a con-

vincing manner to the changes in the death rate from tuberculosis in man since 1918. He has compiled official statistics[3] from the U. S. Bureau of Animal Industry relating to tuberculin tests of cattle, percentages of reactors and percentages of other cattle "retained" after slaughter, along with data from the Division of Vital Statistics, Bureau of the Census (Table III). The human death rate from respiratory tuberculosis in the United States in 1918 was 128.6 per 100,000 population, but it has decreased every year since then, and last year was 56.6, or less than half the rate in 1918. During the same time the death rate from tuberculosis other than respiratory declined from 21.4 per 100,000 in 1918, to 5.9 in 1933. It is not claimed that this was due entirely to the coöperative program of the government for the eradication of bovine tuberculosis death rate, but it is significant that during the 18 years prior to 1918 the death rate from tuberculosis other than respiratory did not decline; in fact, the trend was slightly higher: 21.4 per 100,000 in 1900, and 22.5 in 1917, with no fall below the 1900 rate in the intervening years. Commenting on these figures, Smith says:

> According to medical authorities, cases of human tuberculosis other than respiratory such as glandular, bone, and abdominal are to a large extent of bovine origin. The decline in the death rate from respiratory tuberculosis from 1900 to 1918 is probably due to improved sanitation and medical care. It is apparent that this was offset in its affect on other forms of tuberculosis by the increase in this disease in cattle during that period, as indicated by the increased percentage retained. While there was no decline in the death rate from non-respiratory tuberculosis from 1900 to 1917, when the federal and state coöperative cattle testing was started, the decline in the death rate from such types has since been pronounced.

This analysis does not take into account the concurrent effect that increased pasteurization of milk supplies has had since 1918, which is considerable in those states where the process has been rapidly expanded in recent years. The observations of Park in New York City indicate marked reduction in human infections with bovine tubercle bacilli since pasteurization was applied to all milks except certified.

Nevertheless, a greater decline in the bovine type of infection in humans has been noted after the tuberculin test of *all* dairy cattle was required for *all* grades of milk than when pasteurization alone was depended upon for protection. The moral is obvious.

THE USE OF MILK FROM TUBERCULIN TESTED HERDS

As the tuberculosis eradication program has progressed, the number of cities and states which demand milk from tuberculin tested cows has increased rapidly. Within the past year tuberculin testing has proceeded so rapidly that an accurate estimate of the amount of so-called "tuberculin tested" milk cannot be made. However, in the 5 years, 1927–1931 inclusive, the amount of such milk in cities of 10,000 and over increased from 68.1 to 88.7 per cent, or more than 20 per cent. Effective pasteurization will kill bovine tubercle bacilli, but the requirement that dairy herds shall be free from tuberculosis even if the milk is to be pasteurized recognizes the principle that processing methods cannot replace proper standards of health for dairy animals.

The relation of veterinary science to the safeguarding of milk supplies from the menace of bovine tuberculosis has been reviewed at considerable length because it symbolizes what may be done by joint action in surmounting risks to human health. The responsibility for sanitary control of milk supplies rests, as it should, very largely on medical and other professional health officers; the veterinarian serves as the qualified

instrument to carry out measures for animal disease control.

BRUCELLOSIS IN ANIMALS AND MAN

Bang's (abortion) disease is another common infection of dairy cattle caused by an organism sometimes capable of infecting human beings. Brucellosis of man and animals seems of greater current interest to health authorities than bovine tubercle infection. Since a certain proportion of Brucella infections in man is acquired through raw dairy products, the efforts to control the infection in cattle are relevant to any discussion of the veterinary aspects of public health.

Although Bang's disease has been continuously studied since the discovery of the causative organism in 1896, the most intensive efforts to work out methods of control and elimination have been applied during the past decade. The agglutination test is a reliable means of detecting Brucella infected animals. When repeated at suitable intervals by experienced operators, followed by the removal of reactors, the test is a dependable method under favorable circumstances of ridding herds of the infection. Cotton and his associates [4] of the U. S. Bureau of Animal Industry, have shown that the blood-serum test in competent hands gives more reliable information regarding udder infection with *Brucella abortus* than the milk serum test; also, that a blood-serum titer of 1:1,000 nearly always indicates udder infection; at 1:200, about 50 per cent of the animals so reacting have infected udders; at 1:100, cows rarely show infected udders unless they have recently been infected and have not reached their maximum agglutination titer. Repeated tests will detect such animals.

Several other investigators have reported similar observations so that, from the public health viewpoint, it may be concluded that dairy herds effectively maintained free from reactors to the agglutination test at 1:100 or higher, present little, if any, danger of transmitting brucellosis; exceptions are very rare. Not all cases of brucellosis in man are caused by the bovine type of infection or by infected milk, but the number is sufficient to require that adequate protection be given milk consumers. This protection is furnished by removal of all infected cattle from dairy herds, by pasteurization, or by a combination of these methods.

Much more information, especially much better epidemiological evidence, is needed in order to evaluate with accuracy the importance of Bang's disease to human health. Lacking this information, one cannot visualize the extent to which public health and animal health agencies will combine in supporting an elimination or control program against the bovine disease. In the case of bovine tuberculosis, the eradication program received its greatest stimulus and greatest support, both scientific and legal, on account of human health implications. In Bang's disease, the public health aspects are not yet so clearly defined although the economic aspects are quite fully recognized by the livestock industry.

When the health and economic phases of Bang's disease have been more fully appraised, it should be possible to decide whether or not the nation should embark upon a wholesale eradication program as was done with bovine tuberculosis, or work out other control methods, including immunization of dairy animals. In any event, the final responsibility for carrying out whatever measures are adopted will fall very largely on veterinary agencies.

Of interest in the consideration of undulant fever at this time is the federal Bang's disease testing program that has been carried on for over a year as one of the emergency measures

of the Agricultural Adjustment Administration. Originally designed to reduce dairy cattle populations and thereby milk surpluses, the A.A.A. allotted funds to the U. S. Bureau of Animal Industry for disease control work which was broadened to include Bang's disease. The tests have been conducted more or less actively in all but 2 states since July, 1934. The federal government has paid indemnity to the owners of reacting cattle, amounting to not more than $50 each for pure-bred, and from $20 to $25 for grade cattle.

A summary of this work to June 30, 1935, shows that more than 3,300,000 cattle have been tested, of which 381,000 were found to be reactors (complete agglutination in dilution of 1:100 or above). These figures include a considerable number of retests. On initial tests all over the country, the average reactor rate has been 14 per cent of the cattle under supervision. Infection has been found in about 43 per cent of the herds tested.

Funds have been allotted so that this work can be continued to July 1, 1936. It is hoped that many of the dairy herds, under proper supervision, will be maintained free from abortus infection. Some states already have made provision to add to the federal indemnity or to carry on the program after the federal assistance ceases.

The foregoing considerations of bovine tuberculosis and Bang's disease are illustrative of what may be done by veterinary research and veterinary supervision in protecting milk supplies from animal contagions. There are other less common diseases of dairy animals which are kept in check or not permitted to retain a foothold in this country. Foot-and-mouth disease is one of the most highly contagious diseases for cattle; man is somewhat, although not particularly, susceptible to the infection either by direct contact or through drinking infected milk. Children are more susceptible than adults. On the few occasions that foot-and-mouth disease has gained entrance to this country, it has been eradicated as promptly as possible by complete destruction of infected and exposed herds. Thus, through the operation of veterinary police measures, foot-and-mouth disease does not exist in the United States either as an animal disease or public health problem.

2. Official Milk and Dairy Inspection Service

State and city health departments all over the country quite commonly employ veterinary personnel to carry on certain phases of milk control work. In some instances, these veterinary activities are related solely to disease control supervision to see that the local requirements with respect to tuberculin tests, physical examinations, etc., are observed in the dairy herds comprising the milk-shed. In others, the veterinary personnel is charged with all phases of dairy inspection work, covering the herd, the stable, and other physical equipment, and production and handling methods.

3. Industrial Milk and Dairy Inspection Services

One of the prominent characteristics of modern milk supplies has been the development by producer and distributor organizations of their own inspection and control services. The desire of, or the necessity for, commercial organizations to foster quality improvement work is an outgrowth of healthy competition and the increasingly complex official requirements and regulations with which health departments have surrounded milk supplies, particularly in our metropolitan areas. The sum total of the benefits derived in terms of better educated dairymen, healthier herds, better dairy facilities,

and higher quality milk is tremendous. With the aid of these commercial inspection services, the compliance of dairy farmers with local regulations has been greatly facilitated in many instances. Through the field inspection work carried on by milk distributing organizations, the meaning, importance, and necessity of many milk regulations have been translated to milk producers more effectively perhaps than would have been the case otherwise.

Bonuses offered to producers for higher fat, lower bacteria count milk, and for improved dairy facilities have resulted in constantly improved milk supplies. Veterinary field work by distributor organizations has also been extremely helpful in showing the dairy farmers the advantages of tuberculin testing, of mastitis control, and of dairy hygiene and sanitation in general. The grading system with its higher prices for better quality milk has had a salutary effect on those milk sheds where it has operated. Veterinary personnel has been one of the principal media through whcih the programs have been put into operation.

It has been impossible to determine accurately the extent to which veterinarians and veterinary agencies contribute essential services in the control of dairy products. It is certain, however, that a survey would show a long list of activities and accomplishments in addition to those discussed.

Space does not permit more than brief mention of the work already done and to be done in the control of bovine mastitis. This disease certainly occupies front rank among bovine ailments in its effect upon the quality and economic phases of milk production. Its public health implications are less well defined except on the general principle: milk from cows having mastitis, whatever the cause, is not fit for human consumption. This principle necessitates a workable definition of mastitis of a degree significant to public health and milk quality. I shall not attempt the definition but would call attention to the frequent misunderstandings and mis-statements relative to mastitis and the streptococci which are commonly associated with it. The statement, "Milk containing large numbers of mastitis streptococci causes outbreaks of septic sore throat and scarlet fever," is misleading unless it be qualified with the explanation that the infecting organisms in such cases must be human pathogens and not the variety commonly found in bovine mastitis. As Brown has expressed it [5]:

> Streptococcal bovine mastitis is very prevalent. It appears in all herds from time to time and is present most of the time in all herds of more than a few cows. The streptococci found in bovine mastitis may be hemolytic or non-hemolytic but there is no evidence that those found in most cases of mastitis are pathogenic for man.

And again,

> The evidence at hand indicates that milk-borne epidemics of streptococcus infection in human beings are caused not by bovine streptococci but by human strains which may become implanted into the udder of the cow. . . . Milk from cows with mastitis should not be used for human consumption, and no person with a hemolytic streptococcus infection should be allowed to handle the udder of a cow.

More and more each year, the attention of those interested in wholesome milk is focused on mastitis and its control. For years the subject has received the attention of veterinary research workers, of medical and other health officials, of dairy bacteriologists and dairy husbandrymen, and of nearly everyone either closely or remotely concerned with milk in any of its phases. It deserves continued study from all angles, for out of the accumulated information we may expect workable methods of control. Much progress has been made and, in the final analysis, veterinary forces will prob-

ably be called upon, as is already the case in many places, to carry out diagnostic, educational and control measures.

In conclusion, it is evident that veterinary service in the control of milk and dairy products embraces wide and varied fields of activity.

Veterinary service includes the application of control and eradication measures to bovine plagues transmissible to man through milk, as exemplified by bovine tuberculosis. This is an example of joint effort under federal-state guidance in which thousands of official and private veterinarians have participated.

The service includes administrative and inspectional duties under state and local health departments in the enforcement of milk sanitary codes, especially with respect to disease control among dairy herds.

Still another branch includes the veterinary service carried on by private and commercial milk organizations in quality control work among milk producers; this phase has proved one of the most effective and beneficial in the development of improved milk supplies.

Finally, but perhaps most important, are the everyday contacts between practising veterinarians and herd owners in maintaining herds on a healthy and, hence, economic basis.

The primary responsibility for control of milk quality as it affects public health rests largely with medical and other officers of established health department agencies. In discharging the responsibility, a considerable share depends upon the utilization of veterinary personnel and coöperation with veterinary agencies. The extent to which veterinary personnel and veterinary agencies are called upon to perform essential services in milk sanitation depends upon the ability and qualifications of the profession in this field.

The basic and specialized training in veterinary science qualifies the profession in one of the most fundamental aspects of milk hygiene, namely, the health of dairy animals. Superimposed on this basic training in our institutions of veterinary education, are courses in hygiene and sanitation, dairy husbandry, the physical, bacteriological, and biochemical properties of milk, and other instruction which should render veterinary graduates especially well fitted to contribute real service in the development of pure milk supplies. It seems essential that such additional training in hygiene and sanitation should be continued and broadened. In this way, veterinarians and veterinary agencies may be even better qualified and more effective in conserving the interests of animal husbandry and public health through pure milk.

A System of Codification of Medical Diagnoses for Application to Punch Cards, With a Plan of Operation*

JOSEPH BERKSON, M.D.

Division of Biometry and Medical Statistics, The Mayo Clinic, Rochester, Minn.

THE system of coding, which is described here, is an attempt to combine in a single scheme provision for two functions, which are related but not identical: first, the cross-indexing of medical conditions, so that medical histories may be obtained from the storage files, in specified groups, for research purposes; second, the issuing of periodic statistical summaries of medical conditions seen during a definite period of time (yearly reports). While, broadly, these two functions can be thought of as parts of a single comprehensive system of keeping account of medical records, practical considerations make it desirable to plan separately for the needs of the two uses. A few examples will serve to clarify the point.

So far as providing that the record of a given case will be available when it is wanted for study of particular subjects, all that need be done is to enter this record under all the relevant categorical headings representing these subjects. If a given set of diagnostic terms is attached to a history, so far as cross-indexing is concerned, one need not attend to the relative importance or certainty of the various diagnoses, but only to the complete entering of the record under all relevant diagnostic phrases. Thus, to give a simple example, if the diagnostic report in a case reads "carcinoma of bronchus?—or possibly thymic tumor" the case should be cross-indexed under both Carcinoma, bronchus and Tumor, thymus. Anybody who later studies either of these conditions should see this history. On the other hand, for the purpose of statistical enumeration, this would be the worst conceivable disposition, for it would lead to a count of two diagnoses, one, carcinoma of the bronchus, and the other, thymic tumor; whereas, the diagnostician did not mean that the individual was suffering from both conditions, but only that he was uncertain as to which one. For statistical purposes one would have to decide to count the case as one of carcinoma of bronchus, or one of thymic tumor, or one of undefined diagnosis. Another point is that for purposes of drawing individual groups of histories, it is desirable to keep account of certain details, which if included in a general statistical report on all cases, will only tend to clutter it up with small groups and cause confusion. For instance, for purposes of cross-index reference, one may wish to keep distinct, cases of "direct inguinal hernia" from cases of "indirect inguinal hernia," and "recurrent hernia" from "nonrecurrent

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935. The scheme here described is modified for more general application from one in use at The Mayo Clinic.

hernia," but these details may be undesirable for a general report. At the same time, provision must be made that a case of recurrent, direct, hernia shall not be indexed in such a way that it is not distinguished from two cases, one with a diagnosis of direct, and another with a diagnosis of recurrent inguinal hernia and so enumerated as two cases. This point assumes the greatest practical importance if diagnoses have been subdivided into refined subvarieties in the scheme of diagnoses used. For instance, if rheumatic heart disease is subdivided into rheumatic pericarditis, rheumatic mediastinopericarditis, rheumatic myocarditis, rheumatic endocarditis, and so forth, then each of these must be given an independent numerical designation.

If, now, a patient presents a combination of these rheumatic cardiac conditions which in general will be the case, there will be several numbers to assign, and the patient will be counted several times instead of once for what is actually a single condition. Finally, and perhaps most importantly, for purposes of drawing out defined groups of histories to be studied, there is no great significance to the particular order in which the records are kept. It makes no difference whether the records of cases of osteomyelitis are obtained from an alphabetical list under the letter O, or from an anatomic ordering under "bone," since all one wishes, is to get the records of cases of osteomyelitis. However, if all the diagnoses are to be enumerated in a consecutive listing, the ordering and groupings of the list have to be such as to make it intelligible. Furthermore, if the list is to be used for comparative studies, the separate rubrics contained in it should be defined on some standard basis. If one is to prepare for the report of all cases, therefore, one has to deal with a fundamental consideration of the designation of defined rubrics, and in what order they should be arranged, that does not even arise in preparing for cross-indexing. These examples do not by any means exhaust the problems involved in adopting a code to both cross-index and summary enumeration purposes, but they will serve to focus the reasons for some of the particular details included in the coding scheme which follows.

PRINCIPLE OF SCHEME

The principle on which the scheme is built is as follows: The function of summary statistical enumeration (yearly reports) is relegated to a numbering system which occupies 3 columns for what I shall call the "main number." In combination with this, I use a numbering system which occupies 2 additional columns for what I shall call the "subnumber," which performs the rest of the functions of the system. The subnumber is coded in a unique way, for certain definite reasons which will be explained later. Each diagnostic condition therefore is represented by a number combination which occupies 5 columns.

The Main Number—Since the main numbers will determine the rubrics and order of the general statistical report, the disposition of these numbers will depend on what order is decided on. The form of such a listing is necessarily always arbitrary. I have used the groupings and order of the *International List of Causes of Death*, not because that list recommends itself scientifically, but because it is the one which has, at present, the widest statistical application. However, it has been modified and amplified to accommodate it to hospital morbidity conditions.*

* It would be highly desirable to establish a standard form for reporting hospital morbidity similar to the *International List of Causes of Death*. The list used by The Mayo Clinic can be obtained upon request.

The Subnumber—The field for this occupies 2 columns. The coding applied to this subnumber does not follow the usual consecutive numbering that would permit 100 consecutive items in the 2 columns used. Instead, a number is assigned to each of the individual 12 punch positions in the 2 columns, giving a total of only 24 possibilities. I call this the "single-punch method of coding." The purpose of this method is to make possible the punching of multiple simultaneous conditions within each main number, in a single punching field. If the usual consecutive numbering system is used, multiple conditions will require multiple fields. In this method the same punching field can be used for multiple conditions within each main number. The following outline will make this clear:

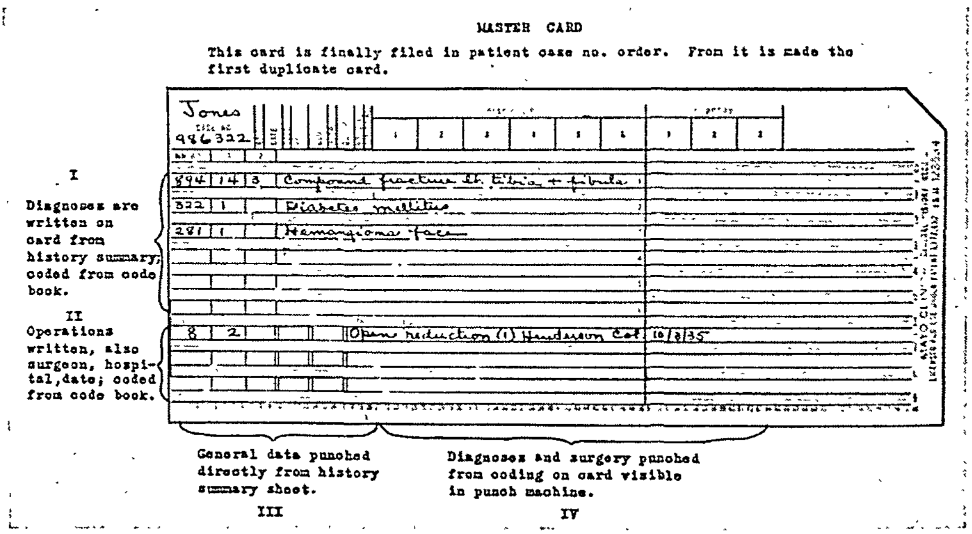
Main number	*Sub-number*	
687	1 —	Inguinal hernia, unmodified
687	— 1	Inguinal hernia, direct
687	— 2	Inguinal hernia, indirect
687	— 3	Inguinal hernia, recurrent
687	—13	Inguinal hernia, direct recurrent

In the last example, direct, recurrent, inguinal hernia is made up by adding the punches of direct and recurrent in the same column, that is, the numbers 1 and 3 are both punched in the second column of the subnumber field. This is possible because only a single punch is used in the subfield for each single specified condition. Advantages of this method are emphasized in the system here described because, as will be explained later, a duplicate card is made for each number punched in a separate field, and by reducing the fields punched it is possible to reduce the number of cards necessary.

OPERATION OF THE SYSTEM

1. *Master Card*—The diagnoses in a given case appear on a summary sheet which the clerk takes up for coding. A special card has been prepared (Figure I) with the punch areas shaded, and between these shaded portions the diagnoses are written in the words given on the summary sheet. A code book alphabetically arranged is provided, and each entry has its code number entered next to it. If the

FIGURE I—A sample master card. The Roman numerals give the order of procedure for completing it.



SECOND DUPLICATE

(The first duplicate is exactly like the Master Card except for the written data.)

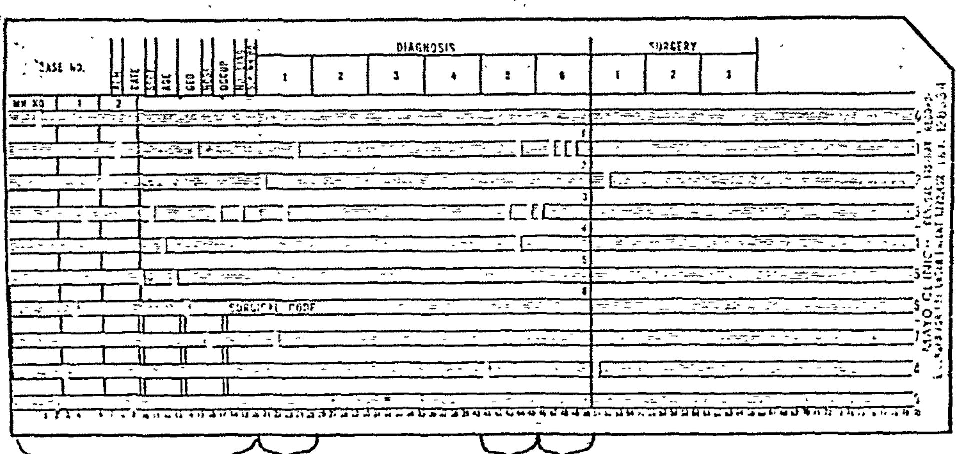
Diagnoses punching shifted.
Diag. No.2 is in position No.1.

THIRD DUPLICATE

This is reproduced from second duplicate.



Straight duplication No.3 No.1 No.2

Diagnoses punching shifted.
Diag. No.3 in position No. 1.

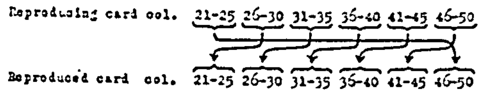
FIGURE II—The second and third duplicates made to complete the cards for the case illustrated in Figure I. Both duplicates are made with the mechanical reproducing punch machine.

condition is one to be included in the statistical summary, an x is punched in the third column of the main number field, in addition to the number shown in the code book. For instance, to take the example previously cited, if the diagnostic sheet says " carcinoma of the bronchus?—or possibly thymic tumor," the numbers for both diagnoses are punched, but only the carcinoma number has the x punched. There is room for 6 such diagnostic fields. When more are necessary, an auxiliary master card is prepared. There is also finally punched, in a column assigned for the purpose, the number of diagnostic fields which have been used; this is to facilitate the preparation of duplicates, which will be described.

2. *Duplicates*—The completion of the punch cards as so far outlined does not render them ready for practical use. It would be impracticable to sort the entire series of accumulated cards each time the records of cases corresponding to a particular diagnosis were wanted. Moreover, since the diagnosis in question might have been punched in any one of the 6 successive fields, all the cards would have to be sorted in that number of fields, a task which would be prohibitive if a large accumulation of cards was involved. Therefore, some system of duplication of cards is necessary.

There are now prepared from each master card, as many duplicates as there have been fields punched, which will be the same in this system of coding, as the number of diagnoses different in respect of the main number. All the master cards prepared as described, are assembled periodically (each week) and from these, duplicates are made on a special colored card. The reproducing machine of the International Machines Co. permits the easy duplication of cards with a transfer of columns. The duplicate is made in such a way that it has the diagnosis for which it is made, in the first diagnostic field, no matter in which field it was punched on the master card (Figure II). To accomplish this, the reproducer is wired so that fields 1, 2, 3, 4, 5, 6 of the reproducing card are punched in the order of 2, 3, 4, 5, 6, 1 on the reproduced card (Figure III).

FIGURE III—The scheme of wiring the reproducing punch machine for punching the duplicates in order to make the pertinent diagnosis appear always in the same columns.



Thus, diagnostic field 2 is shifted to the position of field 1. If 3 or more fields have been punched, the second card is now used as the reproducing card, resulting in the third duplicate having the fields in the order of 3, 4, 5, 6, 1, 2; thus the third field is shifted to the position of field number 1. This is continued progressively for as many fields as occupied.* This procedure is actually extremely easy, because the number of diagnostic fields occupied on the master card has been punched in a special column, and the master cards are first sorted on this column to determine how many duplicates are to be made. I have found that about 1,500 master cards can be duplicated, sorted, and filed in less than 2 hours.

3. *Filing of Cards*—When the duplicating process is completed, we have the master cards and the duplicates to file. The master cards are ordered on the patient case number (not diagnoses), and are placed in a file in this order. Here are kept, in patient number order, consecutively, all the master cards with all the diagnoses written on them. The duplicate cards are ordered

* Where more than 6 diagnoses have appeared on the summary sheet, an auxiliary master card has been made, so that the operation of making duplicates is the same.

on the 3 columns of the main number in the first diagnostic field (all the relevant diagnoses are now in the first field on the duplicates) and are placed in a file of duplicates, each set of cards corresponding to a particular main number behind a tab card bearing this number.*

4. *Utilization of Cards After Filing*—Cross-index. If one is concerned with obtaining, for research reference, the case number of histories corresponding to, say, indirect inguinal hernias, which were recurrent, one determines the number for this, which is 687—13. All the duplicates under tab number 687 are removed from the file, and by using the selecting mechanism of the sorting machine, the cards with punches 1 and 3 in column 5 are selected. The selected cards are now ordered on patient case number, and by using the "controlling" device of the tabulator, a list is obtained of case numbers in order, each case appearing only once no matter how many duplicates (visits) this patient has made. At the same time, a count of patients (control count) and visits (card count) is obtained if desired.

Report. For a periodic summary enumeration, one goes to each set of duplicates consecutively from main number 001 forward, and in each group, first sorts on column 3 of diagnostic field 1 to obtain the x cards (those to be reported). The selected cards are then ordered on patient case number, and are run through the tabulator for a "controlled" count (to obtain a count of each patient only once). The main numbers which represent the rubrics used for summary report purposes and totals are printed on the tabulator print sheet consecutively, so that this sheet need merely be copied to give the final summary report.

* In sorting the duplicates, I have arranged to sort with them a specially prepared tab punch card with the number printed on the tab so that the duplicates after ordering are conveniently separated by these marked tabs and easily filed.

SUMMARY OF PROCEDURES

1. On registration of a patient, a blank master card is filled in with name and patient number and placed in a file, awaiting the dismissal of the patient. This is merely a check to prevent the missing of histories.

2. After dismissal of patient, the history of the case is sent to the indexing department, where the previously prepared master card (see 1) is removed from the waiting file. On this card, a clerk copies in appropriate spaces the diagnoses and operations; and then codes these on the same card from an alphabetically arranged code book (Figure I).

3. History and master card go to a second clerk who independently checks the coding.

4. The master card is taken up by a punch clerk who punches from the summary sheet of the history, general data (columns 1 through 20). The coding of the diagnoses and operation (see 2) on the card in the punch machine is now visible to the punch clerk, and from these the punching is completed (columns 21 through 65). The number of diagnostic fields occupied is also punched (column 19).

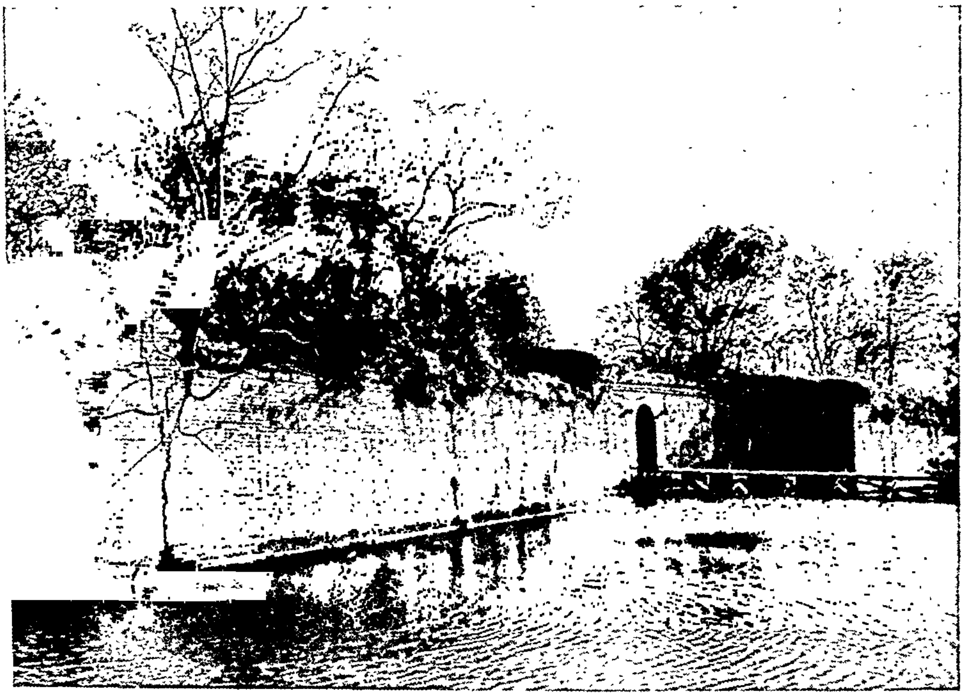
5. The history and master card pass to a checking clerk who independently punches the first duplicate from the notes on history and the coding on the master card. The card is light-checked by this clerk with the original master card. This step is included as a check on punching. These two cards later are checked again for punching, by running them through the checking device of the reproducing machine.

6. The accumulated first duplicates are sorted on the previously punched number of duplicates (column 19) into groups requiring 2, 3, 4, 5, 6 duplicates. Each of these is run through the

duplicating machine the required number of times. For the cards having six diagnoses, for instance, the second duplicate makes the third; the third, the fourth; and so forth, until the sixth is complete.

7. The master cards are sorted on patient case number and then filed.

8. The duplicates are sorted with inserted tab punch cards on the main number of the first diagnostic field (column 20 through 22). This groups them in main number order and they are so filed.



Old Fort Macomb, formerly Fort Woods—Located on the Old Spanish Trail 22 miles east of New Orleans at Chef Menteur. Built in 1842 on land which was formerly the property of the King of France. This great mass of embattled brick with all the typical accoutrements of an ancient stronghold of war, with turrets and moats and drawbridges, is one of a considerable number of old forts to be found in the vicinity of New Orleans.

Industrial Sanitation as a Public Health Engineering Activity*

CHARLES L. POOL, F.A.P.H.A.

Sanitary Engineer and Chemist, State Department of Public Health, Providence, R. I.

THE Committee on Industrial Hygiene of the Conference of State Sanitary Engineers in 1932 canvassed their membership to learn the status of work in industrial hygiene done by the various states. From the data condensed into their report [1] and from subsequent inquiries it is evident that the engineering branch of industrial hygiene, which we are calling industrial sanitation, could almost be appropriately described as a public health engineering inactivity. "Industrial sanitation" is intended to mean primarily the measurement and control of environmental conditions of atmosphere, illumination, and protection against toxic or devitalizing exposures, and not primarily the sanitary engineering specialties of water supply and disposal of wastes as applied to industry.

Connecticut has perhaps the only state department of health in which industrial sanitation is beginning to be at all adequate. *Public Health Bulletin 184* (1932) [2] gave the appropriations for the 4 states having separate bureaus or divisions of industrial hygiene. At that time the Connecticut bureau had an appropriation twice as great as that for any of the other 3 states, and it has since made an addition to the personnel working at industrial sanitation. Its growth to meet a demand justifies the department's article [3] on the necessity for the bureau.

Industrial sanitation is to some extent an activity of a few state departments of health not having special bureaus. Certain large cities are beginning to carry out programs, as may be learned, for example, from the publications of the Baltimore Department of Health. Departments of labor in a few states have divisions devoted to industrial sanitation, and individual industries have made noteworthy progress.

Nevertheless, widespread application of the technical knowledge of industrial sanitation which has been amassed in quite recent years has lagged. No great elaboration is required to convince members of this organization that its application is needed, but should they desire to present the case to others, a few additional references may prove valuable.

Dr. Jirka [4] has summarized the scope of the problem, and statistics showing the need of control measures, including the appalling statement that workers, because of industrial hazards, have 5 years cut from their average life span as compared with those of similar economic status employed in non-hazardous occupations.

Bloomfield and Johnson [5] conclude from a study of a typical industrial area that a constructive program of industrial hygiene should be established in the department of health.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

The 615 plants surveyed showed exposure to 39 different materials and conditions which involved possible systemic poisoning. Inorganic dusts, carbon monoxide, and lead were the most important hazards, all of which are amenable to engineering attack.

These are recent examples from a growing body of literature confirming the need of the work. Why has this need not been met?

That appropriations have been inadequate is not a full answer. It remains not only for pioneers to demonstrate that appropriations are justifiable before the movement can spread on a broad front, but also for a number of departments to take it up successively and show that the program is generally applicable. At present this appears to be progressing slowly.

In some cases appropriations can be obtained when it is shown from experience elsewhere that the need exists and that means are available for meeting the need with real accomplishment. In other cases it is incumbent upon health departments to make a start and demonstrate what can be done with existing appropriations and by existing divisions.

Whether appropriations are to be sought, or a program, however modest, is to be initiated to demonstrate the possibilities, it is the province of the public health engineers attached to the departments to advance the movement. Industrial sanitation is so peculiarly an engineering problem that its widespread advancement has lagged for want of engineering initiative, because the medical direction of the engineering aspects of industrial hygiene cannot be advanced without engineering assistance.

This brings us to the point of this paper, namely, that progress has been retarded because public health engineers have been too preoccupied with sanitary public works projects during an abnormal period of readjustment to have been able to keep up with the advancing knowledge of industrial sanitation in its scattered and largely undigested form. This is especially true in departments where the only public health engineers are sanitary engineers not grounded in industrial sanitation, lighting, ventilation, etc., as recommended by the Committee on Qualifications of the Conference of State and Territorial Health Officers.[6]

It is to these latter engineers that this paper is particularly addressed, for we hope to show how sanitary engineers may extend their work to include industrial sanitation. The nature of their fundamental training and experience fits them for such work; it is only a matter of application of new variations of old principles.

While these variations are numerous in the multiplicity of hazards encountered, the majority fall within a few groups. This makes it possible for a few sets of apparatus and procedures for sampling and determinations to cover a large proportion of the problems in practice, and possible for a relatively small variety of remedies to reduce most hazards.

Taking the typical industrial area mentioned, where inorganic dusts, carbon monoxide, and lead were the most important hazards, the attack would be started by the usual qualitative inspections, followed by such determinations of concentrations of these contaminants in the workroom atmospheres as appeared desirable.

The Greenburg-Smith impinger would serve to sample either the dust or the lead. If this sounds unfamiliar to the sanitary engineer, let us say that the determination for lead consists of the blowing of a measured quantity of lead laden air through water against a surface and analyzing the water.*

* An analysis for lead developed by Howard[7] in New Hampshire, due to simplicity of manipulation, is more fool-proof than the standard methods.

It would not take long to train someone to make determinations for dust or lead, nor to do the sampling and determination for carbon monoxide. The greatest hurdle for the sanitary engineer has been taken when he has obtained a list of apparatus needed and a working outline of standard procedure. We will come to the selection of these definite items from the maze of literature.

Next, where the fairly definite standards established for maximum allowable concentrations of these substances are exceeded, the correction demands that the public health engineer outline to the manufacturer what is practicable. In some cases manufacturing processes can be modified to suppress generation of an excess of the contaminant; for example, dust may be wet down as it forms, or hoods may be installed to collect it before it diffuses into the air. Improvement of general ventilation may be indicated, and much may be accomplished by good "housekeeping." Uncontrollable contamination may demand as a last resort that respirators be worn.

The control or modification of the process, the collection and exhaust of the contaminant, the improvement of ventilation or "housekeeping," and the determination whether the respirator is effective involve the same principles that sanitary engineers apply to the treatment of water and wastes.

Industrial hygienists might at this point notice an incompleteness. But we are confining our exemplification to industrial sanitation, stopping where it begins to overlap the phases which belong under immediate medical direction.

Full fledged experts in industrial sanitation should be attached to departments of health, but until they are procurable, we believe that public health engineers in most departments should, and could, initiate and carry out programs, notwithstanding the fact that such extension involves the work of years rather than of months, and that an approach without a full course of special training demands that branches of the work be mastered and applied one by one.

During the present plastic stage of the art, certain aids would be of immense assistance to public health engineers. Visits by experts of the U. S. Public Health Service for the express purpose of instruction in programs and technic would be invaluable. Intensive courses in industrial sanitation planned like the 2 weeks' courses given to health department personnel at the U. S. Public Health Service Stream Pollution Station in Cincinnati are needed. If such courses were confined to procedures which have proved practicable, omitting alternative methods, methods infrequently encountered, and general instruction in non-engineering phases of industrial hygiene or its administration which could be read up at leisure, engineers receiving the instruction could be equipped to undertake a considerable variety of original investigations.

We would also suggest that a committee of this Association might be appointed to compile a manual of industrial health engineering practice as was done for water works by the American Water Works Association, and this is something that need not necessarily be delayed for want of means of financing.

If selected contributors could be recruited among technicians of bureaus of industrial hygiene, industrial hygienists of insurance companies, industrial chemists, research workers, and faculties of schools of public health, etc., it should be possible to assemble an eminently practical manual from knowledge already available, despite the fact that much of the so-called "engineering" practice has yet to be put on a scientific basis, as is instruc-

tively shown by Hatch[8] in the case of dust control. The manual could be confined to practical working information on industrial sanitation, could omit other aspects of industrial hygiene, and could exclude, but refer to, material already in accessible form in a few publications which those using the manual would be expected to own. By so confining its bulk, the task should not prove too formidable. One publication in particular, the 2,300 page *Encyclopaedia of Hygiene, Pathology and Social Welfare,* should be in the possession of industrial sanitarians, and on the assumption that those going into the subject seriously would obtain it, the bulk of our manual could be kept down by avoiding repetition of its contents. Turner[9] declares this encyclopedia of industrial hygiene to be the most complete and reliable reference work of its type. But it does not preclude the necessity of a practical working manual.

Among the few other publications that such a manual might refer to rather than repeat may be mentioned the bulletin *Determination and Control of Industrial Dust,* by Bloomfield and Dallavalle.[10] There is no reason for such a manual to duplicate the contents of a standard textbook, and we understand that the first one on dust is under preparation by Drinker and Hatch, of the Harvard School of Public Health.

Such a manual could fulfil the lack of assembled information in giving working directions for analytical determinations of concentrations of various substances in air, with diagrams of apparatus, methods of calibration, tabulations of threshold concentrations, substitutes for hazardous substances and for what processes their use is practicable, known modifications that could be applied to unsatisfactory processes, design data on actual installations for exhaust and ventilation systems and their performances, data on actual practice in progressive industries where hazards are guarded against, etc. A fund of unpublished information could doubtless be ferreted out by a coöperative effort among a well selected group of contributors.

We agree with the opinion of Cook[11] that no one has prepared a treatise on industrial health engineering because it would grow obsolete faster than an individual could prepare it. Therefore, a condensed manual prepared by a committee appears to be the logical solution.

Public health engineers have the choice of attending to the development of industrial sanitation or seeing this work established by engineers in departments of labor. For instance, the Division of Occupational Hygiene of the Massachusetts Department of Labor and Industries was recently created, as described before the section on occupational diseases at the Massachusetts Safety Conference[12] in 1935.

This trend represents a good development through the wrong channels. Engineers developing industrial sanitation in departments of labor have not the medical, technical, and laboratory facilities to support them that are available in departments of health. Industrial sanitation aims to elevate health and is a natural part of the public health organization of the country. Its objectives should come under constant medical scrutiny without which it can have no intelligent objectives. The work should be evaluated under medical supervision in order that its cost may be apportioned properly in relation to other public health activities. To disjoin an important branch of technical work from a public health organization detracts from the strength and value of that organization and offers no compensating advantage. The position of state departments of health between federal, on the one hand, and county, municipal, and local departments of

health on the other, together with their accustomed coöperation in all aspects of health control, makes the department of health the logical organization to supervise this work in the interests of efficiency.

While industrial sanitation is a tool of preventive medicine and should be so organized, we believe there is a strong reason why engineers should head divisions prosecuting this work under departments of health in coöperation with medical experts in industrial hygiene rather than as subordinates to them. The reason is simply that its importance and difficulty demand able engineers, and you will not, in the long run, find many engineers of outstanding ability in subordinate positions in departments of health, if competition for leadership is denied them.

This paper could have come to a logical end on this note had we not already sent the Association an abstract stating that two other items were discussed: (1) The expansion of sanitary engineering activities in an industrial state to include industrial sanitation as a forerunner to the creation of a separate bureau; and (2) Legislation which was introduced to establish an adequate industrial inspection service jointly by the Rhode Island Departments of Labor and of Public Health.

Our activities are proceeding along lines advocated herein. While it has been impossible as yet to carry out an adequate program, we have done a considerable variety of work in industrial sanitation in the past 3 years, and have come to be called upon so frequently that if legislation is not obtained soon to establish the work on a recognized footing it will have been established by precedent.

This was made possible by the addition in 1931 of a second assistant sanitary engineer to our personnel and by other sympathetic and material assistance by those in a position to dispense such things.* Our ability to attack such problems as arise has been dependent in no small degree upon the advice available from the Harvard School of Public Health, the Connecticut Bureau of Occupational Diseases, the U. S. Public Health Service, and the National Safety Council.

Finally, as to our legislation—Acting under authorization of the Director of Public Health, legislation was prepared in coöperation with our legally trained Director of Labor and introduced before the close of our last session.

It was aimed to create a bureau in the Department of Public Health with a nucleus of trained personnel and enlarged laboratory facilities, which would devote full time to industrial sanitation. Conjointly it was aimed to create a bureau in the Department of Labor with a nucleus of trained personnel who would coöperate with the Department of Public Health, have access to their laboratory facilities, and who would exert a technical educational influence on the non-engineering portion of the inspectional staff of the Department of Labor. It was specified that the data or reports of the bureau in the Department of Public Health could not be used in court, since it was desired to keep this bureau on a solely advisory basis, which, as attested by Gray,[12] is of great importance if the full coöperation of manufacturers is to be had. At the same time, it would be understood by manufacturers that bad conditions might be referred to the Department of Labor for the obtaining of evidence to be used in the enforcement of laws. This attempt to provide both the benefits of a bureau confined to advisory service and an enforcement agency which would be able to obtain

* The Rockefeller Foundation provided a fellowship covering attendance at the courses in industrial hygiene given by the Harvard School of Public Health.

the technical evidence needed departs from the precedents offered by the two states adjacent to Rhode Island.

We expect to continue the expansion of activities in industrial sanitation and are hopeful of successful action on the legislation this winter. Passage of such legislation has been recommended by our Governor.

Cultural Methods of Isolation of Tubercle Bacilli*

A. L. MacNABB, B.V.Sc., F.A.P.H.A.
Director of Laboratories, Ontario Department of Health, Toronto, Ont.

IN a previous report[1] we outlined the results obtained in a comparative study of cultural and animal inoculation tests carried out on 343 specimens of sputum. As the cultural examination was found to be more sensitive, and as it is free from disadvantage of test animals dying from intercurrent infection, we decided to extend our cultural study to all specimens received upon which an animal test was requested. The routine followed was a cultural examination on sputum specimens and a cultural and animal inoculation test on all specimens of pleural fluid, ascitic fluid, joint fluid, and glandular material.

METHOD OF PROCEDURE

Pure cultures of *M. tuberculosis* can be isolated or obtained directly from tuberculous material, if the tubercle bacilli are present in sufficient numbers and mixed infections are not present, by using the proper blood serum or egg culture medium. If organisms other than tubercle bacilli are present, and as these organisms grow more rapidly than tubercle bacilli, the specimen must be treated preparatory to culture.

METHOD OF TREATMENT

Several methods of treating specimens have been tried in the Ontario Department of Health Laboratories. We have found the low grade acid treatment for 2 hours, with subsequent neutralization by the addition of 3 per cent sodium hydroxide solution, to be the most satisfactory method tried to date. The procedure briefly is as follows:

1. The specimen when received is placed in a sterile 6 inch test tube, care being taken to deliver it to the bottom of the tube. Every precaution should be used to prevent as far as possible contaminating the side of the tube. The neck of the tube is well flamed and a sterile cotton plug is inserted.
2. Equal parts of 3 per cent hydrochloric acid containing bromcresol indicator is added to the specimen. Should there only be a sedimented specimen, 5 c.c. of this reagent is added. This acid solution is 3 per cent of the concentrated hydrochloric acid, and is not 3 per cent hydrogen chloride.
3. After the addition of the 3 per cent hydrochloric acid solution to the specimen, the tube is shaken by a side to side motion, and the upper portion of the tube is well flamed to within an inch of the upper level of the liquid. A fresh sterile cotton plug is inserted in the tube.
4. The specimen is left at room temperature for 2 hours, after which time it is neutralized by the addition of 3 per cent sodium hydroxide (pH 7.0). This reagent is added aseptically in the tube.
5. A rubber cap is placed over the tube in order that the cotton plug will be held in place. The neutralized specimens are then centrifuged at high speed for ½ hour.
6. After centrifugation, the supernatant fluid to within ½ inch of the sediment is withdrawn by means of a suction apparatus, which is attached to a rubber tubing on a flask containing phenol 5 per cent.
7. By means of a platinum loop, a beef infusion broth culture is planted with a loop-

ful of material from each specimen. These broth cultures are incubated at 37° C. for 24 hours, and then examined for turbidity in the liquid. These broth cultures indicate whether or not all extraneous organisms have been destroyed in the treatment process.

8. All the specimens showing no growth on the broth are then planted by a sterile capillary pipette on various types of media suitable for the primary growth of tubercle bacilli.

CULTURAL PROCEDURE

In our first series, a platinum loop was used in seeding. At least 3 or 4 loopfuls were placed on each slant. In the second series, a capillary pipette was used. At least 3 drops of the treated sediment are placed in each tube. After seeding, the upper portion of the culture tube is flamed, the cotton plug ignited, and inserted in the tube. A rubber cap, boiled for 15 minutes, is placed over the end of the tube. The specimens are incubated at 37° C. for 8 weeks. The cultures are examined after 4 weeks. Cultures showing visible growth are examined, smears prepared, examined, and reported. Others are incubated for a further 4 weeks.

Petragnani's positive on 170 or 76.9%
Lowenstein's positive on 187 or 84.6%

Lowenstein's Silica positive on 163 or 73.7%
Woolley's positive on 171 or 77.4%

CULTURE MEDIA USED

A number of media have been proposed. In connection with our work, the following media have been used:

1. Lowenstein's
2. Lowenstein's with silica
3. Modified Petroff's
4. Petragnani's
5. Woolley's medium with and without glycerine
6. Feldman's modification Herrold's medium
7. Dorset's
8. Modified Dorset's
9. Lowenstein's and Petragnani's medium to which silica has been added

STUDIES MADE

From October 1, 1932, to June 30, 1933, each specimen was planted on 2 modified Petroff's, 2 Woolley's, and 2 Petragnani's culture tubes. From July 1, 1932, to January 1, 1934, these were supplemented by 2 Lowenstein's, 1 Petragnani's containing 1 per cent sodium silicate, and 2 Woolley's slants without glycerine. Of the media used, Lowenstein's and Petragnani's yielded the greatest number of positives.

Table I shows the number and percentage of positive cultures obtained from each of the 3 types of medium used. Petragnani's media gave the most positives, and Woolley's least. Woolley's media showed a rather high percentage of contaminated tubes. When malachite green is added to this medium, instead of crystal violet, it yields very satisfactory results.

Table II shows the number of specimens examined in Series No. I.

Of 1,826 specimens examined, 201, or 11 per cent, were positive, of which 146 were found positive in 4 weeks, while 55 required 8 weeks' incubation.

Specimens on which culture was controlled by guinea pig inoculation, in Series No. I—Table III shows the results obtained in examining 642 specimens by both the culture and animal inoculation. The cultural test yielded

TABLE VII

	629	523	106	527	102

105 positives, and the animal inoculation 88.

Specimens on which culture was positive and guinea pig inoculation negative, or *vice versa*—Of the 642 specimens included in this comparative study, 28 yielded positive cultural results, while the animal inoculation yielded 9. Animal inoculation yielded positive results in the case of 1 ureter, 1 joint fluid, and 1 sputum, in which cultures were negative.

During 1934, the media used was Lowenstein's, Lowenstein's with silica, Petragnani's and Woolley's with and without glycerine. Feldman's media was tried, and Woolley's media with phosphate buffer. We discontinued the use of modified Petroff's, as it had no advantage over Woolley's and was less efficient than either Lowenstein's or Petragnani's. In addition, a further cultural test was made on 302 specimens, using Lowenstein's, and Dorset's containing sodium silicate.

A second cultural study was made on 226 specimens in which 4 different silicates were added to Petragnani's medium. The result of this work is as follows: During the year 1934, the animal inoculation test was carried out, using a portion of the untreated specimen, while in 1933, the test animals were inoculated with a portion of the treated specimen.

Table V shows the number and

TABLE VIII

ANALYSIS OF COMPARATIVE TESTS

Sputum	0	0
Pus	2	3
Joints and Bone	4	3
Miscellaneous	0	2
	13	17

nature of specimens examined during 1934. Of 2,329 specimens cultured 9.49 per cent were positive, of which 74.2 per cent were found positive in 4 weeks, and 25.8 per cent after 8 weeks.

Table VI shows the results obtained in using Petragnani's, Lowenstein's, Lowenstein's silica, and Woolley's medium.

Table VII outlines the results from 629 specimens cultured and inoculated.

Table VIII shows that in Series No. 2 cultures were positive in 13 instances in which animal inoculations were negative, while animal inoculations were positive in 17 instances in which the cultures were negative.

SUMMARY

Cultural examination for the primary isolation of tubercle bacilli was carried out in 2 series, which include all the routine specimens received at the Central Laboratory, Ontario Department of Health, during 1933 and 1934.

For 1,826 specimens, Petragnani's, modified Petroff's, and Woolley's media were used routinely. Dorset's and modified Dorset's media were tried, but found inferior, and their use was discontinued. Of the 3 media used, Petragnani's yielded the greatest number of positive results (Table I). On 642 specimens, the cultural examination was controlled by animal inoculation. Cultures were obtained from 105 specimens, while 88 produced typical tuberculosis in animals, inoculated with 1.5 c.c. of the treated sediment.

For 2,329 specimens, Lowenstein's medium with and without sodium silicate, Petragnani's and Woolley's medium with and without glycerine, were used throughout the series. Feldman's medium was tried, but was not as satisfactory as the others, and was discontinued. Of the media, Lowenstein's gave the most positives (Table VI), of which 74.2 per cent were visible in 4 weeks.

In a further comparative study of cultures and animal inoculations on 629 specimens, the animals gave positive results for 4 more specimens than the cultures. The animals were inoculated with 1.5 c.c. of the untreated specimen.

CONCLUSIONS

1. Cultural examination for the primary isolation of tubercle bacilli has been found to be equally as sensitive as the animal inoculation test.
2. The cultural examination is free from the disadvantage of test animals dying from intercurrent infections. In 77.2 per cent of the positives a report was available in 4 weeks.
3. Our results indicate that on specimens other than sputa and chest fluids, both a cultural and animal inoculation test should be carried out.
4. The results obtained indicate that further studies on suitable cultural media and animal inoculation tests should be carried out.

Integration of the School Health Program with Community Health Education*

V. S. BLANCHARD

Director, Health and Physical Education, Detroit Public Schools, Detroit, Mich.

ONE of the most significant changes that have become evident because of the economic upheaval in recent years is the interest which the community has taken in the public school system. This interest has not always been completely altruistic, but it has caused the schools to take inventory, criticise their curricula, and analyze their programs in the light of their contributions to the community.

Has the school health program of the past been integrated with community health education? Before attempting to answer that question and before venturing any suggestions as to present or future integration there should be a clear understanding as to what constitutes a school health program and how we are to define community health education.

Any successful school health program must concern itself with three distinct factors: (1) healthful school living, (2) health service, and (3) health instruction. Furthermore the content of the program must be adapted to the age level of the child, that is, whether he be in the elementary, junior high, or senior high school. There are some differences of opinion among school people as to just what should constitute the specific programs on these three different levels. The ones cited here seem to be meaningful and in accord with present-day educational concepts.

Health work in the elementary schools should consist of a program built around the child's everyday school experiences. It should aim toward the inculcation of health attitudes and health habits with as much actual health teaching as is consistent with the elementary school child's ability to absorb it.

The junior high school program may combine some of the work on the elementary level with one period a week devoted to definite health instruction as outlined by a course of study supplemented with textbooks.

Presupposing that such a program as briefly outlined is operative in the elementary and junior high school, the senior high school student should be given an opportunity to appraise his own health needs and be given guidance and help in meeting them.

What aspects of such a school program as this may be carried over into the community, and how may the community supplement such a program with its health education program? Again to answer this there must be a clear understanding of what constitutes com-

* Read at a Joint Session of the American Association of School Physicians and the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

munity health. Community health consists of the coöperation of the citizens in the community; a safe milk supply; an adequate pure water supply; careful food inspection; sanitary disposal of city waste, garbage, and sewage; protection against communicable diseases; mental hygiene; and lastly but increasingly imperative, education in health.

Too little emphasis has been placed on education in health, both in our schools and in the community. Too much emphasis has been placed on health service in our schools with the result that boys and girls have been graduated from high schools totally ignorant of how to meet their health problems as they arise. The home, the most vital place in the welfare of the community, has waited for the child to go to school to get a health check-up. The school has examined the child, made some spasmodic and sporadic attempts at following up defects, and then has set him loose on the community to duplicate later the mistakes of his mother and father.

It is one of the jobs of the school to see that boys and girls are thoroughly familiar with community health problems before they are graduated from high school. Furthermore, they must be instructed as to how they are to meet their own health needs. This entails familiarizing them with hospitalization, *i.e.*, what hospitals are available, their location, and their particular functions; with clinics and their particular function in the community; and with the medical profession and its societies. This last is of particular importance. Some communities are taking definite steps along this line through written communications, from the local medical society, the board of education, and the board of health jointly, to parents urging them to take their children to their private physician for a physical examination before the opening of school. Remarkable results have been attained in some schools through such a program. As high as an 80 per cent response has been achieved. Such an attempt as this serves the triple purpose of educating the parent as to the health needs of the child, of familiarizing the child with ways of securing health service, and of acquainting the physician with some of the health problems confronted in schools. As this plan becomes perfected, more time may be devoted by the school physician in individual check-ups and less to wholesale physical examinations.

The physician may also be brought more closely into sympathy with the school program of health and physical education by asking him to specify what of certain health and physical education activities a child may indulge in, rather than issuing a blanket excuse from all phases of the program. A modern curriculum of health and physical education includes opportunity for participation in (1) rest, (2) walking classes, (3) light work in the gymnasium, (4) corrective work, (5) regular gymnasium work, (6) athletics, (7) swimming, and (8) health instruction. Surely if a child is able to come to school at all he can take part in some phase of this program. It is the duty of the school to acquaint the physician in the community with the fact that the physical training and physical culture classes that tortured him have been replaced with a comprehensive program of games, athletics, stunts, swimming, and dancing, as indicated. The time has passed when the private physician merely sends a note to the school in his community which says, "Excuse Mary Jones from gym." It is only through the close coöperation of the agencies just mentioned, namely, the local medical society, the board of health, and the board of education, that such integration between the home,

school, and physician may be achieved.

Boards of health are recognizing more and more the crying need for further health education of the community. It has been a slow process through the era of sanitation of the environment and the era of bacteriology to the individual, just as it has been a slow process for boards of education to recognize that there are individual differences among children and that these must be considered not only from the academic standpoint but also from the standpoint of his social, emotional, and physical health.

Some of the media employed by boards of health in their community health education program include the radio, the press, health contests, exhibits, special campaigns, billboards, parent teacher associations, the schools, local service clubs, etc.

There is a definite integration of the school health program with several of these. The radio is an outstanding example. In Detroit there are weekly broadcasts on pertinent health matters. Many of our schools are equipped with radios. Health instruction classes meeting at the hour when these programs are being broadcast tune in on them. The messages are thus going both into the home and into the school.

One of the projects instituted in health instruction classes in the schools consists of analyzing and evaluating health material found in magazines and newspapers. Material in the latter in particular deals largely with local community health problems. Free discussion of these problems develops a worth while community consciousness.

Nutrition classes and home nursing classes have been organized in many schools under the supervision of the board of health. These classes meet a very definite community need particularly in certain socio-economic centers where there are many large indigent families. The older sister brings many healthful changes into the home that would otherwise not have been made. Nutrition classes have of course been particularly valuable during the depression.

Little need be said about parent-teacher associations. This is a fertile field for integration of school and community health and it has been well used although much more might be done.

There are many other agencies, governmental, voluntary, or business, which are leading the way in health education of the community and are also supplying valuable material for the school health program. It is only necessary to mention a few of them to call to mind their significant contributions: The U. S. Public Health Service, state and city departments of health, Visiting Nurse Associations, juvenile courts, National Red Cross, American Social Hygiene, National Health Council, American Physical Education Association; various foundations such as the Commonwealth Fund, the Kellogg Foundation; and various business organizations including the National Dairy and Food Council, life insurance companies, etc.

Special consideration should be given to the work of the National Safety Council and its local branches since accidents have become of such vital concern to every community. This is an outstanding example of the extent to which integration between school and community may go when each is aroused to the seriousness of a situation. Here we find police departments, the American Legion, chambers of commerce, and local service clubs working in close harmony with school authorities in decreasing the incidence of accidents. All of these agencies are endeavoring to educate the public in accident prevention. The results of their coöperation with the schools in an educational pro-

gram to prevent accidents, particularly vehicular ones, are seen in the steady decrease of child injuries and fatalities. Were we to attain an integration of the school health program and community health education equal to that attained between safety education in the schools and the community safety program we would see a tremendous change in the health of our entire citizenry. It is not beyond attainment and, to recapitulate, the experiences of the last 5 years have brought about changes that have stirred all of us out of our lethargy.

Terminal Disinfections

FIVE full years have now elapsed since routine steam disinfection was discontinued, and the following table shows in summary form the results of the last 5 years compared with those of the 5 years immediately preceding. In the table the results of 5 years (1925–1929), during which steam disinfection had been carried out, can be compared with those of 5 years (1930–1934) during which it had been abandoned. The table shows at a glance the total number and also the percentage of secondary cases occurring in premises from which the original cases had been removed previously. By way of explanation, it should be pointed out that, in the final comparison, secondary cases occurring within a week of the primary case have been excluded, the reason being that such cases occurring within the known incubation stage of the two diseases may have been infected by the primary case before removal to hospital.

Period	*Steam Disinfection*	*Disease*	*Cases Notified*	*Cases Removed*	*Secondary Cases After 7th Day*	*Percentage of Secondary Cases*
		S.F.	2,054	1,315	80	6.03
1925/6/7/8/9	Practised	Diph.	1,538	1,272	59	4.63
		Total	3,592	2,587	139	5.37
		S.F.	2,542	1,683	104	5.51
1930/1/2/3/4	Abandoned	Diph.	1,050	896	33	3.68
		Total	3,592	2,579	137	5.31

It will be seen that, in the case of scarlet fever, the percentage of secondary cases has dropped from 6.08 per cent to 5.51 per cent, whereas the relative figure for diphtheria has fallen from 4.63 per cent to 3.68 per cent during the two periods under review. When comparison is made between the total figures (including both scarlet fever and diphtheria) it will be seen that the percentage of secondary cases has diminished from 5.37 (with steam disinfection) to 5.31 (without steam disinfection).—*Andrew W. Forrest, Leyton—Pub. Health,* Mar., 1935, p. 239.

Preliminary Report of the Sub-Committee on Educational Qualifications of Public Health Engineers*†

SCOPE OF PUBLIC HEALTH ENGINEERING

THE field for engineers in public health work has been restricted largely to state health departments with a few openings in city, county, or district health departments. In general, the technical education of public health engineers thus employed has been in sanitary engineering, or in civil or chemical engineering, with courses in general sanitation. These courses have been confined primarily to the subjects of water and sewage treatment and industrial waste disposal with the necessary chemical and biological instruction.

Formerly, and in some states still, engineers with state health departments dealt principally with problems of water, sewage, and industrial wastes. While still an important work of state health departments, these are now only one branch of engineering activity; as for the engineer of the city or county health department, these may be of minor consideration.

At present a few schools offer courses in the subject but, generally speaking, engineers have found it necessary to obtain a considerable part of their public health education through experience. This condition will probably continue until public health administrators exact an adequate degree of graduate education comparable with the responsibility of positions to be filled.

At present the outlook appears favorable for the development of the well rounded health organization, both state and local, with properly qualified personnel. In such departments there is a rather broad field for the engineer qualified to do public health work.

A study of the activities of a well rounded health department shows that environmental sanitation in its broadest sense constitutes a considerable part of the work of the department. In administering this important but nonmedical work, basic engineering knowledge and some knowledge of a variety of other professional and technical branches would appear essential. To administer properly the various public health engineering activities, and to assist and advise the health officer in matters where both medical and nonmedical knowledge is necessary, requires graduate education.

Briefly, some of the activities now being carried on by engineers connected with health agencies, or activities that by their nature would appear most logically to fall under the administration of one having proper public health engineering education, are as follows:

1. The group of activities having to do with water, water supply and treatment, sewerage and sewage disposal, industrial

---

* Committee on Professional Education, American Public Health Association.

† The Committee on Professional Education requested publication of this report to permit the members and Fellows of the American Public Health Association to review it for the purpose of offering criticisms and suggestions to the committee in the further consideration of the reports.

wastes disposal and stream pollution correction will naturally come first. These activities require a knowledge of engineering and such collateral subjects as chemistry, bacteriology, and water biology.

2. The sanitation of rural and recreational areas, including camps, swimming pools and bathing places, schools and public places.

3. The collection and disposal of municipal wastes, while not generally classed as an activity of a health department, always require the attention of health authorities, and it is believed that the problems involved in this activity can best be solved by an engineer having a public health viewpoint.

4. Sanitary control of foods, including the production, pasteurization, and distribution of milk, and the sanitation of the shellfish industry in the coastal states. These varied problems are largely of an engineering nature but also require some knowledge of food technology, chemistry, and biology.

5. Suppression of certain insects capable of transmitting disease occupies a considerable portion of the time of some engineers now with health departments. Rodent control should also be included with insect control activity since both endemic typhus and plague are transmitted through the rat flea. Engineering knowledge and some knowledge of entomology and biology are required in this class of health work.

6. In cities particularly there are many and sundry problems which engage the attention of the engineer of the health department. These include questions of proper city planning, of housing, of heating, lighting and ventilation of buildings, of plumbing, of aerial pollution, and of noise. These problems are largely engineering in character and could best be handled by an engineer with a public health viewpoint.

7. In the epidemiological studies of many diseases, in statistical studies and in the educational program, the engineer should take a considerable part.

8. Obviously the direct supervision of personnel engaged in environmental sanitation should be under the engineer.

Due to the variety of work of an engineer in a health department, it is not reasonable to expect that during an undergraduate course sufficient training can be given to enable him to solve these varied problems. In the future it seems essential that undergraduate instruction be followed, either as it has been in the past, by a period of years devoted to sub-professional and professional work under the supervision of a more experienced engineer, or that provision be made for an additional educational program extending beyond that required for the bachelor degree. It is recognized that most practising public health engineers have acquired this preparation by practical experience. It is also recognized that no educational policy can be formulated that will provide the thorough education that can come through such experience. The public health engineer who has had the opportunity to secure this education by years of experience has a distinct professional advantage over the engineer entering the public health field for the first time. It must be recognized therefore that in the existing field of public health engineering practice there are many engineers who have not had postgraduate education but who are fully qualified through experience to carry on public health engineering activities.

EDUCATIONAL QUALIFICATIONS

The basis of public health engineering education should be engineering.

The duties of the committee are to determine what the minimum of education should be beyond that possessed by a graduate of engineering in order that he may enter a health agency as a public health engineer. Even with this education it is obvious that such a young man would necessarily be in a subordinate position, except possibly in a small unit, until such time as he had acquired the necessary experience to permit him to occupy an administrative position.

In many ways the additional education required beyond that included in the usual engineering course is quite similar to that which would be required for a medical man desiring to enter the field of public health as an administrator. The engineer who adopts

public health as a career should have, in general, educational qualifications somewhat comparable to those of a medical man entering this field. In other words, the public health engineer should be first a graduate engineer, and then should have in addition from 1 to 2 years in graduate work which should include the subjects listed below, since not all of these subjects or their equivalent can be covered in the undergraduate work.

While courses in civil or sanitary engineering or optional courses probably offer the best foundation for public health engineering work, the committee would not confine the basic education in engineering necessarily to these courses. Engineering courses with electives in subjects on sanitation appear satisfactory for basic education, provided courses in sanitary bacteriology, sanitary chemistry, and personal hygiene are included.

It is recommended by the sub-committee that, in addition to the subjects normally required for a bachelor's degree in a curriculum outlined above, graduate work should include instruction in:

1. Biostatistics sufficient to give the individual a sound conception of the mass phenomena of disease, familiarity with methods of collecting, recording, and studying statistics on vital phenomena, and ability to interpret the results of the analysis of such material
2. General or theoretical epidemiology, including instruction in the collection, recording, analysis, and interpretation of epidemiological information regarding those diseases toward the prevention and control of which the public health engineer would be expected to contribute
3. General historical background of health administration and a general knowledge of the organization and functions of the national, state, and local health administrative units
4. Fundamentals of common law
5. Sanitary biology and instruction in interpretation of laboratory reports and methods of administration and operation of laboratories in connection with public health work
6. Food technology, with particular reference to production and pasteurization of milk, and familiarity with methods of protection against such diseases as may be transmitted by foods
7. Entomology as it applies to those insects which may be vectors in disease transmission and in methods of this control
8. Housing with respect to health
9. Lighting, ventilation, and plumbing sufficient to give the individual some knowledge of these subjects
10. Industrial sanitation, particularly with reference to certain hazards the correction of which is largely an engineering problem
11. Environmental sanitation as it applies to rural areas and to recreational facilities

Certain subjects above indicated may also be required for health officers. It is believed that instruction in these subjects should be essentially the same for both groups.

Where sufficient instruction in any of the subjects listed has been obtained during the undergraduate course, such subjects need not be repeated.

It is not advisable to attempt to set up any definite schedule of hours of courses, since experience is necessary to determine the proper allotment of time to such courses. This should be left to the educational institutions.

It is considered essential that the experience offered, in lieu of such formal instruction, and also the instruction leading to a position of administrative responsibility, shall be acquired under the technical supervision of experienced public health engineers.

It is the sense of the committee that the title of an engineer who has completed this formal instruction or who has acquired the equivalent through experience should be "Public Health Engineer."

Preliminary Report of the Sub-Committee on Educational Qualifications of Sanitarians*†

THE duties of this group of health department employees have a wide range, since the carrying out of the environmental sanitation program in all its complexities is its function. These duties can be performed best by one having a technical background, since the problems are largely of a technical nature.

The sanitarian and the public health nurse are the two classes of employees of the health department who come more closely in contact with the general public than any other class of employees. As a consequence, the public judges the efficiency of the health department largely by the work carried on by these two groups.

It seems essential, therefore, that the sanitarian should have sufficient education, including field experience, to permit him to meet the public and to discuss intelligently the work in which he is engaged.

EDUCATIONAL REQUIREMENTS FOR SANITARIANS

Title I

Sanitarian—The committee recommends that the title for one class of employees be "Sanitarian," with such prefix as the training in a particular branch of public health work would indicate. However, when the term "Sanitarian" is used without prefix it should designate a person who has had certain basic instruction in engineering and who later by additional work, may qualify as a public health engineer.

The committee recommends:

1. That the educational requirements be a bachelor's degree from a recognized institution of learning, followed by at least a 1 year course, or its equivalent, in certain subjects necessary for one entering the public health field. Undergraduate work should include science courses, particularly biology and chemistry.
2. The subjects required should be such as to give a general knowledge of health department activities and include some intensive instruction along one or more lines of health work. The intensive instruction might well be grouped under the 3 headings: general sanitation, sanitary control of foods, and control of the environment.

General instruction is recommended in:

1. Biostatistics
2. A general knowledge of epidemiology, including methods of collecting, recording and interpreting epidemiological information regarding those diseases toward the prevention and control of which the sanitarian would be expected to contribute
3. Health administration sufficient to give a general knowledge of the forms and methods of operation of health departments

Special instruction is recommended in:

---

* Committee on Professional Education, American Public Health Association.

† The Committee on Professional Education requested publication of this report to permit the members and Fellows of the American Public Health Association to review it for the purpose of offering criticisms and suggestions to the committee in the further consideration of the reports.

1. General sanitation, including nuisances, water supply, sewage disposal, rural and recreational sanitation, mosquito control, and rodent control; or

2. Sanitary control of milk and foods, including laboratory procedures and methods of protection against such diseases as may be transmitted by foods; or

3. Control of the environment, to include housing, plumbing, lighting, ventilation and industrial sanitation.

It is assumed that the undergraduate course would serve as a guide to the individual in the special line of instruction selected for graduate work. Where sufficient instruction in any of the subjects listed has been obtained during the undergraduate course, such subjects need not be repeated.

Title II

Sanitary Officers—It is realized that the employment of personnel not having the educational qualifications above specified will continue until public health administrators are able to require higher standards in this phase of public health work.

During the interim it is recommended:

1. That non-professional employees be given the title of Sanitary Officer;

2. That the educational requirements be not less than graduation from high school and at least 1 year's experience in some line of work that has brought the individual in contact with the general public; and

3. That steps be taken by the health agency to supplement the employee's education in health work by courses equivalent to a 2 year college course; or

4. The completion of a 2 year course in an institution providing a course of instruction in public health prior to employment;

5. That individuals not having had instruction or experience in health work should not have exceeded 35 years of age at time of first employment.

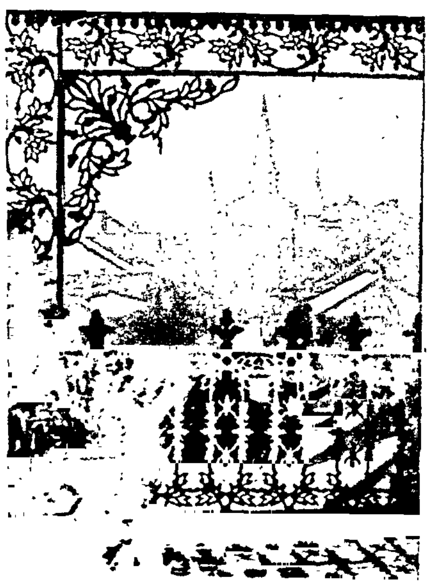
THROUGH A FRAME OF GRILL
NEW ORLEANS

The Vieux Carre, or Old Quarter, of New Orleans is rich in architectural antiquities. Through the cast iron and hand-embroidered iron work of antebellum slaves can be seen from this Pontalba balcony many colorful vistas of Old New Orleans. The St. Louis Cathedral, built in 1792–1793, is shown in the background.



EDITORIAL SECTION

THE SURGEON GENERAL OF THE PUBLIC HEALTH SERVICE

THIS *Journal*, representing one of the oldest health organizations in the world, and the oldest in America, offers congratulations to Thomas Parran, M.D., on his appointment as Surgeon General of the U. S. Public Health Service. It also offers to the Service itself and to the country, congratulations on the wise selection of the President for this most important position. We pledge to Dr. Parran our support and aid in carrying out the duties and responsibilities of his new position.

The appointment fulfils an expectation of several years' standing, during which Dr. Parran has held the important position of Health Commissioner of the State of New York, a position affording abundant opportunity to observe him in action and become familiar with his methods.

Dr. Parran enters on his duties about a year after the passage of the Social Security Act and directly after the appropriation was made which put that Act into effect. For the first time in our history the government has appropriated large sums of money for a national health program designed to be continuous, and which, without taking from the individual states their responsibilities and authority, will lodge in Washington a supervisory service carrying with it financial aid as well as professional counsel. The administration of this Act, although outlined in the creative law, will tax to its utmost the Public Health Service. The law requires that the Surgeon General confer with the State and Territorial Health Officers, and he has accepted the report of a committee of that body and incorporated its conclusions into the administrative regulations. Inasmuch as 16 of his 20 years of service have been in state health departments, Dr. Parran will doubtless endeavor to carry out the sound programs of the state health departments.

The personnel of the U. S. Public Health Service constitutes a large and exceptionally well trained body of public health experts, in every recognized phase of the work. The history of the Service and its achievements gives us assurance that within his organization the Surgeon General has at his command the best of advice as well as the best in the practical field.

It is well to recall something of the history of our Public Health Service, created in 1798 with the principal object of protecting maritime trade. It was known for years as the Marine Hospital Service. In 1902 it became The Public Health and Marine Hospital Service, and only in 1912 did it acquire the name which it now carries, the U. S. Public Health Service. In 1901 the Hygienic Laboratory for the investigation of infectious and contagious diseases was authorized, and in 1912 authorization for research was extended to include all diseases of man and conditions influencing the propagation and spread thereof. In 1930 further facilities for research were provided, and the name of the Hygienic Laboratory was changed to National Institute of Health.

The Service has always answered every call made upon it promptly and efficiently. Following the World War, the Service was designated as the principal agency to care for World War veterans in need of hospital care. Tremendous responsibilities were placed upon it at practically a moment's notice, and to its credit let it be said that though it was in contact with some of the most notorious scandals of the early post-war period, it escaped contamination, and investigations showed that it had been conscious of its responsibility, had provided hospitalization for veterans in the emergency, and had protected the government and the public under most trying circumstances.

Our government has never recognized the necessity of a national board of health, headed by an officer in the Cabinet of equal rank with those in charge of labor, agriculture, commerce, and similar major governmental activities. The World War taught both England and Canada the importance of the creation of such departments. In 1879, under the threat of an epidemic of yellow fever, a national board of health was created, but through lack of appropriation, almost as soon as the fear of yellow fever was over, this organization sank into innocuous desuetude, and some years later (1893), the law creating it was repealed. Many of the functions of a national board of health were assigned to the Public Health Service. Step by step these responsibilities have been increased and the field of endeavor has been enlarged; but in spite of what the Service has accomplished and the general recognition of the important place it holds, it is still a bureau of the Treasury, with an Assistant Secretary of the Treasury in direct charge.

In the April, 1936, issue of this *Journal* there was published an article by Dr. Parran, entitled "Health Security." In that article he mentioned several important problems confronting health workers that require attention at the present time. These problems included the completion of our job against tuberculosis, a real campaign against syphilis, the making available to people everywhere of facilities for the proper diagnosis and treatment of cancer, the reduction of death rates of mothers in childbirth, and babies in their first month of life, the correction of conditions resulting from improper diet, and the restoration of crippled children to lives of usefulness. It is evident that Dr. Parran has hitched his wagon to a star—a commendable aim.

It may be properly inferred that Dr. Parran considers these as major objectives of the federal and state governments in connection with the inauguration

of more extensive health work throughout the country under the Social Security Act.

It would appear that Dr. Parran is a happy choice in the selection of a Surgeon General confronted with the work of carrying out the provisions of the Social Security Act with relation to its public health aspects. In this task we wish him success and assure him of support and active assistance so far as lies within our power.

WORK FOR THE EDITOR

"BRING candid Eyes unto the perusal of men's works, and let not Zoilism or Detraction blast well-intended labours. He that endureth no faults in men's writings must only read his own, wherein for the most part all appeareth white. Quotation mistakes, inadvertency, expedition, and human Lapses, may make not only Moles but Warts in learned Authors, who notwithstanding, being judged by the capital matter, admit not of disparagement. . . . Capital Truths are to be narrowly eyed, collateral Lapses and circumstantial deliveries not to be too strictly sifted. And if the substantial subject be well forged out, we need not examine the sparks which irregularly fly from it."

This is the statement of an unusually wise man. Can we accept it? It contains much that is true, but lapses of several authors, such as those quoted by him, have led to much that is incorrect in history and emphasizes the advice of Oliver Wendell Holmes, "not to take authority when I can have facts."

Just at this time, papers are being prepared for the Annual Meeting of our Association and prospective authors are preparing material with which they hope to enlighten the world. There are times when a conscientious editor becomes very pessimistic, especially just after an Annual Meeting, when it becomes necessary to read and judge several hundred papers. One might take the kindly view expressed by Sir Thomas Browne, and even adapt the words of Cowper, "A heavenly mind may be indifferent to her house of clay, and slight the hovel as beneath her care," but we cannot bring ourselves to believe that this would make for good literature or clear understanding.

We do not wish to be pedantic, but certain expressions better avoided often occur. It is true that English is a growing language. Many words have gained new meanings, others which were correct are now incorrect or impolite; and some formerly incorrect now appear in good company. What are we to think of the professor of public health at one of our leading universities who twice in one paper assures us that a large number of children have had "diphtheria inoculations"? The editor often feels that the most unkind thing he could do to some authors would be to publish their papers exactly as they are written.

Writers seem to have a spite against certain words; "suspicious," for example, as "suspicious pneumonia." "Total" is more often used incorrectly than correctly, when the writer refers simply to a certain number—cases or population, for example. The word "period" is much abused. Instead of saying "from Tuesday to Thursday," for example, or "during 48 hours so and so occurred," we find "during a period of time extending from Tuesday to Thursday," or "a period of time of 48 hours duration"—a waste of words, if no worse. Period has several meanings. Fowler says: "A period is an era regarded as destined to run its course and be succeeded by a similar succession." The word "enhance"

seems to be growing in popularity. It sounds learned. Fowler says it is "a dangerous word for the unwary." The word "case" is a nightmare as used. The patient is not the case, the patient dies or recovers; the case terminates fatally or in recovery. The surgeon operates *in* a case but *on* the patient. Such statements as "the case gave the following history" are entirely incorrect. Another word often wrongly used is "such," for example, "when there are epidemics or impending danger of such." We often find such expressions as "The reason lies in the fact that," when it would be more clear and simple to say, "The reason is." We frequently find such statements as "Examinations, all of which were normal," meaning that the materials examined were found to be normal. One of the most common mistakes is to use "affect" for "effect" and *vice versa.* We also find such a statement as, "this disease is very fatal," as though there were degrees of fatality itself. It would be easy to extend the list of words wrongly used; but these will suffice for our present purpose.

At an Annual Meeting, at the request of a chairman of a certain session, some suggestions on the writing of papers were given. All that was said there holds good. We ask writers not to pad their papers for any reason. Historical introductions are sometimes useful and interesting, but generally the shorter the better, and seldom is there any reason for more than a few lines. Padding with quotations should be avoided. A recent contribution had some 7 pages of quotations. It is fair to assume that anyone enough interested to read a scientific paper, either has the material from which these quotations were taken, or can obtain it. Practically all journals have cut down on bibliographies. Unfortunately, in many cases there are grave doubts as to whether or not the many authors referred to have been consulted. The writer has found the same error in almost the same words running through more than 12 successive articles, evidently one quoted from the other, illustrating further the advice of Holmes. The reference was the same, and the error did not exist in the original.

One is tempted to close with an incident. A few years ago a paper was submitted which was almost unintelligible. The author of the paper had been entirely wrong in his judgment of an outbreak and of its source. He had been corrected as to facts but his ideas were still hazy and his English, if possible, was worse. The paper was practically rewritten by the editor. The statistics were corrected and made intelligible by one who understood figures, and a presentable paper was the result, yet an English journal picked this paper out for special comment.

NOTE: There are many good books on the writing of papers. The standard is *Notes on the Composition of Scientific Papers,* by Sir Clifford Albutt. American books are *The Writing of Medical Papers,* by Maud H. Mellish Wilson, and *The Art and Practice of Medical Writing,* by Simmons and Fishbein, now badly in need of revision. Several universities have their own style manuals, one of the best being that of the University of Chicago Press.

FLOODS AND THE MILK SUPPLIES

WHEN floods, tornadoes, and other disasters strike, the newspapers usually devote many fervid columns to sensational and dramatic incidents, but seldom mention the routine services that are equally significant to the protection of life and health. In describing deaths, injuries, and individual acts of heroism,

the press often overlooks the somewhat prosaic activities of the doctors, nurses, and sanitarians who are mobilized to give relief and prevent disease, and they rarely notice such humble servitors as the dairymen and food purveyors whose diligent activities often avert malnutrition and even starvation.

During the recent devastating floods in the United States, local dairymen performed especially noteworthy services. With bridges down, roads impassable, railroads out of commission, and most of their territories under deep water, the dairy companies sent fleets of trucks hundreds of miles to get the milk through. They overcame almost insurmountable difficulties in order to maintain deliveries of pure, pasteurized milk, and in some instances had to employ airplanes to transport necessary pasteurizing machinery for emergency use.

Milkmen, who were often on 24 hour duty, commandeered rowboats, powerboats, canoes, and rafts for their deliveries; they waded waist high through swirling and dangerous currents; they climbed precariously along fences and over narrow planks, so that no child should be deprived of this essential food. Farmers appeared around the bend of what had once been the road, in boats or on horseback, carrying cans of milk that distributors could pasteurize and bottle for prompt delivery under hazardous conditions to private homes, to the marooned and to refugees, to national guardsmen and Red Cross workers, and above all, to the mothers of infants and young children.

The dairymen and the milk companies in the flooded regions made contributions to public health that the local health officers will not soon forget. Their achievements and sacrifices were recognized editorially by a number of leading newspapers, including the *New York Times*, indicating that the public as well as the medical profession is not unappreciative of the labors of its milkmen heroes during this calamity.

PUBLIC HEALTH EDUCATION*

"When the literary apprentice has read the masters of the English tongue he should know 'classic' English when he sees it. This is every man's best foundation style, whether he wishes to write novels, become a journalist, or write letters home to mother.

"There is no great gulf between 'classic' English and newspaper English at its best. The aim of both is effectiveness of assertion. And effectiveness of assertion, says Bernard Shaw, is the Alpha and Omega of style."

In "Learning to Write" in "Writing for the Press," by L. Russell. A. and C. Black, London. (Macmillan Company.)

Ninety-Nine Thousand Deaths—"Accidents of All Types Take 99,000 Lives During 1935" is the title of a press release from National Safety Council, 20 N. Wacker Drive, Chicago, Ill. *Free.*

Among the details is the 1 per cent increase of deaths by motor vehicles, and the occupational accident deaths, less than half those due to vehicles, and less than half what they were 25 years ago!

Five Little Teachers—Again the 5 little Canadian girls have served their sisters throughout the two countries. In the last week of March, N.E.A. Service syndicated "Dr. Dafoe's Own Story of the Quins." The delightfully conversational statements about the mental and physical health of the babies seem to offer much quotable material, but N.E.A. Service has informed us that the writings of Dr. Dafoe may not be reproduced, or quoted.

A New Service and a New Periodical — Adequate provision for public health education is promised through the newly organized Office of Public Health Education, U. S. Public Health Service, Washington, D. C.

An official announcement of the rather heavy undertaking of the new office is quoted from *The Health Officer:*

> The responsibilities of the U. S. Public Health Service are increasing along with the increasing complexity of modern life. Although the dissemination of knowledge is now generally recognized as a supreme duty, not only of educators, but of public health workers, and, indeed of all scientists, no organized and concerted effort has been made by the Service, up to the present time, in the field of health education.
>
> Such an effort has been initiated in the recent establishment of the Office of Public Health Education, under Assistant Surgeon General L. R. Thompson, Chief of the Division of Scientific Research. The purpose of this office is to carry out certain experimental studies in health education.
>
> The initial activities of the Office of Public Health Education embrace 6 major duties. First, the training and instruction of young commissioned officers of the Service; second, special instruction for educators, health officers, and sanitarians from state health departments, and from health departments of

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

foreign countries, and for other eligible individuals. Third, the office will make studies of educational methods employed in various health agencies and in other fields of education, with a view to adapting the methods to our own purposes, and to developing new and improved methods. Fourth, experimental studies in mass adult education, through the use of the radio, will be made for the purpose of evaluating various methods of radio education. Fifth, permanent records of available material will be filed and will be a repository of authoritative information in the field of health education. Sixth, the Office of Public Health Education will prepare a bulletin of current health information, primarily for the personnel of the Service. The first issue of this bulletin is now in the hands of its readers and is titled *The Health Officer: A Digest of Current Health Information.*

Advances in the general sciences and in medical science, especially, leave us wondering how it is possible for the health officer to acquire, hold, and augment his knowledge of the ever expanding fields of public health and preventive medicine. One of the primary functions, then, of this office, will be to issue a monthly digest of current public health information, for commissioned and other officers of the Service, for health officials throughout the country, and for those of the laity who are interested.

The purpose of *The Health Officer* is to report the activities and progress of our fellow officers in the various stations of the Service. Current happenings in any branch of personal, community, or public health, and in other branches of science concerned with the public welfare, will be reported.

Each month, *The Health Officer* will present abstracts of important and pertinent articles from the current literature in community health and sanitation, public health administration, public health methods, preventive medicine, personal hygiene, social sciences related to medicine, and other related fields. Reviews of significant books in these fields will be included.

The Health Officer, as its title and aim indicate, is "of" and "for" the health officer of today. That it may also be "by" him is the hope of the Office of Public Health Education. Any officer possessing information of general interest to the personnel of the Service is invited to write the office about it, in order that the news may be shared through this publication. Officers are further invited to outline their own activities by summarizing the material and submitting it for future issues of *The Health Officer.*

The 23 letter-sheet mimeographed pages of the initial issue include:

an announcement of the new service, a welcome to Dr. Parran, "Commissioned officers' training course now in progress," book reviews, abstracts of articles, and "annotated articles."

Write U. S. Public Health Service if you wish to receive copies.

Now Easier to Handle—Have you noticed the added words and numerals at the tops of pages of the *Journal,* starting with January, 1936, issue?

A helpful device for those who receive an extra copy of the *Journal* so that articles may be clipped and filed by topics or by prospective uses. At least many of the clippings will be dated automatically at the top.

A set of *Journals* plus classified clippings makes the ideal set-up for wider use of the magazine.

An Exhibit May Be Too Lifelike—Models of buildings or displays using human figures, animals, etc., may be too lifelike to be educationally effective. The more nearly perfect such displays are the more likely that visitors will be so absorbed in the perfection of the figures or buildings that they get little of the lesson supposed to be taught. And dolls are equally distracting. Either they are foolishly "doll-like," or they are such "cute" lifelike reproductions.

More effective, and less expensive, are photographs mounted and cut out. Such cut-out photographs used by Pennsylvania Sanatorium for Tuberculosis and by Henry Street Visiting Nurse Service are shown in "Publicity for Social Work," by Routzahn (Russell Sage Foundation). See opposite page 300.

Negro Health Week Any Week—The annual Negro Health Week is past, but Dr. R. C. Brown, Director of

the Week, U. S. Public Health Service, Washington, D. C., calls attention to the fact that in numerous communities for various local reasons, Negro Health Week will be celebrated at a later date.

For copies of the program, a sermon, and a radio talk, write to Dr. Brown.

A program folder is neatly done on one sheet with French fold, printed both sides. The sheet, 19½ x 12½ inches, is folded twice so that the 4 chief pages are seen as 9¾ x 6¼ inch pages. When the whole is unfolded there is the 19½ x 12½ inches for an inspirational display of activities and printed matter gathered from many cities in previous years.

Health Education in Canada—As reported in *Canadian Public Health Journal*, 105 Bond St., Toronto, Ontario. April, 1935. *35 cents.*

Public Health Education Section of Canadian Public Health Assn.: Chairman, Dr. G. F. Amyot, North Vancouver; Vice-Chairman, May Power, Toronto; Secretary, Dr. Stewart Murray, Vancouver.

In the joint health meetings at Vancouver in June, 1936, the newly formed British Columbia Health Assn. will unite in one session with the Public Health Education Section under the chairmanship of Dr. Amyot.

In the May, 1936, annual meeting of Ontario Health Officers' Assn., Dr. D. V. Currey, Medical Officer of Health, St. Catherines, Ontario, presented "The Local Board of Health as Its Own Publicity Agent."

A page is given to a tuberculosis exhibit in Vancouver, B. C.

"Brantford, the 'No Diphtheria Town'" tells of Brantford's annual immunization campaign in which a letter to parents said:

> Dr. Dafoe gave the toxoid treatment to the Dionne quintuplets; your baby is deserving of the same protection.

A brief report is given of the Eighth Annual Conference on Health Education, organized by the Central Council for Health Education, held in London on November 21, 1935.

The Martin Family Broadcasts—Several years ago this department of the *Journal* expressed its appreciation of the Martin family broadcasts put on in Racine, Wis. Dr. W. W. Bauer, then Racine Health Commissioner, and Mrs. Bauer were responsible for this effective pioneering in the use of simple dialogue in broadcasting.

In *Hygeia,* May, 1936, Dr. and Mrs. Bauer, under the heading, "The Martin Family Vacation," explain the idea, and present two of the episodes.

> The dramatized radio health episodes in this series are selected from 115 such programs broadcast by the Health Department of Racine, Wis., in the last 9 months of 1931, by courtesy of the radio station of the *Racine Journal-News,* now the *Journal-Times.* They have been rebroadcast by medical society and medical auxiliary groups locally. They have been edited and brought up to date for this, their first publication. . . .
>
> The simpler programs here published were broadcast originally with casts furnished by dramatic classes from the William Horlick High School and the Woman's Club of Racine. They can be used as brief platform episodes with simple stage settings, as radio broadcasts over a school public address system or as class-room projects for pretended broadcasting. Teachers will readily find ways of using them and of interesting the classes in providing sound effects, settings, and other accessories.
>
> Any medical society, health department, or voluntary health organization organized and administered not for profit is granted permission to produce this material, provided no admission charge is made. Credit should be given to *Hygeia* and to the authors. If the radio episodes are to be used in a program broadcast at regular intervals (weekly, for example), a uniform introductory announcement like the following, modified to suit local conditions, may be used. It is spoken by the station announcer or by the sponsor of the program, not by one of the players in the episode to follow. It is more effective when spoken "above" the music; that is, with the music toned down to a faint background

for the words, then swelling again to full volume when the speaker concludes:

"During the next 15 minutes we bring you the program of the .... This program, which comes to you each .... at ...., is broadcast under the auspices of the .... which believes that the health of the people is the greatest asset of the community and that health is based primarily on knowledge and understanding of the principles that govern it. Watch for this broadcast regularly at the same hour each ...."

When the episodes are used as platform sketches a dark stage with a radio instrument on which a spot of light is trained, leaving all else invisible, is effective. Under such conditions the same announcements may be used as for radio presentation, but of course the sketches must be memorized, while for the radio they are read from script.

The episodes may also be presented as sketches on a set stage; the setting in each case is suggested by the announcement preceding each script but should not be elaborate in any event. In such a case the announcements would be modified or omitted, especially if a printed or mimeographed program were distributed.

The episodes are best presented in series. They may be used to fill a large gap or just a "spot" in the radio or platform program, as the case may be.

Plan of the Individual Broadcasts—Sequence: Chimes or fanfare. Introductory musical theme begins forte, fading after about 1 minute. Introductory announcement "above" pianissimo musical background: Station Announcer. Musical theme finishes forte. Day's announcement: Station Announcer. Dialogue (10 to 12 minutes). Closing announcement: Station Announcer. Closing music, same as opening theme. Chimes or fanfare.

A phonograph record is suitable for the musical theme. Under present radio commission rulings, a phonograph record used only as an introductory theme incidental to other material need not be announced as a record. The selection should be a lively one, such as "The Parade of the Wooden Soldiers," or a march, like "El Capitan," or "Officer of the Day," but it should not be jazz.

The May issue of *Hygeia* reproduces "What Kind of Vacation?" and "The Doctor Suggests."

If you are at all interested in popular health broadcasts we hope that you will read these two episodes. Further installments will appear in *Hygeia.*

Home-Made Silhouette Making—For exhibits and for printed matter, silhouettes offer effective illustrations. The *New York World-Telegram* (March 21, 1936) tells how to make them—

With a bed sheet, a bridge lamp and a floodlight bulb the amateur photographer can amuse himself by making silhouettes while he waits to take his camera outdoors.

In this simple sideline to indoor photography, anyone can give free play to ability in composing a picture, with the problem of lighting reduced to the A B C's. A little imagination and experiment in posing will be rewarded with silhouettes that are dainty and graceful, amusing or startling in their portrayal of personality.

To make camera silhouettes, hang up a large sheet smoothly so it comes to the floor. A wide doorway is a good spot. Five feet behind the sheet place a bridge lamp with a 750-watt photoflood bulb and a silvered reflector. See that the lamp illuminates the sheet evenly.

Pose the person or group to be silhouetted 2 feet in front of the sheet.

Use fast film for indoor photography. Set the camera, on a tripod or table, far enough from the subject so that it is all visible in the finder. Arrange it for a time exposure, with the diaphragm at stop 8 on cameras using the "F" system, or at stop 1 on cameras with stops numbered one to four.

When the picture has been posed have the subjects remain motionless and turn on the flood lamp and expose for two seconds.

A good way to time a two-second exposure is to open the shutter, say aloud, "A thousand and one, a thousand and two," and close the shutter.

Try To See It as He Will See It—If you issue a small sized mimeographed report, and if you wish to use some tricky folding, ask for a copy of the 1935 report of the Meriden, Conn., Public Health and Visiting Nurse Association. And if you make use of the "Do You Know" form of stating certain facts about your agency note the possible gain in making the heading read "Do You Know That";

and if you have a folded step back front, and if you have a last line making an important point, note how you could make this line and the preceding one into a complete statement, provided that the last line is centered and set in the same type style as the one visible above it. In other words, scrutinize your dummy for additional touches, whatever form of report you may issue. Try hard to see it as it will look to the man who receives a copy of the completed report.

Mailing Lists Are Exasperating—The only answer is personal supervision. And that means a personal examination, say once a year.

Recently experiences of several people have emphasized mailing list possibilities under usual office routine.

When a mailing list is important, or sections of it have much value to your organization it can't be left wholly to routine handling. Whatever the system for handling addresses, it seems worth while for a responsible executive to give it a personal check-up every year or two. Not many health agency lists are so extensive, and their importance so limited, that this could not be done.

"Eye Openers"—Under this title Dr. E. Krimsky answers questions which

> Every doctor will recognize as questions which have been presented to him by patients in the course of his medical experience.

Here are some of the questions:

> Is there danger of eye glasses breaking and causing injury to the eyes?
>
> Will I always have to wear glasses?
>
> Are tobacco and alcohol injurious to the sight?
>
> Are circles under the eyes a sign of eye trouble?

In *Sight-Saving Review*, National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y. March, 1936. *50 cents.*

In the same issue: "Eye Health Primer for Nurses"; "A Sight Conservation Program in School" (Dallas, Tex.); "Eyes Right" (reprinted from *Good Housekeeping*. Feb., 1936).

An Adaptable Idea—*Hoosier Health Herald,* Indiana Tuberculosis Assn., Indianapolis, says:

> The National Tuberculosis Association has compiled a scrapbook in which are mounted all the reprints in the field of school health education distributed in recent years. A person visiting that office may see this splendid portfolio which contains reprinted articles on "Healthful School Living," "Health Service," and "Health Instruction." Until articles of this nature are brought together and mounted, one hardly realizes what a wealth of material is available.
>
> Local tuberculosis associations may profit by this suggestion and arrange in a scrapbook or portfolio material which they make available to school teachers. Thus teachers may look over the material which is available and more wisely select those things which meet their needs. A scrapbook is especially good, for it may easily be taken out of the office to teachers' institutes or teachers' meetings where it will prove very useful. A loose leaf folder makes it easy to remove out-of-print material and to add new things from time to time.

An even simpler and less expensive form of portfolio has been used for several years by the Social Work Publicity Council. Kraft (brown wrapping) paper, cut to 14 x 11 inches, 3 holes punched at the left is used. A cover sheet, 14 x 22 inches, is folded once, carries a pasted label, black letters on a gay bit of paper. The number of sheets varies with the subject. It is easy to divide the subject matter for convenient use. Short pieces of cord, about the color of the paper, are tied through the 3 sets of holes in sheets and covers, the knots being placed *inside the back cover.* Many readers have seen these portfolios at Annual Meetings of the A.P.H.A. or the National Conference of Social Work.

The N.O.P.H.N. has a series of portfolios using a more attractive paper cut to 18 x 12 inches.

Make up collections of your own printed and duplicated material. Gather groups of samples from other sources. Whatever subject interests people who come to you for information and advice may be represented by a portfolio, even if the material is limited.

You will be surprised at the interest shown by your visitors, who won't need nearly so much of your time when you can hand them a portfolio to look over.

Lower-Case Heads Win—Probably certain lavish uses of capital letters have misled many who wanted to get attention. We want people to look at what we print. We want people to think what we print is important. So we use plenty of capital letters—and make them as big as we can.

But in the 6th annual Exhibition of Newspaper Typography, sponsored by N. W. Ayer and Son, 8 of the 9 newspapers given awards used lower case headlines, with but limited use of capitals. The 9 were selected from 1,444 newspaper entries. The *New York Herald-Tribune* won over the *New York Times,* the latter being the only one of the 9 making use of all cap heads.

The moral? If newspapers don't need a mass of caps to get attention and to help make sales?

And in Annual Reports Also—"Find it if you can" seems to be the theory which guides health education discussion in health department annual reports.

In this section of the *Journal,* April, 1936, page 424, we called attention to the simple device employed to bring out the health education material in all divisions of the Pittsburgh Health Appraisal report. The absence of that sub-heading, "Community Health Instruction" under any main heading, emphasized the lack of health education activities. This use of the sub-heading also made easily available whatever was said on the subject.

Important health education, likely to be carried on in communicable disease, child welfare, or other bureaus, may not be reported because the chiefs are more interested in other aspects of their activities. An understanding that a public health or adult health education heading should be used if possible, would keep the matter before the chiefs of divisions or bureaus.

The use of data or explanation of a division or bureau might be recorded under this heading. Vital statistics might report the use of data in health education by some other division of the department. Laboratory might report that its services to the public had been reported by the department in broadcasts, a series of news releases, or a newly issued folder. And so with others.

Cancer Education Via Radio—Says *Bulletin,* American Society for the Control of Cancer, 1250 6th Ave., New York, N. Y. (April, 1936):

In the process of developing various methods of reaching the lay public in the campaign of cancer education the radio has begun to assume a position of outstanding importance.

Among the pioneers in the field has been Dr. W. A. O'Brien of the University of Minnesota. For a number of years he has given a weekly health talk over the radio. In this series of talks he has frequently utilized some phase of the cancer problem. This has been accomplished in one of two ways. Either some topic in the field of cancer research, treatment or education has been dealt with directly or information on cancer has been cleverly introduced as a contrast to some other subject under discussion.

The Massachusetts State Department of

Health has also sponsored a series of talks dealing directly with various phases of the cancer problem. The interest in both of these ventures has been sustained and encouraging.

More recently the Cancer Committee of the Louisiana State Medical Society under the chairmanship of Dr. Lanford has conducted a large number of broadcasts. Other states are rapidly following suit. The American Society for the Control of Cancer has built up a series of radio talks on cancer contributed by its directors and by the chairmen of its state and other local branches. These talks are in ever increasing demand from all parts of the country. . . .

Perhaps of even greater significance is the highly successful dramatization of playlets dealing with cancer education. There have been two outstanding pioneers in this respect: the American Medical Association and the New York State Department of Public Health. The former conducts a public health program weekly and has dramatized successfully some aspects of the cancer problem. This program has been broadcast by the National Broadcasting Company from which organization permission to use the material must be obtained.

The New York State Department of Public Health has given a series of playlets known as the Health Hunter Series . . . The acting and voices are excellent. A sound record has been made so that the program can be given throughout the state. The records are in great demand . . .

Each such step in public education buries deeper the rapidly disappearing specter of cancer phobia and serves as a guarantee that the efforts to encourage a more enlightened public attitude toward cancer control are bearing fruit. Knowledge of the success which has attended these pioneer advances should spur others to the utilization of the motion picture, the press, magazines, and the stage as vehicles for expression. The period of free speech on cancer control has only just begun. We may expect the future to provide progress not only in the amount of publicity but in the ingenuity in the forms used to carry the educational message.

Farewell to American Child Health Association—The Sept.-Nov., 1935, issue of *Child Health Bulletin* appeared in April, 1936. Published for a number of years by American Child Health Association, this final issue was devoted largely to "The Story of the American Child Health Association," by Dr. Philip Van Ingen.

It is a heartening record. It will be a revelation to many to read in brief compass the record of the several groups and the combined organization, from June, 1908, through to August 13, 1935. Probably copies of this issue have been received by numerous health and education bodies, and by public libraries.

This issue includes 7 pages of annotated "Child Health Literature," which has been so ably presented for years by Ellen C. Babbitt. Will not some health or education periodical continue this splendid service?

Health Education, Journal, March, 1936—Of interest in *American Journal of Public Health:*

"Laws, Dealer's Insurance" (page 228), editorial from *Daily Record,* is good for use with local milk producers and distributors.

In "Books and Reports" see "Free Medical Care, Socialized Medicine" (page 302), and "Mother and Baby Care in Pictures" (page 305).

On page 310 are listed new members of Public Health Education Section.

Wanted back numbers of the *Journal* are noted on page 286.

An important suggestion appears on page xix. The paragraphs preceding the "form of bequest" illustrates one way of presenting the idea of "gifts and bequests." Too often the "form" is given without any explanation. Any health agency may present its claims in a dignified and effective manner when offering a "form of bequest."

References to health education and to the Public Health Education Section are to be found in the supplement, *American Public Health Association Year Book.*

Be sure to read "The Foreword" (page vii).

The Health Conservation Contest

winners are listed year by year (pages 31–33).

The Committee on American Museum of Hygiene "reports progress" (pages 36–37).

"Food Fallacies and Nutritional Quackery" (pages 58–63), report of the Committee on Nutritional Problems, is likely to be particularly helpful as background material and for direct quotation.

"Methods in Health Education" pages 207–208), is a progress report of a Section committee, Ira V. Hiscock, *Chairman. All concerned are urged to give this report careful consideration, and to submit comment, suggestions, and further questions to any member of the committee.*

In "Public Health Aspects of Noise Abatement" (page 225), report of the Committee on Noise, is a plea for education of the public—

in the needlessness of most noise, its ill effects, and the possibility of its abatement.

Health Education in April, 1936, Journal—Items of interest in the *American Journal of Public Health*, April, 1936:

In "District Health Administration in Large Cities," by Rice and Barnard, see organization charts (page 324), and paragraph on health education (page 326).

"Authoritative Standards and Association Policy," by Frost (pages 336–343), discusses problems which concern the Public Health Education Section and its future.

The group of articles on spray residue on fruits and vegetables (pages 369–389), including references to publicity, may be useful as consumers' groups are aroused by statements of danger from poison on fruits or vegetables.

"Dr. Arthur J. Cramp" (page 381) records the retirement of the long-time chief of what was once the Propaganda and Reform Bureau of the A.M.A., whose record should be known to all who seek to inform the public of commercial dangers to health.

In "Practical Application of An Industrial Health Appraisal Form," by Bristol (page 391), are scoring values suggested for "General Health Publicity" and several health education items under other general headings. See also paragraph on page 394.

"Books and Reports" (pages 432–438) is the annual "review of selected books of interest to public health workers."

Under "A Selected Public Health Bibliography With Annotations" see "Foods That Fight" (page 445), and "Education and Appendicitis" (page 446).

"The Health Conservation Contests" (page 447) is a brief review.

Eight new members of Public Health Education Section are announced (page 449).

Hygeia, May, 1936—Published at 535 N. Dearborn St., Chicago, Ill., the May, 1936, issue of *Hygeia* includes:

Child health . . . Florence Nightingale ("where is her modern counterpart?") . . . Food for two (mother and unborn child) . . . Myths about cancer . . . Helping the child to conquer fear . . . The Jack and Jill house (how the house may be made fit for children) . . . Frauds that flourish until Uncle Sam takes a hand . . . What parents should know about tuberculosis . . . Can you prove that you are a citizen? . . . The case of the pig and the party (a medical mystery) . . . The streptococci (germs we live with) . . . How disease came with the white man (malaria and yellow fever) . . . William Osler (a leader among clinicians) . . . The Martin family vacation (a radio series) . . . The skin in health and disease . . . Babies in bed . . . "Safety First" for children illustrated . . . Health news pictures . . . Questions and answers . . . New books on health.

Under "School and Health" conducted by J. Mace Andress:

Do you know what you may reasonably

expect of your pupils? . . . An experimental program in rural school health education, presented in "Getting results through united effort," "Teacher assistants in health education," and "Building a health education curriculum." . . . New health books for teachers and pupils.

The P.H.E. Section in the Year Book—In the A.P.H.A. Year Book, issued March, 1936, the Public Health Education Section is represented as follows:

Elective Councilors: Philip S. Platt, Donald B. Armstrong, William P. Shepard, John Sundwall.
Associate Editor of the *Journal*: Evart G. Routzahn.
Committee on Meetings and Publications: Homer N. Calver.
Sub-Committee on Scientific Exhibits: Calver, Routzahn, Bertrand Brown, H. E. Kleinschmidt.
Committee on Fellowship and Membership: Shepard.
Committee on Research and Standards: Clair E. Turner.
Committee on Professional Education: Sundwall, and Shepard (Consultant).
Sub-Committee on the Educational Qualifications of Health Educators: Sundwall.
Nominating Committee: Mary P. Connolly.
Sedgwick Memorial Medal Committee: Armstrong.
Committee on American Museum of Hygiene: Victor G. Heiser, Brown, Sally Lucus Jean, Routzahn.
Affiliated State Public Health Societies:
Connecticut: Ira V. Hiscock, Secretary-Treasurer.
Michigan: Marjorie Delavan, Secretary-Treasurer.
Pennsylvania: J. Clarence Funk, Executive Secretary.
Texas: Lewis Bracy, Secretary-Treasurer.

The Section officers and Section Council are listed on page 12.

Public Health Nursing Samples Wanted—For several years the National Organization for Public Health Nursing, 50 W. 50th St., New York, has been circulating a group of portfolios of samples.

Beautifully prepared, these portfolios have made available selected material classified as printed matter, exhibits, general publicity information, movies, plays and pageants, radio. For revising this collection the N.O.P.H.N. requests samples of

booklets, blotters, bookmarks, newspaper articles, visiting cards, copies of radio talks and playlets, photographs of exhibits, etc.

The portfolio idea is commended to nationals and to state health agencies. In the office, at conventions, and in circulation from city to city such portfolios render a valuable service which cannot be duplicated by any other method.

FOR EDUCATION AND REFERENCE

"Anthraco-Silicosis Among Hard Coal Miners," by U. S. Public Health Service. Supt. of Documents, Washington, D. C. *25 cents.*

"Death Rate for Children Decreases," by J. F. Rogers, M.D. 2 page reprint. Office of Education, Washington, D. C. *Free.*

"Dental Health Week in Delaware," by M. H. Harrington, *Journal*, Dental Hygienists' Assn., 159 Brightwood Ave., Stratford, Conn. Jan., 1936. *25 cents.* Details of radio programs; plays and verses by children.

"The Hard of Hearing," by G. Berry. Revised reprint. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. 4 *Hygeia* pages. *5 cents.*

Irradiated Evaporated Milk Institute, 203 N. Wabash Ave., Chicago, Ill., offers free publications on evaporated milk and its use.

"Pneumonia." Four page folder. New York State Dept. of Health, Albany, N. Y.

"Safety Education Research Survey of the Boston Public Schools." Mimeographed outline of WPA Project 7369. Address John P. Sullivan, Supervisor of Health Education, Boston Public

Schools, 15 Beacon St., Boston, Mass.

"Training of Elementary Teachers for School Health Work," by J. F. Rogers, M.D., Office of Education. Supt. of Documents, Washington, D. C. *5 cents.* 27 pages. A review of what is being done—and not done.

Two reprints on the need for state legislation to require proper labeling of lye and other caustics will be supplied by B. R. Rickards, State Dept. of Health, Albany, N. Y. A section committee of A.M.A. on lye legislation has published its thanks to Mr. Rickards for his effective aid in securing such legislation in New York.

MAGAZINE ARTICLES

"Eyes Right," by Dr. J. H. Kenyon. *Good Housekeeping,* 8th Ave. and 57th St., New York, N. Y. Feb., 1936. *25 cents.* Care of baby eyes.

"Machines Which Imitate Life," by G. W. Gray. *Harpers,* 49 E. 33d St., New York, N. Y. Feb., 1936. *40 cents.* Says the *Journal* (page 307, March, 1936) of this article:

> Is an excellent example of the possibility of putting into plain English a subject as obtruse as biophysics or physical chemistry.

"Safe at School!" by H. Barnsantee. *Rotarian,* 35 E. Wacker Drive, Chicago, Ill. May, 1936. *20 cents.* Teaching important car driving facts in school.

"Prostitution in the Soviet Union," by A. W. Field; "Prostitution in New York City" (editorial contrasting the situation in New York and other cities). *Nation,* 20 Vesey St., New York, N. Y. March 25, 1936. *15 cents.*

"Public Health Nursing," by D. Deming. *Junior League Magazine,* 305 Park Ave., New York, N. Y. May, 1936. *30 cents.* What a public health nurse is, and how volunteers may help.

"Society's Ounce of Prevention," by H. H. Martin. *Junior League Magazine.* May, 1936. Abortion and maternal deaths as reasons for birth control.

"When to Immunize and Why," by Dr. W. W. Bauer. Various diseases of children. *National Parent-Teacher Magazine,* 1201 16th St., N.W., Washington, D. C. May, 1936. *15 cents.*

"You Can't Laugh It Off," by J. Lane. *Collier's,* 250 Park Ave., New York, N. Y. March 21, 1936. What *can* be done about too much fat.

BOOKS AND REPORTS

The Work of the Sanitary Engineer—*By Arthur J. Martin. London: MacDonald and Evans,* 1935. 488 pp., 81 ill. Price, 16 s. net.

"An ample supply of good water, the prompt removal and hygienic disposal of all foul matter—these are the indispensable foundations of healthy life." Ways and means of obtaining these necessities are dealt with by the author under 6 main headings: Part I, Sanitary Administration, 57 pp.; Part II, Water Supply, 130 pp.; Part III, Drainage and Sewerage, 65 pp.; Part IV, Sewage Disposal, 130 pp.; Part V, Collection and Disposal of Refuse, 35 pp.; Part VI, Flood Prevention, Land Drainage and Coast Protection, 25 pp.

This comprehensive handbook covers a broad field in a workman-like manner. The 46 tables of hydraulic and cost data will be found especially convenient in supplementing the more descriptive matter. Historical background is adequately covered and administrative and legal aspects are given deserved weight. To the American sanitary engineer, the book is valuable in giving an excellent general knowledge of English practice. To the sanitary administrator, especially of England, the book is ideally suited. So much of the subject matter is fundamental and is so authoritatively treated that the volume will be of great value to sanitarians of all countries.

Mr. Martin, as a lecturer to students in sanitary science, as an instructor of Army sanitary personnel, and as an examiner of candidates for the Institution of Sanitary Engineers, is well qualified to discuss the sanitary engineer of England. Due to the broad field covered, the discussions of individual subjects are of necessity brief, but the book covers in one volume the essentials of what the sanitary engineer in England and elsewhere should know.

A. M. Buswell
M. LeBosquet, Jr.

Elementary Bacteriology — *By Joseph E. Greaves, M.S., Ph.D. (3rd ed.) Logan, Utah: Utah Agricultural College,* 1936. 562 pp. Price, $3.50.

For this 3rd edition many portions of the original have been rewritten or revised, and several new chapters added. The historical portion is presented in an attractive manner. The main body of the work sets forth the chief characteristics of bacteria, their growth and action. Soil bacteria and their significance are given more prominence than in most textbooks on bacteriology. The description of the relation of these bacteria to food production, industry, and the arts is most interesting. The pathogenic bacteria are described as related to the diseases they cause, also as to means of identification and the general measures to be adopted to destroy or control them.

Improvements might be made by giving definite references, as on pages 233 and 388, for the many quotations inserted, or, as on page 100, by giving a bibliography for each section. It would be well, to be more specific in naming places, such as Charleston, page 488. The reader might suspect it was Charleston, South Carolina, but he might also think of West Virginia.

The author does not indicate the source of the figures presented on pages 477–478. If they are U. S. Census Bureau figures, it would be well

to say so. The author makes a loose use of terms when on page 496, he speaks of "death rates." What he has in mind is fatality rates, though he has given not rates but totals, and his estimate that 10 per cent of all typhoid cases die, is higher than now obtains except in rare outbreaks. As the author says (page 472), "inspection alone cannot be depended upon" to detect bovine tuberculosis. This statement should be taken as a corrective to the picture presented of a tuberculous cow, as most infected animals show no such visible signs as the one pictured. These are minor defects, and do not materially detract from a very interesting book, which is well printed and easily read. A typographical error was noted on page 214, line 32 from the top.

JAMES WALLACE

American Chamber of Horrors—*By Ruth deForest Lamb. New York: Farrar & Rinehart,* 1936. 418 pp. Price, $2.50.

The Food and Drug Administration, the author, and the publisher, by preparing this enlightening text, have performed an important service for the American public. They incidentally illustrate also why food and drug legislation encounters so many obstacles: it tries to cover too much ground.

It seems to the reviewer that food and drug control interests often err in attempting to invoke the cause of public health to justify entirely appropriate activities for the prevention of fraud. Most of the Copeland Bill, for which this book is obviously propaganda, has to do with fraud.

The public health side of this exposé is generally known to public health people, although it is claimed that the inside story of the fight to protect consumers against spray residues is told here for the first time. This book is a dramatic, even startling, presentation of the problem of food and drug control and the serious dangers of many products available to the public. It is accordingly a useful contribution to health education.

The American Medical Association is quoted in regard to two dubious products, but there is no comment on its long and valiant fight in this field. Haven Emerson is quoted as President of the "Public Health Association," and indexed under "Public Health Service."

After reading this book one wonders what might be the fate of a bill designed solely from the standpoint of public health protection and which left to other policing agencies public protection against commercial fraud.

Government represents not only consumers but also producers, manufacturers, and distributors. It is thus handicapped in legislating beyond a certain point wholly and entirely in the interest of consumers, or in protecting buyers against the wiles of sellers who, be it said, are voters also. Organized consumer action is more likely to accomplish this as well as the repeal of such legislation as that which makes it harder to buy clean oleomargarine than dirty butter.

Meanwhile the Chief Educational Officer of the United States Food and Drug Administration has written a thoroughly useful book with informative appendices to add to the growing modern library of political campaign literature.

HOMER N. CALVER

The Algae and Their Life Relations—*By Josephine E. Tilden. Minneapolis: University of Minnesota Press.* 550 pp. Price, $5.00.

This volume by the author of *Myxophyceae of North America and Adjacent Parts* carefully carries the sub-title "Fundamentals of Phycology." Recognizing that reference works dealing with special phases of the

field of phycology are available to the experienced investigator, Miss Tilden has set herself the task of preparing a textbook which includes in a single volume all classes of algae in orderly fashion and answers such broad questions as:

> Are there connecting links between the several classes of algae?
>
> Is there a relationship between the several classes of algae and the higher plants, or between the algae and the primitive or the higher animals?
>
> What is the probable place of origin or point of unusual development of any particular algal group with respect to the geological history of the world?

The book opens with 3 thought provoking chapters (47 pp.) on the history of the evolution of the algae, the distribution of the marine algae in time and space, and the classification of the algae in the light of their evolutionary development. These serve as an introduction to the 5 central chapters of the book which deal with the life histories, morphology and taxonomy of the 5 classes of algae: blue-green (52 pp.), red (106 pp.), brown (120 pp.), yellow-green (16 pp.), and green (120 pp.). The marine organisms receive the largest share of the space. Where the organisms under discussion are of some economic (particularly nutritional) value, the author does not hesitate to elaborate on this aspect of phycology. Three closing chapters consider briefly the problem of algal control and the algae as food for animals and for man (22 pp.). An appendix on how to draw algae for publication, a bibliography, and an index complete the volume.

To the public health engineer who is interested in the relation of the algae to public water supplies, Tilden's book will serve as a useful aid in the identification of genera and species. The excellent discussion of the life cycle of the algae should be of assistance in gaining an understanding of their method of propagation especially in relation to their control. A very direct interest should be the record of poisoning of livestock compelled to drink water-bloom algae. This is given in Chapter IX.

The nutritionist will find much of interest in Miss Tilden's discussion of algae as food for man (Chapter XI) and in her comments upon the manifold possibilities in the utilization of marine algae (Chapters V and VI).

The book is well written and contains excellent illustrations. The printing and binding are good.

GORDON M. FAIR

A Guide to Human Parasitology for Medical Practitioners—*By D. B. Blacklock and T. Southwell (2d ed.). Baltimore: Wood, 1935.* 259 pp. 122 figs. Price, $4.00.

On the basis of its purpose as stated in the title, this is a very useful and satisfactory publication. It has the limitations of any book in which a writer undertakes to condense into 259 pages the large subject of human parasitology. The authors warn the reader that many of the statements are true only of the limited number of parasites with which they deal, are not true of all human parasites in the groups discussed, and are even less often true of the groups as they occur in animals. It might be of value to add to future editions a list of the many parasites not covered.

The writers devote 8 pages to a discussion of the microscope and its use. The reviewer is under the impression that a knowledge of the use of the microscope could be safely predicated for American physicians graduating within the past 20 or 30 years, and hopes that this is not an unwarranted optimism.

The arrangement of the book might be modified to advantage. Thus, Chapter XIII, Examination of Ma-

terial, is placed between a chapter on cestodes and succeeding chapters on cestodes and on other worm parasites; apparently it should precede all other chapters on worm parasites.

There are some grammatical errors, such as *feces* as the subject of a singular verb (p. 24); the frequent displacement of the word *only*, this wording tending to occur too early in an expression, as it customarily does in casual speech (p. 30, *et al.*); errata in cross-references, as in the reference to Fig. 46 on p. 41, which should be to Fig. 47, and the reference on p. 50 to p. 25, which should be to p. 24; the statement that a disease is very fatal, since fatal diseases are not more or less or very fatal (p. 70); certain discrepancies between text figures and descriptions (pp. 75, 76, 77); the statement that the alimentary canal of trematodes consists of a small mouth (p. 139); the habitual use of the terms egg and ovum as different things, contrary to customary usage, without definition of the terms as used (p. 159, *et al.*).

The authors (p, 102, *et al.*) accept the existence of pressure as an explanation for the development of alveolar hydatid, which seems too simple, and the matter is still an open question. The keys are highly variable in form and should be made uniform. In some cases, as on p. 110, species keyed to a number (3) should actually appear as a name (*Hymenolepis nana*) at the point where the number occurs.

The text should be brought up to date in some respects: thus, snail hosts of *Heterophyes heterophyes* (p. 148) have been reported by two workers. The life history of *Strongyloides stercoralis*, as given (p. 168, *et seq.*), indicates an unqualified acceptance of Faust's findings. Without prejudice to Faust, the reviewer believes that his findings require confirmation. The statement (p. 176) that in trichinosis cases the patient dies except in mild infections, needs modification. Patients may either survive or die from severe infections. The statement that *Trichinella spiralis* is rare in man (p. 227) needs modification since from 6 to 27 per cent of cadavers examined in the United States have shown infection. The statement that hydatid is more rarely present in sheep and swine than in cattle and horse (p. 233) runs counter to the fact that in pastoral countries sheep are the customary intermediate hosts of the hydatid tapeworm, and that in the United States swine are the customary intermediate hosts.

Despite the criticisms, the book is a useful publication, covering in a small space a lot of information. Its flaws are of a customary sort and some of its weaknesses are those inherent in any effort at extreme condensation.

M. C. HALL

The True Physician—*By Wingate M. Johnson, M.D. New York: Macmillan,* 1936. 157 pp. Price, $1.75.

This charming and useful book is the outcome of fatherly advice given to the graduating class of Duke Medical School. The talk was so well received that the author has expanded it to make the present volume, which is delightfully written and contains a wealth of worldly as well as spiritual wisdom.

It is hard to select one chapter for praise over others, but the reviewer wishes to commend Chapter XII, in which is given a list of books which the author has found of greatest value to himself, and which he advises medical men generally to read. We are somewhat surprised as well as sorry not to see the *Medical Essays of Oliver Wendell Holmes* included.

The book is well printed and can be unreservedly commended to those just entering the profession as well as to the older members. MAZŸCK P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Life Expectancy in England—Increases in the British life table during the past three decades will prove an interesting check on our own. At birth, the expectancy for males has increased during these 30 years, 50, 51, 58 years, and for females 55, 59, 62 (decimals omitted).

ANON. English Life Table No. 10. Pub. Health. 49, 7:242 (Apr.), 1936.

Smallpox Study—Among a representative population sample of 8,700 families only about one-fifth of the children had been vaccinated before school (65 per cent of the adults had been vaccinated). Of the 17 cases of smallpox observed, 16 occurred in unvaccinated persons, one had been vaccinated 40 years previously.

COLLINS, S. D. History and Frequency of Smallpox Vaccinations and Cases in 9,000 Families. Pub. Health Rep. 51, 16:443 (Apr. 17), 1936.

Chronic Disease—Among the benefits to be anticipated from the house-to-house survey conducted in 95 communities, covering a population of 3 million is a true picture of the chronic disease situation. Only when the problem is realized will there be an impetus toward a unified effort for its correction.

CUMMING, H. S. Chronic Disease as a Public Health Problem. Milbank Quarterly. 14, 2:125 (Apr.), 1936.

Preventing Heart Disease Deaths—There is a real as well as an apparent increase in coronary disease, says this student of public health, and to prevent further inroads an educational campaign is needed to teach daily exercise as one of the essential health habits.

DENNY, F. P. The Increase in Coronary Disease and Its Cause. New Eng. J. Med. 214, 16:769 (Apr. 16), 1936.

Our Insanitary Cities—About half the major cities of New England and Middle Atlantic states make some pretense at treating sewage, the rest are content to pollute streams and nearby tide water. All the important rivers of the section are polluted in different degrees. What a record!

ELLSWORTH, S. M. Sanitation in the North Atlantic States. Municipal Sanitation. 7, 4:132 (Apr.), 1936.

For All to Read—Truly this man has "the gift of tongues"! One of the best examples of the way to present a health administrative concept. It should be pondered over by every health worker. It happens to be about public health nursing, but there is meat in it for everyone.

HAGGARD, H. W. Who Owns Health? Pub. Health Nurs. 28, 4:214 (Apr.), 1936.

Matches and Gunpowder—If and when migration from Mexico and elsewhere is resumed, then look out for trouble, for there may be plenty when the virus of malignant smallpox is reimported into a population as innocent of vaccination as is ours. The prompt publication of smallpox deaths is essential to public safety. This is an important contribution to epidemiologic literature.

HEDRICH, A. W. Changes in the Incidence and Fatality of Smallpox in Recent Decades. Pub. Health Rep. 51, 14:363 (Apr. 3), 1936.

Another Bugbear Ready for Interment—In round numbers, the upstate New York births per 1,000 foreign born mothers (standardized

rates) have declined one-half, to a rate of 115, whereas the births among native mothers have declined only one-quarter, to 107 (all between the years 1920 and 1934). That so small a difference in birth rates would ever exist between native and foreign born mothers would have been considered ridiculous a generation ago.

KISER, C. V. Recent Trends in Birth Rates among Foreign and Native White Married Women in Up-State New York. Milbank Quarterly. 2:173 (Apr.), 1936.

Health Problems Created by Machines—Not a pretty, but a realistic picture of the industrial past is painted. We are wont to praise the past, underrate the present, and be anxious for the future. We must have faith, concludes the author, in the ability of each age to solve its problems and to rectify its mistakes.

OLIVER, T. Our Mechanistic Age. J. State Med. 54, 4:191 (Apr.), 1936.

The Answers Being Self-Evident!—In the 8 counties studied, the population in thousands per nurse varied from 5 to 35 (1 nurse per 2,000 being the standard to be reached some day!). As was to be expected, as the nurse spreads her services out thinner and thinner, the amount of effective educational work she can do per family becomes by the same token less and less. The paper closes with the very rhetorical question: Is it true economy to continue to give service to only a few rural families?

RANDALL, M. G. How Much Work Can a Rural Nurse Do? Milbank Memorial Quarterly. 14, 2:163 (Apr.), 1936.

Statesmanship in Public Health—After having commented upon a couple of thousand papers on health, the reviewer's eye easily becomes jaundiced, but there is yet hope when the spirit can rise to a statesmanlike presentation of the larger objectives in public hygiene. This is just that kind of a paper.

PARRAN, T., JR. Health Security. Milbank Quarterly. 14, 2:113 (Apr.), 1936.

Venereal Delinquents—Follow-up of delinquent venereal cases as practiced by the Baltimore Health Department is described; it should encourage other health departments to go and do likewise.

REINHARD, F. O., and FALES, W. T. Delinquent Patients in Venereal Disease Clinics. J.A.M.A. 106, 16:1377 (Apr. 18), 1936.

ASSOCIATION NEWS

HEALTH CONSERVATION CONTESTS FOR 1935

THE Chamber of Commerce of the United States at its Annual Meeting in Washington, D. C., April 27, distributed the annual awards to the first place cities and counties in the City and Rural Health Conservation Contests, conducted by that Chamber and the American Public Health Association. The cities and counties receiving honorable mention in their respective population groups and geographical divisions were named and it was announced that the diplomas awarded them would be forwarded at a later date. The awards to the first ranking cities and counties are handsome plaques. Four special awards were given to four cities which, having won a first award twice, are placed in a special group and are given a diploma provided the previous high record in health work has been maintained.

The newly appointed Surgeon General of the U. S. Public Health Service, Thomas Parran, M.D., made the presentations, Harper Sibley of Rochester, N. Y., President of the National Chamber, being in the chair.

The following is the list of winners for 1935:

CITY CONTEST

Group I

First Award	*Honorable Mention*
Detroit, Mich.	Milwaukee, Wis. Pittsburgh, Pa.

Group II

First Award	*Honorable Mention*
Oakland, Calif.	Minneapolis, Minn. Dallas, Tex.

Group III

First Award	*Honorable Mention*
Syracuse, N. Y.	New Haven, Conn. Springfield, Mass. Grand Rapids, Mich. Reading, Pa. Honolulu, Hawaii Hartford, Conn. Duluth, Minn. Yonkers, N. Y. Tacoma, Wash.

Group I—Cities of over 500,000 population
" II—Cities of 250,000 to 500,000 population
" III—Cities of 100,000 to 250,000 population
" IV—Cities of 50,000 to 100,000 population
" V—Cities of 20,000 to 50,000 population
" VI—Cities under 20,000 population

Group IV

First Award	*Honorable Mention*
Schenectady, N. Y.	Pasadena, Calif. Evanston, Ill. Waterbury, Conn. New Rochelle, N. Y. Kalamazoo, Mich. Greensboro, N. C. Binghamton, N. Y. Sacramento, Calif. Saginaw, Mich.

Group V

First Award	*Honorable Mention*
Brookline, Mass.	Auburn, N. Y. Greenwich, Conn. Watertown, N. Y. Santa Barbara, Calif. Pittsfield, Mass. Plainfield, N. J. Ithaca, N. Y.

Group VI

First Award	*Honorable Mention*
Hibbing, Minn.	Englewood, N. J. Blackwell, Okla. Miami Beach, Fla.

Cities obtaining special diplomas: Baltimore, Md., Hackensack, N. J., Newark, N. J., and Palo Alto, Calif.

RURAL CONTEST

Northeastern Division

First Award	*Honorable Mention*
Westchester Co., N. Y.	Cattaraugus Co., N. Y. Southern Berkshire District, Mass. Cortland Co., N. Y. Ottawa Co., Mich. Richland Co., Ohio

Eastern Division

First Award	*Honorable Mention*
Davidson Co., Tenn.	Kent Co., Md. Forsyth Co., N. C. Fayette Co., Ky. Sullivan Co., Tenn. Rutherford Co., Tenn. Wicomico Co., Md. Madison Co., Ky. Shelby Co., Tenn.

Southeastern Division

First Award	*Honorable Mention*
Glynn Co., Ga.	Pike Co., Miss. Charleston Co., S. C. Lauderdale Co., Miss.

North Central Division

First Award	*Honorable Mention*
Shawnee Co., Kans.	No honorable mention was given in this division.

South Central Division

First Award	*Honorable Mention*
El Paso Co., Tex.	Dallas Co., Tex. Nolan Co., Tex. Potter Co., Tex. Rapides Parish, La.

Western Division

First Award	*Honorable Mention*
Santa Barbara Co., Calif.	Los Angeles Co., Calif. Santa Clara Co., Calif. Spokane Co., Wash.

In making the presentations, Dr. Parran took occasion to emphasize the special opportunities for advancement in public health work at the present time, the marked interest being shown in health betterment by business men, and the necessity of even the best organized cities and counties making further progress, as the obtaining of an award was not to lead to self complacency, because the awards did not signify perfection, but were to be regarded as incentives and stimulants for higher attainments.

ADDENDUM

In connection with the Rural Contest for 1936 attention is called to the recent provision made by the Contest Committee to enable every county and district with full-time health service to participate. Health units having within their bounds a chamber of commerce or business organization which has membership in the National Chamber of Commerce at Washington are as heretofore to be enrolled by their local business group. Those units which have no such business group to sponsor them may enroll through the Committee on Administrative Practice of the American Public Health Association.

COMMITTEE ON THE HYGIENE OF HOUSING

A NEW committee of the Association has been created to be known as the Committee on the Hygiene of Housing. Abel Wolman, Chairman of the Committee on Research and Standards, appointed the committee with the knowledge of the Executive Board and Prof. C.-E. A. Winslow of Yale University is Chairman. Other members of the committee include R. H. Britten, Senior Statistician, U. S. Public Health Service, Washington, D. C.; A. R. Clas, Director of Housing, Federal Emergency Administration of Public Works; Col. J. I. Connolly of the Chicago Department of Health; Robert L. Davison, Director of Housing Research, John B. Pierce Foundation, New York, N. Y.; J. Andre Fouilhoux, architect, New York, N. Y.; Greta Gray, University of Southern California, Los Angeles, Calif.; James E. Ives, Ph.D., Senior Physicist, U. S. Public Health Service, Washington, D. C.; and H. A.

Whittaker, Sanitary Engineer, State Department of Health, Minneapolis, Minn.

This committee was set up in conformity with a request from Frank G. Boudreau, M.D., of the Health Section of the League of Nations, Geneva, and will serve as a committee of reference in the United States for the coöperative work of the Health Section on housing.

At the first meeting of this committee held in New York on May 15, Mr. Britten was appointed Secretary, and each member representing some special aspect of the housing problem was asked to prepare a memorandum on his subject which could be circulated for a preliminary statement of objectives in order that basic minimum but adequate standards for housing could be set up on a scientifically planned basis. The committee has in mind a long range scheme for promoting the hygiene of housing and it is probable that several other phases of the subject will be represented in the committee as finally constituted.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

David H. Andrew, M.D., Wytheville, Va., County Health Officer

Charles J. Ball, 211 City Hall Annex, New Orleans, La., Assistant Superintendent of Public Health

Adrian L. Carson, Jr., M.D., Fairfax, Va., County Health Officer

Wallace M. Chapman, M.D., 204 Liberty, Glasgow, Ky., Director, Barren County Health Dept.

Karl C. Eberly, M.D., 310 Wayne Pharmacal Bldg., Fort Wayne, Ind., Director, Dept. of Public Health

George M. Fraser, M.B., City Bldgs., Peterborough, Ont., Canada, Medical Officer of Health

Shockley, DeW. Gardner, M.D., Valley Health District, Harrisonburg, Va., Health Officer

Roy T. Hansen, M.D., 7608 W. State St., Wauwatosa, Wis., City Health Commissioner

George W. Hemmeter, M.D., 3002 Garrison Blvd., Baltimore, Md., Health Officer, Western Health District, City Health Dept.

James A. Henderson, M.D., 624 Maison Blanche, New Orleans, La., Chief Sanitary Officer, City Board of Health

Jacob H. Landes, M.D., 590 E. 138 St., New York, N. Y., Supervisor, Bureau of School Hygiene, New York City Dept. of Health

Hugh C. McRee, M.D., Opelika, Ala., County Health Officer

C. H. Munger, M.D., Emporia, Kans., County Health Officer

Byron F. Porter, M.D., Caribou, Me., District Health Officer

Jacob Rosenbluth, M.D., 356 E. 8th St., New York, N. Y., Chief Diagnostician, New York City Dept. of Health

Wallace W. Ryall, M.D., City Bldg., Youngstown, O., Commissioner of Health

Charles L. Savage, M.D., c/o Miss Verna Routh, Lebanon, Va., Health Officer

Mack I. Shanholtz, M.D., Dept. of Health, Bristol, Va., Health Officer

Bert L Stinson, M.D., New Iberia, La., Director, Iberia Parish Health Unit

Laboratory Section

Vera M. Crossley, 80 Lawton Blvd., Toronto, Ont., Canada, Assistant Bacteriologist, Ontario Dept. of Health

Dan R. Gonzalez, 2900 Blanche St., Pasadena, Calif., Director of Laboratory, Las Encinas Sanitarium

Mattie P. Henderson, 1502 E. Fifth Ave., Knoxville, Tenn., Laboratory Technician, Tennessee Valley Authority

John F. Kessel, School of Medicine, University of Southern California, Los Angeles, Calif., Professor of Bacteriology

William H. Potts, D.V.M., Health Dept., Goldsboro, N. C., Milk and Food Inspector, Wayne County Health Dept.

Philip Reichert, M.D., 4 E. 88 St., New York, N. Y., Director of Clinical Laboratory 527, New York City Dept. of Health

Charles R. Rein, M.D., 580 Fifth Ave., New York, N. Y., Consulting Serologist, U. S. Public Health Service

Frank W. Schofield, D.V.S., College Heights, Guelph, Ont., Canada, Professor of Bacteriology, Ontario Veterinary College

Jesse W. Stevens, 616 E. Grove St., Ontario, Calif., Bacteriologist, Research Dept., California Fruit Growers Exchange

Luther Thompson, Ph.D., Mayo Clinic, Rochester, Minn., Laboratory Diagnosis of Communicable Diseases
Martha E. Thompson, State Cooperative Laboratory, Superior, Wis., Director
Wyeth S. Wallace, Box 47, Sheffield, Ala., Field Medical Technician, Tennessee Valley Authority
Maurice W. Yale, Ph.D., New York Agr. Exp. Station, Geneva, N. Y., Associate in Research

Vital Statistics Section

Clara E. Councell, 2411 N. Charles St., Baltimore, Md., Statistician, Bureau of Vital Statistics, State Dept. of Health
Clark Tibbitts, 153 E. Elizabeth St., Detroit, Mich., Field Director, U. S. Public Health Service Health Inventory

Public Health Engineering Section

John B. Belknap, State Dept. of Health, Gouverneur, N. Y., District Sanitary Engineer
John E. Kiker, Jr., 611 Professional Bldg., Baltimore, Md., Chemical and Sanitary Engineer
Harry A. Faber, 50 E. 41 St., New York, N. Y., Sanitary Engineer, Chlorine Institute, Inc.
John M. Henderson, C.E., P. O. Box 344, Brunswick, Ga., Division Engineer, State Dept. of Health
Harry C. Kneeland, 51 S. Jackson St., Pittsburgh, Pa., Technical Supervision of Swimming Pools and Water Works
Howard W. Lundy, 285 Brookline, Cambridge, Mass., Candidate for Doctor of Public Health Degree, Massachusetts Institute of Technology
Alexander H. Zimmerman, 5147 N. St. Louis Ave., Chicago, Ill., Ventilation Engineer, Board of Health

Industrial Hygiene Section

P. Wilcox Gumaer, 25 Garden St., West Englewood, N. J., Consulting Engineer—prevention of occupation diseases
Frederick S. Mallette, 169 S. Grove St., Ypsilanti, Mich., Supervisor, Plant Survey Interpretation, U. S. Public Health Service
O. A. Sander, M.D., 710 N. Plankinton Ave., Milwaukee, Wis., Industrial Physician

Food and Nutrition Section

Bertrand E. Bennison, 54 Marion St., Brookline, Mass., Student, Massachusetts Institute of Technology
Henry J. Rugo, 321 Norfolk Ave., Dorchester, Mass., Student, Massachusetts Institute of Technology

Child Hygiene Section

Marion W. Caskey, M.D., Ph.D., Taylorsville, Ky., Director of Health, Spencer County
Prescott T. Hill, M.D., 225 Broad St., Providence, R. I., Medical Inspector, Public Schools

Public Health Education Section

Clifford H. Bowman, P. O. Box 916, Hilo, Hawaii, Division Supervisor, Bureau of Sanitation, Board of Health, Territory of Hawaii
Alejandro Casuso, M.D., Malecon 250, Havana, Cuba, Professor of Hygiene, Medical School, University of Havana
John R. MacElroy, M.D., Jonesville, N. Y., Health Officer
Donald J. MacGillivray, M.D., 4 Lyndhurst St., Dorchester Centre, Mass., formerly Health Officer, Portland, Conn.
Albert B. McCreary, M.D., Eastville, Va., Director, Northampton Health Unit
William M. Randolph, M.D., Route 2, Charlottesville, Va., Clinician, Out-Patient Tuberculosis Service, State Dept. of Health
Robert E. Schneider, M.S.P.H., 81 Marlboro St., Waterbury, Conn., Teacher of Health Education, Schenectady, N. Y., Public Schools

Public Health Nursing Section

Ichiyo Nakamaru, P. O. Box 184, Pahala, Kau, Hawaii, Public Health Nurse, Board of Health, Territory of Hawaii
Mary E. Smith, R.N., Bureau of Public Health, Santa Fe, N. Mex., Superintendent, Public Health Nursing
Gladys V. Solveson, R.N., Western Navajo Area, Tuba City, Ariz., Field Nurse, U. S. Indian Service
Hazel J. Tucker, R.N., 1027 Lincoln Ave., Toledo, O., Supervisor of WPA Nutrition and Health Clinic

Epidemiology Section

Joaquin Fernandez y Melendez, Apartado 157, Habana, Cuba, Director de Campo de la Comision de Malaria de Cuba
Percy T. Watson, M.D., Box 215, Cass Lake, Minn., Local Medical Director, Chippewa Health Unit, State Board of Health

Unaffiliated

B. Russell Franklin, C.P.H., 43 Highland Ave., Ayer, Mass., Milk and Sanitary Inspector, Nashoba Associated Boards of Health
Frederick Schultz, Box 3378, Honolulu, T. H., Division Supervisor, Bureau of Sanitation, Board of Health, Territory of Hawaii

Nelson K. Spencer, Board of Health, Honolulu, T. H., Sanitary Inspector
John W. K. Wright, Territorial Board of Health, Honolulu, T. H., Senior Agricultural Aide

DECEASED MEMBERS

Robert B. Morse, Hyattsville, Md., Elected Member 1915, Fellow 1922
C. N. McCloud, M.D., St. Paul, Minn., Elected Member 1919
Carl A. Nowak, St. Louis, Mo., Elected Member 1932
James S. Walton, M.D., Amsterdam, N. Y., Elected Member 1935
Jules Constantin, M.D., D.P.H., Roberval, P. Que., Elected Member 1933
Gertrude M. DeWitt, Chicopee, Mass., Elected Member 1920
Andronique Lafond, M.D., D.P.H., Parisville, P. Que., Canada, Elected Member 1933
Leslie Wentzel, Scranton, Pa., Elected Member 1922
Roger G. Perkins, M.D., Wakefield, R. I., Elected Member 1902, Fellow 1922, Life Member 1929
Edgar Sydenstricker, New York, N. Y., Elected Member 1917, Fellow 1922
Joseph B. Garlick, M.D., Schenectady, N. Y., Elected Member 1935.

CLOSING DATE FOR FELLOWSHIP APPLICATIONS

THE Committee on Fellowship and Membership wishes to announce that September 1 is the closing date for accepting Fellowship applications for action at the New Orleans Annual Meeting. Eligible members who desire to apply for Fellowship this year are requested to submit their applications to the committee as much in advance of September 1 as possible.

SCIENTIFIC EXHIBITS IN NEW ORLEANS

EXCELLENT accommodations for exhibits has been promised by the Association Committee on Scientific Exhibits for the 65th Annual Meeting of the American Public Health Association in New Orleans, October 20–23. The local committee has been active, and under the leadership of Dr. Joseph R. D'Aunoy, the number and kinds of exhibits are expected to exceed last year's. Exhibits have been promised by the U. S. Public Health Service and the U. S. Children's Bureau. Health problems peculiar to the South will receive special attention and, in addition, an unusual exhibit on leprosy will be included.

One of the excellent features of the scientific exhibits in Milwaukee was the group of laboratory exhibits secured by the special Laboratory Section committee on exhibits under the direction of Dr. Fred O. Tonney. Following this experience, the other Sections of the Association have been requested to designate similar representatives to assure a representative scope of exhibits. Four Sections have made these appointments:

Industrial Hygiene—Bernard S. Coleman
Laboratory—Fred O. Tonney, M.D.
Engineering—A. H. Fletcher
Public Health Nursing—Marguerite A. Wales

The efforts of these individuals will bear fruit next October in a larger assortment of exhibits from each of these fields as well as in special exhibits of general interest. It is expected that other Sections will designate representatives to assure representation of their fields in the Scientific Exhibits.

Exhibitors this year will receive citations of merit not only on a basis of exhibit content but also on method of presentation.

Exhibit information blanks will be sent on request to the Committee on Scientific Exhibits, American Public Health Association, 50 West 50th Street, New York, N. Y.

NEWS FROM THE FIELD

NEW MEXICO MEETING

THE Annual Meeting of the New Mexico Public Health Association, in joint session with the Medical Society of New Mexico, was held in Carlsbad, N. M., May 6–8, under the presidency of Elroy F. McIntyre, M.D., member A.P.H.A., Health Officer of Santa Fe.

Among the speakers from outside the state were: Karl F. Meyer, Ph.D., member A.P.H.A., of San Francisco; W. W. Bauer, M.D., F.A.P.H.A., of the American Medical Association, Chicago; Thomas J. McCamant, M.D., member A.P.H.A., Health Officer of El Paso, Tex.; and Reginald M. Atwater, M.D., Executive Secretary of the American Public Health Association.

Officers for the coming year were elected as follows:

President: James R. Scott, M.D., F.A.P.H.A., Albuquerque
Vice-President: Emma S. Maylor, R.N., member A.P.H.A., Fort Sumner
Secretary-Treasurer: Paul S. Fox, C.E., F.A.P.H.A., Santa Fe

The program included special consideration of undulant fever as it appears in the Southwest, as well as problems of tuberculosis, trachoma, meningitis, and public health education, and included several phases of malaria control.

GORGAS ESSAY WINNER

HELEN COLLENTINE, Messmer High School, Milwaukee, Wis., was awarded the prize of $500 and a trip to Washington for her essay on "Gorgas' Control of Transmissible and Other Preventable Diseases." Bronze medals were awarded for the best essay in each high school.

A new contest will be opened next October. For information write to Gorgas Memorial Institute, Washington, D. C.

THIRD PAN AMERICAN CONFERENCE OF NATIONAL DIRECTORS OF HEALTH

THE Third Pan American Conference of National Directors of Health held its sessions in Washington, D. C., April 6 to 13. The following delegates were in attendance:

Argentina, Dr. Miguel Sussini; Brazil, Dr. João Barros Barreto; Chile, Dr. Víctor Grossi; Colombia, Dr. Enrique Torres; Costa Rica, Dr. Solón Núñez, Dr. Mariano Rodríguez Alvarado; Cuba, Dr. Domingo Ramos; Dominican Republic, Dr. Rafael Espaillat de la Mota; Guatemala, Lic. Enrique López Herrarte; Haití, Dr. Rulx León; México, General José Siurob, M.D., Dr. Ernesto Cervera, Dr. Gerardo Varela; Nicaragua, Dr. Emigdio Lola; Perú, Dr. Carlos Monge; United States, Dr. Hugh S. Cumming, Dr. Thomas Parran, Dr. F. A. Carmelia, Dr. W. L. Treadway, Dr. R. C. Williams, Dr. John D. Long, Dr. Bolívar J. Lloyd, Dr. George W. McCoy, Dr. J. P. Leake, Dr. C. L. Williams, Dr. L. L. Williams, Dr. J. W. Mountin; Uruguay, Dr. Justo F. González; Venezuela, Dr. Arnoldo Gabaldon.

The subjects discussed were as follows: Coördination of Policies and Activities of Federal, State and Municipal Departments of Health; Appropriations for Health Work, Allocations of Funds; Yellow Fever; Tuberculosis, Vaccines; Amebiasis and Bacillary Dysenteries; Vital Statistics;

School and Industrial Hygiene; Modern Trends in Public Health; The Narcotic Problem; Maternal and Child Welfare; Rural Sanitation; The Venereal Diseases; Nutrition; Bubonic Plague; Poliomyelitis; Milk and its Relation to the Public Health; Trachoma and Onchocerciasis; Quarantine Measures; Life in High Altitudes; Leprosy; Malaria.

SUMMER SIGHT SAVING CLASSES

THE National Society for the Prevention of Blindness has announced that courses for the training of teachers and supervisors of sight-saving classes will be offered at the 1936 summer sessions of the following:

University of Cincinnati, Cincinnati, Ohio—June 22–July 28.

University of California at Los Angeles, West Los Angeles, Calif.—June 27–Aug. 7.

State Normal School, Oswego, N. Y.—June 29–Aug. 7. Course to be given in Syracuse, N. Y.

Teachers College, Columbia University, New York, N. Y.—July 7–August 14.

Details regarding the courses may be obtained from the university or college.

A.M.A. ELECTS NEW PRESIDENT

AT the meeting of the American Medical Association in Kansas City, Mo., May 11–15, the House of Delegates authorized Dr. James S. McLester, of Birmingham, Ala., President, to announce Dr. J. Tate Mason of Seattle, Wash., President-Elect, as the new President, without the usual installation ceremonies, due to the critical illness of Dr. Mason. Dr. McLester will act as President for the present. Dr. John H. J. Upham, of Ohio State University, was made President-Elect. Dr. Charles Gordon Heyd, Professor of Surgery, Post-Graduate Medical School and Hospital, New York, was elected Vice-President.

The Meeting was considered one of the best the American Medical Association has held. There were many good papers, especially on encephalitis and poliomyelitis. The scientific exhibits were truly marvelous.

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

THE Public Health Association of New York City was organized on May 18 at a meeting in the Department of Health. Made up entirely of New York City members of the American Public Health Association, the new organization aims to bring this group into closer contact with the activities of the parent Association, to encourage the scientific advancement of its members in the field of public health and to aid the development of the public health movement in this city.

Officers elected were:

President—Donald B. Armstrong, M.D.
1st Vice-President—John L. Rice, M.D.
2nd Vice-President—Hazel Corbin
Secretary-Treasurer—Frank Kiernan

George T. Palmer, Dr.P.H., Deputy Commissioner of Health of the City of New York and chairman of the organization Committee, said:

The need for a local affiliated branch of the American Public Health Association has been strongly urged by many leading public health workers in New York City. The American Public Health Association has 5,000 members and these are distributed over the United States, Canada, Mexico, and Cuba. One-tenth, or nearly 500 of its membership, is located in New York City. Problems arise in this great metropolitan center which demand a closer understanding and exchange of viewpoints among public health workers in the official agencies, the schools, the medical, engineering, social welfare, and other scientific bodies in the city. This new organization will make this possible. Then there comes the question of the Annual Meetings of the parent Association which are often held at long distances. The New York local chapter of the A.P.H.A. will provide an opportunity for local conferences similar to those held annually by the New York State Health Officers at Saratoga Springs. Experience in various parts of the country prove

such regional meetings eminently successful, and the New York City chapter will, it is hoped, fill a long felt need.

New York City was the birthplace of the American Public Health Association, the organization taking place on September 12, 1872. Dr. Stephen Smith, an outstanding public health authority and usually regarded as the father of the present Department of Health, was its first President.

PERSONALS

ALFRED G. LONG, M.D., F.A.P.H.A., former Director of the Diagnostic Laboratory, Maine State Board of Health, has been appointed Director of Laboratories for the Good Samaritan and Howard County Hospitals, Kokomo, Ind.

LAWRASON BROWN, M.D., F.A.P.H.A., Consulting Physician, Trudeau Sanatorium, Saranac Lake, N. Y., will be awarded the honorary degree of Doctor of Science by the Medical College of Virginia, Richmond, Va., at their commencement exercises on June 2.

DR. HARRY G. SOUTHARD, of Marysville, Ohio, formerly State Health Director, has been appointed Health Officer of Union County, to succeed Dr. John D. Boylan, of Milford Center (incorrectly stated as of Noble County in the April issue, page 453).

DR. BENJAMIN SCHWARTZ has been appointed Chief of the Zoölogical Division of the Bureau of Animal Industry, U. S. Department of Agriculture. Dr. Schwartz, who has been Assistant Chief of that Division since 1932, succeeds Dr. Maurice C. Hall, now with the National Institute of Health, of the Treasury Department, Washington, D. C.

DR. HOWARD B. METTEL, of Indianapolis, Ind., has been appointed Director of the Department of Child and Maternal Health of the Indiana State Division of Public Health.

DR. JOHN W. DUGGER, of Jackson, Miss., has been named Director of the Pearl River County Health Unit, succeeding Dr. George E. Godman, of Poplarville, resigned.

DR. J. W. MORELAND, of Carpio, N. Dak., has been appointed Health Officer of Ward County, succeeding Dr. Henry L. Halverson, of Minot, resigned.

DR. THOMAS M. PARKINS, of Staunton, Va., has been appointed Health Officer to succeed Dr. James Fairfax Fulton.

DR. ETHAN B. PFEFFERKORN, of Oshkosh, Wis., has been appointed Assistant State Health Officer, to succeed Dr. Guy W. Henika, of Madison.

KENNETH F. MAXCY, M.D., Fellow A.P.H.A., of the University of Virginia, University, Va., has been appointed, by the Board of Regents of the University of Minnesota, Professor and head of the Department of Preventive Medicine and Public Health of the University of Minneapolis. Dr. Maxcy will assume his duties during the coming summer.

ELSBETH H. VAUGHAN, R.N., Fellow A.P.H.A., of St. Louis, Mo., was presented with the Florence Nightingale Medal by Admiral Carey T. Grayson, in recognition of outstanding nursing service, at the annual meeting of the American Red Cross, in Chicago in May.

HENRY GRADY CALLISON, M.D., F.A.P.H.A., Commissioner of Health of Richmond County, Ga., since 1933, has accepted a position as Director of the field training unit personnel of the South Carolina State Department of Health, with offices at Columbia, S. C. Dr. Thomas B. Phinizy is Acting Commissioner.

CONFERENCES AND DATES

June 4–6, American Dermatological Association, Swampscott, Mass.
June 5, 6, Eleventh Annual Meeting of the New England Health Education Association, Massachusetts Institute of Technology, Cambridge, Mass.
June 6–Nov. 29, Medical Exhibit, "Story of Life," in Texas Centennial Exposition, Dallas, Tex.
June 8–12, Annual Convention of American Water Works Association, Hotel Biltmore, Los Angeles, Calif.
June 9–12, National Conference on Weights and Measures, Bureau of Standards, Washington, D. C.
June 10, Spring Meeting of the New York State Sewage Works Association, Lido Beach, L. I., N. Y.
June 11–12, Annual Meeting, Illinois Association of Sanitary Districts, Fox Hotel, Elgin, Ill.
June 12–13, Annual Convention, Pennsylvania Association of Planning Commissioners, Williamsport, Pa.
June 15–Aug. 21, Speech Conference, University of Denver, Denver, Colo.
June 16–18, Tenth Iowa Conference on Child Development and Parent Education, Iowa City, Iowa.
June 20–26, Canadian Medical Association, Victoria, B. C.
June 21–26, Biennial Convention of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing, Los Angeles, Calif. Headquarters will be, respectively: A.N.A., and N.L.N.E., Ambassador Hotel; N.O.P.H.N., Biltmore Hotel.
June 22–23, Conference of State and Provincial Health Authorities of North America, Vancouver, B. C.
June 22–25, National Conference on Visual Education and Film Exhibition (DeVry Foundation). Francis W. Parker School, Chicago, Ill.
June 22–25, Annual Meeting of the National Association of Master Plumbers, Hotel Statler, Buffalo, N. Y.
June 23–25, Annual Conference of Health Officers and Public Health Nurses, Saratoga Springs, N. Y.
June 24–26, Annual Conference, Pennsylvania Sewage Works Association, State College, Pa.
June 24–26, Annual Convention of Union of Alberta Municipalities, Lethbridge, Alta., Canada.
June 24–27, Seventh Annual Meeting, Western Branch, A.P.H.A.—meeting simultaneously with Canadian Public Health Association—Vancouver and Victoria, B. C. Hotel Vancouver.
June 26–27, Annual Meeting, New England Association of Commercial Executives, Pittsfield, Mass.
June 27–July 2, National Education Association, Portland, Ore.
June 28–July 2, Annual Meeting, National Education Association of the United States, Portland, Ore.
July, Third International Conference on Social Work Problems, London.
July 6–10, 29th Annual Meeting of the American Home Economics Association, Olympic Hotel, Seattle, Wash.
July 6–11, The Royal Sanitary Institute, Southport, England.
July 13–17, American Dental Association, San Francisco, Calif.
July 18–23, Third International Open Air School Congress, Bielefeld and Hanover, Germany.
July 25–Aug. 1, The Second International Congress of Microbiology, London.
July 27–29, Annual Meeting, Union of Canadian Municipalities, Vancouver, B. C.
Aug. 2–8, Annual Meeting, National Institute for Commercial and Trade Organization Executives, Northwestern University, Evanston, Ill.

Aug. 11–14, American Veterinary Medical Association, Deshler-Wallick Hotel, Columbus, O.

Aug. 16–22, National Hospital Association, Philadelphia, Pa.

Aug. 16–22, National Medical Association, Philadelphia, Pa.

Aug. 19–21, Annual Meeting—Central States Section, American Water Works Association, Hotel Cleveland, Cleveland, Ohio

Aug. 31–Sept. 12, Harvard Tercentenary Conference of Arts and Sciences, Cambridge, Mass.

Sept. 7–10, International Union Against Tuberculosis, Lisbon, Portugal.

Sept. 15–30, First International Congress of Sanatoria and Private Nursing Homes; Margitsziget, Sanatorium, Budapest, Hungary.

Sept. 21–23, Annual Convention, American Institute of Park Executives and the American Park Society, South Bend, Ind.

Sept. 22–25, Annual Meeting—New England Water Works Association, Pennsylvania Hotel, New York, N. Y.

Sept. 23–25, Annual Meeting of the New York State Association of Dairy and Milk Inspectors, Van Curler Hotel, Schenectady, N. Y.

Sept. 28–30, Public Works Congress—American Society of Municipal Engineers—International Association of Public Works Officials, Toronto, Ont.

Sept. 28–Oct. 2, American Hospital Association, Cleveland, O.

Sept. 29–Oct. 3, First International Conference on Fever Therapy, Columbia University, New York, N. Y.

Oct. 5–9, Annual Safety Congress and Exposition, National Safety Council, Atlantic City, N. J.

Oct. 10–18, National Dairy Show, Dallas, Tex.

Oct. 12–15, Annual Convention—Southwest Section, American Water Works Association, Fort Smith, Ark.

Oct. 12–17, The Dairy Industries Exposition, Atlantic City, N. J.

Oct. 12–18, Third International Congress on Malaria, Madrid, Spain.

Oct. 17–25, Centennial Exposition Dairy Show, Atlantic City, N. J.

Oct. 19–21, Annual Meeting, International City Managers' Association, Richmond, Va.

Oct. 20–23, Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Oct. 20–23, American Association of School Physicians, Hotel Roosevelt, New Orleans, La.

Oct. 21–23, Ontario Hospital Association, Toronto, Ont.

Oct. 26–28, Annual Meeting—Missouri Valley Section, American Water Works Association, Kansas City, Mo.

Oct. 26–28, National Association of Exterminators & Fumigators, Cleveland, Ohio.

Oct. 29–31, Annual Meeting of the Association of Military Surgeons, Detroit, Mich.

Nov. 8–11, Annual Meeting, National Association of Commercial Organization Secretaries, Omaha, Nebr.

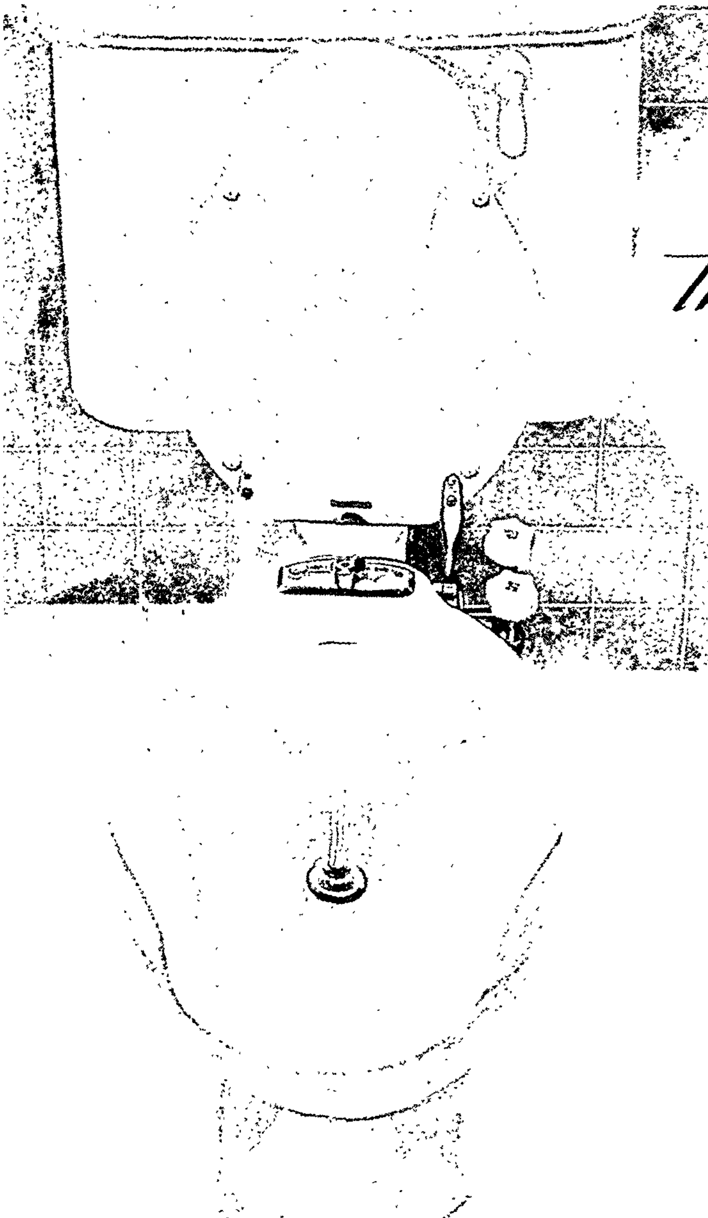
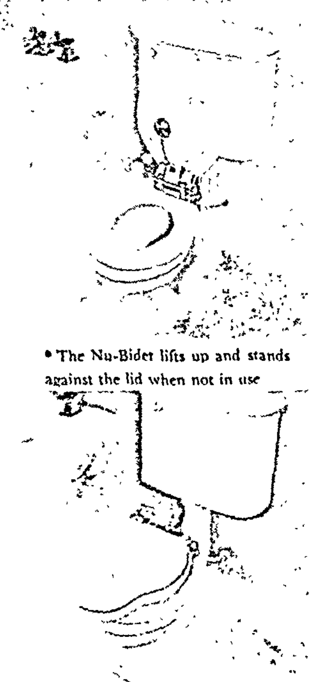
... and Now the **TRULY** Hygienic Bathroom





• The Nu-Bidet lifts up and stands against the lid when not in use

• A complete unit of Toilet Seat, Bidet and Lid. Installed in less than two hours on any standard size bowl.

● And whoever heard of a hygienic bathroom? And *fewever* heard of a bidet, for that matter.

And most all who have, pronounce it "bidet" instead of "*bee*-day."

Once you see the Nu-Bidet (Nu-*Bee*-day) you, too, will agree it is the most outstanding improvement in bathroom fixtures in the past twenty-five years.

That is a factual statement. Here is the proof. The Nu-Bidet is a thoroughly modernized Sitz Bath... *and more. These four uses make it a safe*guard to health and as necessary to personal hygiene as your tooth brush or the bathroom itself.

Sitz Bath for personal hygiene and treatment of rectal disorders. Spray for same purpose and for feminine hygiene.

Attachment for douche, enema and hydrotherapeutics, entirely eliminating the old rubber bag method.

Every doctor who has seen the Nu-Bidet has given it his unqualified approval.

The American public is bathroom conscious and hygiene minded. They are demanding *new* things. The Nu-Bidet is their answer to a long felt need. It is a complete unit of toilet seat, Nu-Bidet and lid in one assembly, which replaces the regular seat and lid. It can be completely installed (including hot and cold water connections) on any standard size toilet bowl in less than two hours. It will convert the ordinary bathroom into one that is *truly* hygienic at a very moderate investment.

Send coupon for beautiful brochure, "Your Answer to a Long Felt Need." *No obligation.*

Entered as second-class matter at the Post Office at Albany, N. Y., September 17, 1932.

BUSINESS or pleasure may take you along strange roads and to strange places. But the lines to home are never broken. Day and night—north, south, east and west—you are in touch by telephone.

The privilege of talking with almost any one, any time, anywhere is distinctly American. Service in this country is not limited to large cities, thickly populated centers or certain hours of the day.

Of the 34,000,000 telephones in the world, more than 50% are in the United States—connected with the Bell telephone in your home or office.

This country also leads in the number of telephones in relation to population, with 13 for every hundred people. The average for Europe is less than three.

Universal service in this country did not just happen. It has been made possible by the development of the Bell System over the past half-century.

Vaccination control of rabies

with CANINE RABIES VACCINE

RABIES VACCINE (*Human*)

Lederle

In the control of Rabies the fundamental problem is the prevention of RABIES IN DOGS.

The annual vaccination of all licensed dogs is a worthwhile procedure. It does not entail undue expense or inconvenience. This annual preventive vaccination of unexposed dogs is accomplished by a single injection of 5 cc. of killed Rabies vaccine. The procedure was developed and proven in Japan by UMENO and DOI, and was introduced into the U. S. A. by *Lederle* in 1921 after experimental tests by EICHHORN and LYON had confirmed its value.

•

In man, Rabies becomes a problem only when a person is bitten by some rabid animal.

RABIES VACCINE *Lederle* for use in man is a 14-dose treatment, using killed Rabies vaccine prepared by the Semple Method. Each dose is alike and is administered in the original volume and strength as advocated by Semple (2 cc. of a 4% brain suspension).

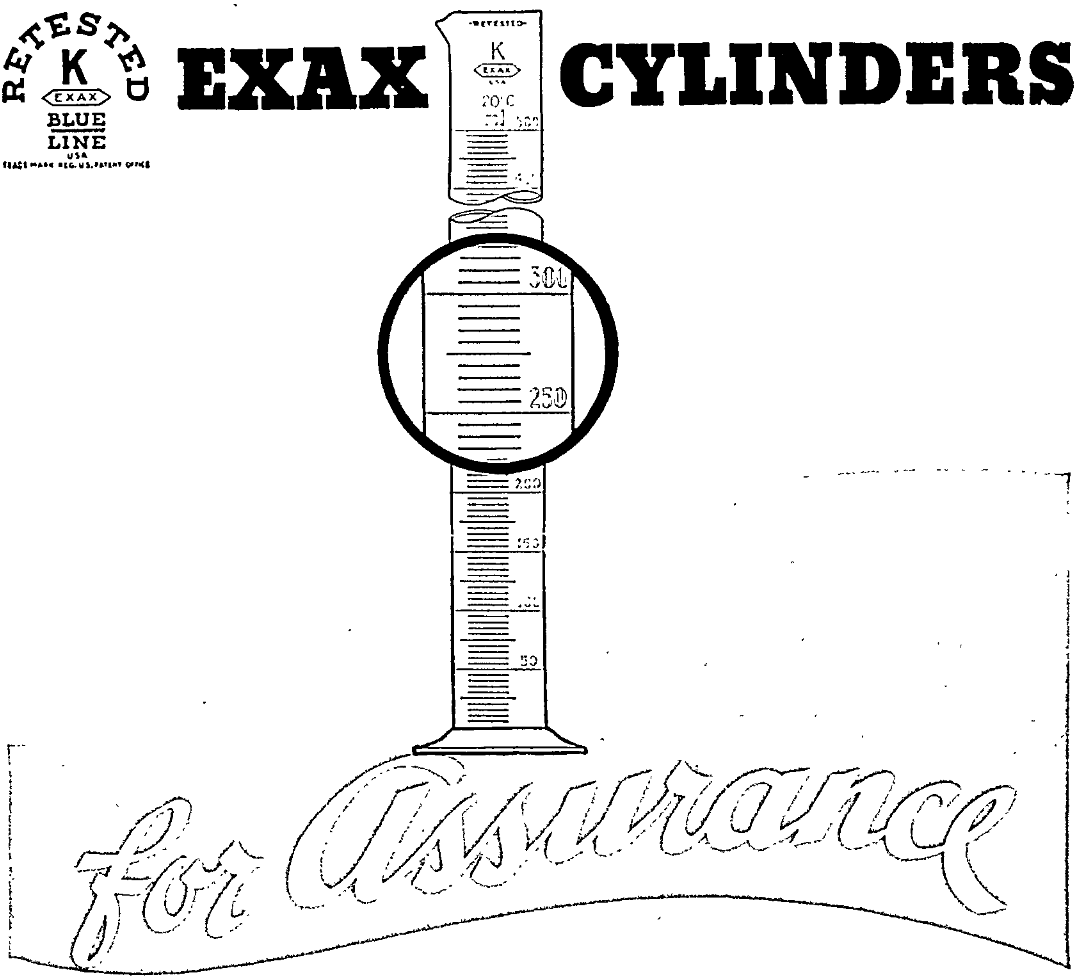
INDEX TO ADVERTISERS

EXAX CYLINDERS



Kimble Blue Line EXAX Cylinders are an accepted standard of accuracy and quality in scientific and industrial fields. Blown in paste moulds to produce a lustrous, highly polished surface, they permit reading of all liquid levels without error or distortion. They are thick-walled and sturdy. Lips are finished so that liquid can be poured slowly without running down the sides. Bases are wide and bottoms are ground to rest perfectly level.

VALUABLE FEATURES

(1)—Calibrated at 20°C at enough points to assure accuracy of ALL divisions.

(2)—Lined and numbered by automatic machines, using an entirely new type of lining for accurate and rapid reading: short lines for intermediate divisions, with full encircling lines at main points.

(3)—All lines are deeply acid-etched and filled with a durable *blue glass*, fused in. The *blue lines* and *new type of calibration lines* assure increased ease of reading.

(4)—Thoroughly retempered (strain-free) to eliminate weak spots.

(5)—Retested for assured accuracy. The following tolerances are allowed:

5 ml	±0.10 ml	250 ml	± 1.4 ml
10 ml	0.10 ml	500 ml	2.6 ml
25 ml	0.30 ml	1000 ml	5.0 ml
50 ml	0 40 ml	2000 ml	10.0 ml
100 ml	0.60 ml		

Stocked by leading Laboratory Supply Houses throughout the United States and Canada.

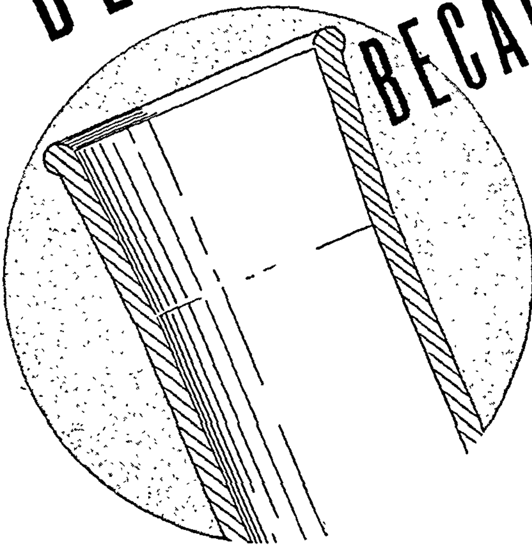
BETTER BECAUSE UNIFORM



PYREX KJELDAHL FLASKS

WITH TAPERED NECKS FOR ACCURATE STOPPER FIT

PYREX Brand Kjeldahl Flasks (Catalogue No. 1760) are now accurately sized to take standard rubber stoppers. (See list below.)

This improved design speeds up Kjeldahl determinations by providing quicker, more precise fitting of stoppers. It prolongs the life of stoppers through easier and more uniform fit. It minimizes the possibility of breaking the flask when inserting the stopper. And, in addition, the neck of the flask has been given increased mechanical strength.

These improved Kjeldahl Flasks may be obtained from your regular dealer at *no increase in price.*

"PYREX" is a registered trade-mark and indicates manufacture by

New DIET AID fills vital need

Class 1, the quart-a-day drinkers are no problem. But Class 2, those who drink insufficient milk, and Class 3, those who drink no milk at all, present a serious dietary situation.

For milk is one of the best food sources for CALCIUM—*and Calcium is probably the greatest single deficiency in the American diet.*

More and more, physicians and health authorities are recognizing the value of Krim-Ko Chocolate Flavored Drink in making up for this deficiency. For Krim-Ko's true chocolate flavor overcomes taste monotony and taste prejudices. It is liked by all. And Krim-Ko contains all the Phosphorus, Calcium and Vitamin G found below the cream line in milk—and is equal to milk in food energy value. Krim-Ko leaves the stomach more quickly and thus does not seriously interfere with the appetite for regular meals.

Krim-Ko is bottled and pasteurized by selected local dairies—and carries the Seal of Acceptance of the Committee on Foods of the American Medical Association.

FREE DIET INFORMATION

Everyone concerned with health and food should have the story of the valuable elements found in Krim-Ko Chocolate Flavored Drink. We shall be glad to furnish you complete information about Krim-Ko and its place in the diet.—Write today to the Krim-Ko Company, 4830 S. Turner Avenue, Chicago, Illinois.

Vitamin D in Child Health*

FRED O. TONNEY, M.D., F.A.P.H.A.
Director, Technical Service and Research, Board of Health, Chicago, Ill.

IT is the purpose of this article to review the more recent experimental data on vitamin D and child health, and point out the essential aspects of the public health problem of rickets. The influence of vitamin D upon the child's physical development is viewed from the standpoint of: (1) growth, (2) bone development, (3) tooth development, (4) posture, and (5) resistance to the infections.

GROWTH AND BONE DEVELOPMENT

The importance of vitamin D to normal growth probably depends upon its property of causing the absorption and utilization of lime salts from the food. Since the lime salts are the principal component of bone, and the size of the skeleton determines height and breadth, it follows of necessity, that vitamin D and lime salts are essential to growth.

There are two requisites for the normal development of bone: (1) ample lime and phosphorus in the diet, and (2) sufficient vitamin D to assure their adequate absorption. The vitamin D may be derived from (a) actinic sunshine, (b) artificial ultra-violet light, and (c) foods, either naturally or artificially fortified with this nutritional factor.

TEETH

With respect to tooth development, vitamin D and lime salts in adequate amounts, are both admittedly essential. As to dental decay, however, recent studies [1] seem to be of importance. These consisted of histological examinations of the teeth of 125 pregnant rats kept on rachitic and non-rachitic diets. The following conclusions were drawn:

A deficient calcium-phosphorus ration in the diet of the mothers, with even a partial deficiency of vitamin D caused improperly calcified teeth in the offspring. In this case, later addition of adequate amounts of vitamin D to the diet failed to correct the deficient calcification of the teeth, but did produce normal bone formation in the experimental animals. Diets with a calcium-phosphorus ration of Ca-1 to P-1.90 did not induce caries in the teeth, whether vitamin D was deficient or not.

On the subject of tooth deficiency and rickets, Eliot, Souther, Anderson,

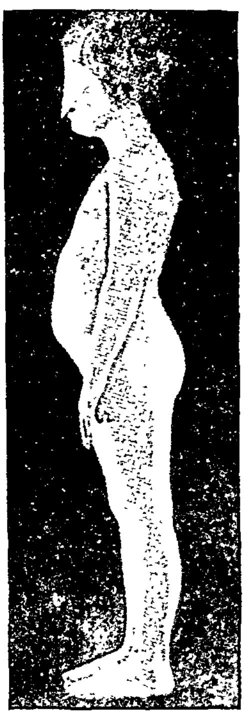
* Read at a Joint Session of the Food and Nutrition and Child Hygiene Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

and Arnin,[2] recently studied the teeth of 450 children in New Haven. Enamel hypoplasia of the permanent teeth formed during infancy and early childhood, characterized by symmetrical distribution of the defects, was observed to be "regularly associated with rickets." Dental caries also, occurred more often in the rachitic children, than in the non-rachitic. Suitable antirachitic therapy was found to reduce the incidence of enamel hypoplasia decidedly, and also, to some extent, the dental caries.

POSTURE

With regard to posture, we quote Park and Eliot: [3]

> In the active and moderate stages of rickets, the muscles are characteristically flabby and lax. In addition, the neuro-motor development of normal growth is impaired, if the rickets is severe. In the milder stages of rickets, however, the neuro-motor development may proceed uninterruptedly.



(*Hygeia*, Mar., 1935, p. 222)

FIGURE I—A rachitic child in typical lax posture

Lax muscles necessarily cause a slump in posture. This is a matter of common observation. Figure I shows a rachitic child in a typically lax posture. Figure II shows a child with good muscle tonus, in a normal posture.

The point is, that a healthy child naturally assumes a correct posture, whereas a rachitic child, because of lax muscle tonus and faulty bone development, often stamps himself as abnormal by his posture alone.

SUSCEPTIBILITY TO INFECTION

Animal experiment — The accumulated material on increased susceptibility to infection in rickets, is now impressive. Of the more recent contributions, one is cited.[4]

A strain of *Bact. coli communis* was used. It was found that a 2 hour daily exposure to mid-day sun for a period of 4 weeks, markedly raised the resistance of young rachitic rats to infec-

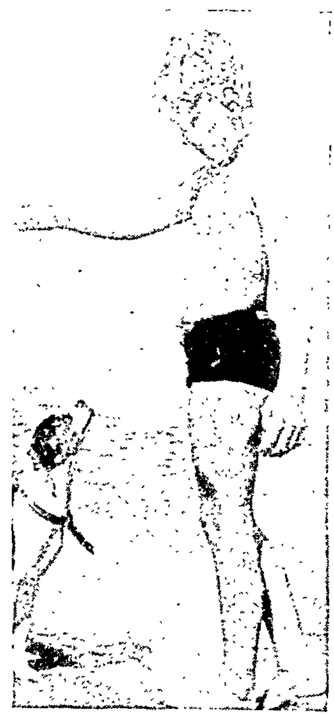


FIGURE II—A normal child with good muscle tonus in naturally assumed posture

tion with this organism. Of 263 sun-exposed rats, 57 per cent survived the inoculation, whereas of 241 controls not exposed, but 32 per cent survived the inoculation. Normal rats, however, were apparently not influenced by exposure to sunlight in their resistance to this infection. The author remarks that "apparently exposure to the sun does not increase the resistance of normal rats."

Brown and Tisdall[5] have reported a series of observations on the effect of a 2 hour daily exposure to sunshine upon rats inoculated with a special "low virulence" organism, previously isolated from albino rats. It was found that twice as many of the sunshine-exposed group survived intraperitoneal inoculation as did the control group, kept indoors away from sunshine.

Eichholz and Kreitmair[6] found that all of the rats fed diets deficient in vitamin D succumbed to an induced pneumococcic infection, whereas 50 per cent of the normal rats inoculated, resisted the infection, and eventually recovered.

Again, Grant, Bower and Stegermann,[7] experimenting with vitamin-deficient diets in pregnant rats, succeeded in infecting the offspring of mothers kept deficient in vitamin D during pregnancy with the tubercle bacillus, whereas normal rats are known to be quite resistant to this infection.

Human suceptibility—It has long been observed by pediatricians, that children with rickets, even of minor degree, are more than ordinarily subject to the common infections of childhood. The late Dr. Alfred S. Hess emphasized this point in a national radio address, under the auspices of the American Public Health Association, on September 27, 1933. He stated in part, "The most common nutritional disorder among infants in temperate zones is rickets . . . its chief danger is, that it lowers resistance to infection."

Mader and Eckhard, of the University Children's Clinic, Frankfort, Germany,[8] reported an investigation on more than 6,000 children, dealing with the relative incidence and fatality rates of 3 common infections of childhood, for the rachitic and non-rachitic groups. Whooping cough had an incidence of 46 per cent in the non-rachitic, and 54 per cent in rachitic children. The pneumonia incidence among the whooping cough cases was 29 per cent in the non-rachitic, and 37 per cent in the rachitic subjects, with equivalent fatality rates of about 46 per cent. In children with rachitic deformity of the chest, however, the pneumonia rate rose to 55 per cent, and the extremely high fatality rate of 81 per cent was recorded.

For measles, Mader and Eckhard report an approximately equivalent initial incidence in both rachitic and non-rachitic children, *viz.*, 50.6 per cent and 49.4 per cent, respectively, but the pneumonia incidence in the rachitic group was 34 per cent as against 24 per cent in the non-rachitic. Again, of those children having rachitic deformity of the chest, the rate of pneumonia was 58 per cent—more than twice as great—and of these, 75 per cent died—whereas the usual fatality from the pneumonia in measles was about 35 per cent.

Again, in diphtheria, Mader and Eckhard's comparison of the rachitic and non-rachitic cases developing bronchial stenosis, seems significant. Of the 454 non-rachitic cases of diphtheria included, but 15 per cent developed stenosis, whereas of 61 cases with rickets, 62 per cent, developed bronchial stenosis. The deaths for non-rachitic cases of diphtheria with stenosis were 35 per cent, and for the rachitic, 62 per cent, approximately twice as many. However, the small number of rachitic cases in this latter series leads us to regard the findings

as probably significant but not conclusive.

RELATIVE INCIDENCE OF RICKETS, COMPARED WITH THE COMMON INFECTIONS OF CHILDHOOD

For many years, there has been a lack of recognition of the extremely high incidence of rickets in the cities, compared with the other common ailments of childhood. Probably the reason for this lies in the different manner of reporting—rickets being commonly stated in percentages, based on specific surveys, and the infections being recorded in rates per 100,000 of population.

To appreciate the relative incidence of rickets and the infections, it is necessary to state them both in the same mathematical unit. Let us choose percentages for our comparison here.

Rickets in some degree, on the basis of recent surveys in American cities, is conceded to be present in at least 50 per cent of the urban child population under 2 years of age. As to the infections, the studies of S. D. Collins [9] on the incidence of the common communicable diseases are to be considered. The data of this study were compiled from personal histories of large groups of individuals at the given age groups, in various localities of the United States.

For the age group 1½ years, within which most of the rickets initially occurs, the following percentage incidences are given by Collins, for four of the common infections:

Measles	11.4%
Scarlet fever	.08%
Whooping cough	10.5%
Diphtheria	.6%

TABLE I

REPORTED CASES OF CERTAIN COMMUNICABLE DISEASES
CHILDREN UNDER TWO YEARS
1927–1934

* Estimated population 50,000 in each year up to 2 years or a total population of 350,000 for the 7 year period

Turning to another source of data on the prevalence of the infections, based on the reported cases in a large urban community, Table I, for Chicago, covering a 7 year period from 1927 to 1934, is of interest.

In Chicago, the average percentage incidences under 2 years, reported to the Board of Health for the four infections, were:

Measles	3.2%
Scarlet fever	1.3%
Whooping cough	2.7%
Diphtheria	.8%

The lower level of reported cases in Chicago, compared with Collins's data obtained by case histories, may be explainable on several grounds, such as unreported cases, a variable incidence in different localities, and the different time periods under investigation.

However, accepting for purposes of comparison the higher incidences reported by Collins, of which the maximum was 11.4 per cent for measles, it becomes obvious that the incidence of rickets is far higher than any of the common infections of childhood—at least in the cities. As such, it surely deserves the attention of the health officer, and especially in its contributory relation to the infections.

THE ANTI-RACHITIC AGENTS

What progress has been made with the several anti-rachitic agents recently advocated for the cure, prevention, and possible eradication of rickets? We must frankly admit that we do not know. One thing, however, is clear—that in sum total, the anti-rachitic agents are yielding definite results. The incidence of rickets is slowly but surely receding. Severe rickets is now seen only occasionally, even in the cities, and mild rickets, as an easily recognizable clinical entity, is also on the decline.

The latest of the generally applicable anti-rachitic agents is vitamin D milk, produced by three processes—irradiation, fortification, with a concentrate, and the feeding of irradiated yeast to cattle. Its potential usefulness toward solving the public health problem of rickets, cannot as yet be judged. However, Table II, based on the easily recognizable symptoms and marks of rickets in the preschool group of children in Chicago, examined routinely year by year in the infant welfare stations from 1926 to 1935, inclusive, shows a decided decrease in rickets. These figures cannot be regarded as representing the total incidence of rickets in the community, because of the cursory nature of the examinations and because the data include healed rickets, which does not in any sense indicate the initial incidence, since the

milder forms heal without leaving any evidence.

The total amount of easily recognizable rickets found within the last year, in this preschool group of children, declined from 13.7 per cent in 1933 to 7.1 per cent in 1935. Mild rickets also dropped from 10.4 per cent in 1933 to 5.3 per cent in 1935, and moderate rickets from 3.5 per cent to 1.8 per cent. Severe clinical rickets apparently began to yield to earlier preventive measures, as far back as 1932, with an incidence of 0.2 per cent in the preschool children routinely examined. It is interesting to note that the item of severe rickets reached 0.03 in 1935.

Within the last year, the only anti-rachitic influence calculated to affect the child population generally in Chicago, is vitamin D milk (Table III), the sale of which was authorized by ordinance on April 24, 1934, and began immediately thereafter. The general sale of vitamin D evaporated milk in Chicago began at about the same time. Since then, the percentage of vitamin D fluid milk consumed in the city, as indicated by quarterly surveys, has remained constant at about 6 per cent of the total sales. In addition, there was consumed, according to the best estimates obtainable, about one-fourth to one-third as much evaporated milk, of which approximately 50 per cent was vitamin D milk. No other unusual factors likely to affect the prevalence of rickets were operative within the year, so far as we know.

SUMMARY

There has been tardy recognition of the relative public health importance of rickets among the common ailments of childhood.

Recent experimental evidence shows quite definitely that the public health importance of rickets lies principally in its contributory relation to the infections of childhood, such as measles, scarlet fever, whooping cough, and diphtheria.

Definite conclusions regarding the efficacy of the latest addition to the generally available anti-rachitic agents, vitamin D milk, are not yet possible. The time since its introduction is too short, and unfortunately the volume of fresh vitamin D milk consumed is still far too small to permit of satisfactory evaluation.

However, the combined consumption of fresh and evaporated vitamin D milk in Chicago, during the past year, amounting to about 25 per cent of the total sales of milk, when considered in

connection with the recently noted decrease in clinically-recognizable rickets among the preschool children, is sufficiently suggestive to justify more general trial of this fortified food product, as an anti-ricket reagent.

When the total sales of both fluid and evaporated vitamin D milk reach about 50 per cent of the total sales of each, the real test of the product as a general anti-rachitic agent, will have begun.

Charles Kingsley on the Laws of Health

IT was in 1879 that Charles Kingsley had recognised that the best knowledge of the time concerned the new light on the laws of health. "I am going," he writes, "to throw myself into this movement. I am tired of most things in the world; of sanitary reform I shall never grow tired. No one can accuse a man of being sentimental over it, or of doing too much of it. There can be no mistake about the saving of lives, and the training up of a healthy generation." Again he says, "I see more and more that we shall work no deliverance till we teach people a little more physical knowledge. I have refused this winter to lecture on anything but the laws of health." Since Kingsley's days there have been many changes, but not one which has impaired the truth of his writings. Let us, therefore, aim at increased efforts toward securing an enlightenment of the people in regard to the health of the community, for in this way we find the true source of health and happiness. —James Fenton, M.D. Public Lecture to the South African Health Congress, *J. Roy. San. Inst.*, May, 1936, pp. 646–647.

Effect of Relief Programs on Public Health Nursing in the State*

Preparation of Nurses

EVA F. MACDOUGALL, R.N., F.A.P.H.A.
Director of Public Health Nursing, State Division of Public Health, Indianapolis, Ind.

THERE has been a Bureau of Public Health Nursing in the Indiana State Health Department ever since 1921, but we in the bureau have never had authority over any of the public health nurses employed locally as such bureaus have in states which subsidize nurses' salaries. Our first aim was to raise the standard of preparation of nurses who wished to do community health work, so we kept advising them to get prepared, showing them how and where they could get this preparation, and we kept advising organizations, both official and unofficial, to employ nurses who met the minimum qualifications outlined by the National Organization for Public Health Nursing.

These organizations or officials chose the nurses they pleased if they did not care to take our advice. Nurses thus employed used our daily and monthly report forms and sent us monthly reports—if they liked. We never could get uniformity. We had just reached the point where perhaps half the health officers, school men, and lay boards were beginning to realize that the right nurses with the proper preparation in public health could run rings around nurses employed solely because they were home town girls, or personal friends, or belonged to the right political party. We always dreamed though of what we could accomplish if we only had a little authority so that nurses would have to accept our leadership.

Then the Civil Works (later the Emergency Relief) Administration Program opened up the opportunity, indeed, the necessity, for us to educate and guide a large group of nurses on public health assignments. We quailed at the thought of putting totally unprepared nurses to work in the rural areas and small towns without local qualified public health nursing supervision, but here, partially at least, was a chance to fulfil our dreams, for these nurses were totally dependent on us for salaries, education, and supervision, for 18 months. We did not have time to philosophize over the effect these nurses would have on our standards of public health nursing in the state; we had to get busy.

You who read the *American Journal of Nursing* [1] and *Public Health Nursing* [2] are familiar with the details of our educational program for Indiana ERA nurses. I shall confine myself in

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

this paper to the significant lessons this experience taught us in guiding our future state-wide educational program for public health nurses.

A little professional house-cleaning and refurbishing had to be done before we could begin to prepare the ERA nurses for their community work. For years we had been working with lay boards, especially those of the unofficial health agencies, with groups of teachers, with the social agencies, and with the health officers, to teach them good standards of public health nursing; but we had almost ignored physicians, both individually and collectively. Now, partly as the result of the depression and the *Report of the Committee on the Costs of Medical Care,* we had been hearing vague rumblings from some of the physicians against public health nurses. These new nurses, we decided, must be taught at the start the unwritten laws of public health nursing ethics as they related to the medical profession. Likewise, we had to have the approval and coöperation of the physicians. This double task loomed biggest of all ahead.

The progressive superintendent of schools in one of our most populous counties sent in the first call for nurses—he wanted 6 to do township school nursing in areas that had never had the services of community nurses before. It was here that the rumblings against public health nurses among the medical men had been loudest. The assistant director of our bureau was sent to this county with the tacit understanding that she was not to come back until standing orders for the 6 nurses had been obtained from the local medical society. She did her work well. She convinced the reluctant superintendent of schools that his nurses needed these orders; then she assisted the medical society in formulating them. When completed, they included general directions for children found ill in schools, contained a list of conditions usually requiring exclusion of children from school, outlined what nurses should look for in inspecting school children, listed articles to be carried in the nurse's bag, outlined a simple program for the nurses to carry out, explained first aid procedures the nurse could use and the nursing care she could give in emergencies.

A copy of these regulations [3] found its way to the State Medical Association, where it created a great deal of interest and met with approval. There, mimeographed copies were made and sent to the secretary of every county medical society as a suggestion in case emergency nurses were put on to work in his community. Many copies were furnished our bureau and no new nurse was put on who did not have a copy to be altered or approved by her local medical society.

I have enlarged on the development of these regulations and standing orders because, as we look back, we realize that they were the first measures we designed to educate these new nurses. If the nurses lived up to the regulations we would not need to worry about their professional ethics. We found, too, that endorsement of the regulations by the State Medical Association oiled the wheels for our whole future program, for through them physicians all over the state, especially those who had never worked with public health nurses before, began to realize that community nurses were not trying to supplant them. To show their changed attitude, last winter the legislative committee of the State Medical Association put a clause in the full-time health officer bill giving public health nurses in Indiana a legal status for the first time in history.

Advisory nurses working by districts in the field were the next major measure we launched to educate the nurses. No program would have lasted without

them. All of them had too many counties and new nurses, but they did heroic work. They not only had to assist new ERA nurses in getting started, but no service was begun in a new community until they had made a visit there, seen the prospective nurses, helped to select the official sponsor, and made their recommendations to our bureau.

The 37 one-day institutes our bureau conducted in different sections of the state were an important factor in making for the efficiency of our new community nurses, and they had far-reaching effects in stimulating general nursing education in the state. However, it was the district advisory nurses—who attended each institute and assisted in conducting the program, and then taught the nurses in the field how to apply what they had learned at institutes to fit their individual situations—who made the education really carry over. We must never forget this fact.

ERA nurses on well organized public health nursing staffs were required to attend the institutes, even though they had the benefit of local staff education facilities. They and their supervisors contributed a great deal to the technical discussions and demonstrations. Most of them were doing bedside nursing. They learned a great deal too, because they got an insight into the complicated problems of county nurses who worked in rural or isolated areas, and who often had no hospital or social agencies in their territories to help them.

We learned that our bulletin *Echoes*, which has always been enjoyed by our regular public health nurses, was a potent factor in educating and stimulating ERA nurses and giving them a group feeling and pride. In it we put proposed plans, new rules and policies, announcements of institutes and meetings, news notes, extracts from narrative reports, and other educational matter. ERA nurses all read *Echoes* and solemnly took to heart all the suggestions it gave.

We learned that nurses can be stimulated to make narrative as well as statistical reports, which give a real picture of situations and problems and how they are met that is invaluable to a central bureau striving to help them. Edna L. Foley, R.N., of the Chicago Visiting Nurses' Association wrote us commenting on the case stories from ERA nurses which she read in *Echoes:* "I always feel that a narrative report is so much more interesting than a statistical one, but it is 50 times harder to wring from the nurses." We agree, but we found it could be done.

We could see a gradual improvement in the effectiveness of the ERA nurses' services as time went on. Their questions and responses in institute discussions, the advisory nurses' reports of their services, the nurses' own case stories given in their monthly narrative reports, showed that they were learning how to teach and organize; and many of them showed an uncanny understanding and practice of the art of public health nursing.

The whole demonstration changed our views somewhat about the preparation of new nurses for their jobs. We had thought that it would be calamity if a nurse took a public health position without a theoretical course or well guided experience, or both. Now we know she can do fairly acceptable work if trained right on the job, provided she is responsible to a central bureau well enough trained and staffed to give her education and supervision. We had thought too that nurses did better when working in communities away from their homes. Working at home did not seem to handicap Indiana ERA nurses.

I said early in this paper that we always dreamed of what our bureau could accomplish if we had a little

authority behind our leadership of public health nursing in the state, but we never dreamed that the results of such an opportunity would have such far-reaching effects, for a by-product of our institutes for ERA nurses was the creation of a desire among all nurses to know more about public health. They lead to state university extension classes in Principles of Public Health Nursing and Social Work for Nurses, which approximately 75 ERA nurses took last winter in several centers in the state; 65 institutional nurses also attended, and around 90 regularly employed public health nurses. Other well attended extension courses for nurses are being given in 7 centers of the state this year. Credits received apply toward the B.S. degree with a major in public health nursing. Many of the ERA nurses who are being employed to continue their programs with local official and unofficial funds took university summer courses approved by the N.O.P.H.N., and are continuing with their extension classes this winter. They are not through. They have had a taste of education in public health; they see their needs and opportunities.

The institutes and extension classes and general ERA nursing program led to the adoption by the State Board of Education in June of higher regulations for school nurses which were formulated by a special committee of the State Nurses' Association to advise the director of the Licensing Bureau, State Department of Public Instruction. The State Bureau of Public Health Nursing collects the professional histories of all nurses applying for school nurses' licenses and assists the Licensing Division in deciding what nurses are eligible for permits or licenses. To the Bureau of Public Health Nursing also falls the placement and supervision in the field of all school nurses.

The whole ERA nursing program led too to the better regulations and higher requirements for public health nurses employed by county commissioners and city councils which were formulated by the State Board of Health in July and made the responsibility of our bureau to administer and enforce.

In the past the standard of training of public health nurses employed by the unofficial health agencies has been somewhat higher than that of the nurses employed by the official health agencies. Now, however, with the new regulations, all officially employed public health nurses will have much higher standards.

I said that the main thing we learned from our ERA educational program was that in an emergency nurses in a state-wide program in public health can be trained pretty well on the job if a central agency like the Bureau of Public Health Nursing of the State Health Department has the trained personnel and the authority to do it through institutes and adequate supervision, supplemented by extension classes and summer courses. However, we still feel that regularly employed public health nurses should have the N.O.P.H.N. Minimum Qualifications [4] before taking their positions, and our new regulations for officially employed public health nurses require this. Initial preparation for public health nurses, though, is not enough. They must be constantly learning. We feel that one of the greatest tasks of our bureau in the future should be the arrangement of a continuous educational program for refreshing and stimulating public health nurses already employed, especially those without local supervision. Now that our bureau has more authority over the officially employed nurses we can plan such a program.

A recent survey made among rural and small town nurses in New York, Minnesota, Ontario, and Indiana by

a public health nursing student in Teachers College, Columbia University, showed they would welcome more supervision of the right kind, and felt the need of more assistance than they had been getting in organization work, program planning, community relationships, family case work, publicity, and records.

The Sanitary Code

IN 1842 a report was published on the sanitary conditions of the labouring population of Great Britain. It was an elaborate description of the shockingly insanitary conditions under which the masses of the people were living in every part of the kingdom. The report pointed out that the formation of habits of cleanliness was obstructed by defective water supplies; that the actual loss of life from diseases induced by dirt and bad ventilation was greater than in any wars which the country had been engaged upon in recent times; and that the effect of the conditions upon the population was to make them short-lived, improvident, reckless and intemperate.

The first medical officer of health in England was appointed in 1847 for the City of Liverpool. London followed a few months later. The first Public Health Act was adopted in 1848 at a time when an epidemic of cholera was ravaging the country. In 1860 we were in the midst of a severe epidemic of typhus fever, and cholera again appeared. Further Acts of Parliament were introduced to deal with urgent problems, and public health legislation multiplied until in 1875 all the sanitary laws were consolidated in the great Public Health Act of 1875, which is the greatest sanitary code ever enacted in England or any other country. That Act has been the basis of public health legislation introduced in many quarters of the world; it has stood the test of time and is still on the statute book.—James Fenton, M.D., Public Lecture to the South African Health Congress, *J. Roy. San. Inst.*, May, 1936, p. 641.

Diagnosis of Infectious Mononucleosis in Public Health Laboratories*

C. A. STUART, PH.D., AND FRIEND LEE MICKLE, D.SC., F.A.P.H.A.

Professor of Bacteriology, Department of Biology, Brown University, Providence, R. I.; and Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.

IN 1885 Filatow[1] presented a somewhat meager description of a glandular disorder of humans which he considered to be a disease entity. Four years later an accurate detailed description of similar cases was made by Pfeiffer[2] who recognized the condition as an infectious process characterized by very definite symptoms to which he gave the name "glandular fever." Before the close of the century this disease had been reported from all important medical centers throughout the world, the first case histories in this country having been published by West in 1896.

Because of its benign nature, perhaps, little attention was devoted to glandular fever until about 1918–1920 when several persons who had what was diagnosed as hopeless acute lymphatic leukemia recovered wholly in from 1 to 2 weeks. This so stimulated interest in glandular conditions in general that within a few years considerable literature on the subject had accumulated. Unfortunately, because of variations in symptoms and lack of historical knowledge, several names have been assigned to the same or similar conditions. Of these, 3 are in common usage at the present time: glandular fever, monocytic angina, and infectious mononucleosis. The last term appeared first in a report by Sprunt and Evans[3] in 1920, and has been more generally accepted in this country than abroad where "glandular fever" is more commonly used. Attempts have been made to apply these terms to what some contend are quite different infectious processes, namely: glandular fever, characterized by marked glandular enlargement usually in children from 5 to 15 years old; monocytic angina occurring in the 10–25 age group, characterized by a membrane in the throat clinically indistinguishable in appearance from diphtheria; and infectious mononucleosis, the febrile type occurring in adults, characterized by temperatures of 102° to 104° and maculo-papular eruptions frequently indistinguishable from those of typhoid fever, or rubelliform eruptions indistinguishable from rubella. No strict line of demarcation, however, exists between these conditions since occasionally all symptoms may occur in a single individual, and it is generally conceded that the different syndromes are but different manifestations of one and the same disease. From the standpoint of priority then, glandular fever is the proper appellation for this condition but "infectious mononucleosis"

---

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

appears to us to be a more descriptive term.

The epidemic nature of infectious mononucleosis with an incubation period of from 5 to 15 days seems clearly established by the extensive reports of Tidy[4] and many others. Sporadic cases for the most part are more severe than the epidemic form, but in other respects the two forms are not significantly different. The degree of infectivity is not great though on occasions all members of a group may contract the disease, particularly when the group exposed is composed of children. Contact infection seems to occur only in the early stages of the disease and direct contact or throat droplet infection is probably the mode of transmission. Isolation of cases until 1 week after the temperature has returned to normal has been recommended.

The incidence varies considerably. Widely distributed epidemics, notably the 1930 epidemic in England, and large numbers of sporadic cases have been reported abroad. The number and extent of epidemics and the number of sporadic cases * in the United States are not great but it is believed that as more and more attention is given to this disease by public health authorities more cases will be found with a possible decrease in the incidence of those diseases for which infectious mononucleosis is commonly mistaken.

Infectious mononucleosis is usually encountered in the benign form though on occasion complete prostration with marked dehydration has been noted. Fatal cases are rarely reported unless there have been complications. Recurrence of the infection after several weeks is not uncommon, and recurrence after months and even years has been known. This may be taken as evidence that a single attack of the disease does not confer immunity. It should be pointed out that marked debility may be noted in some cases for from 6 months to a year following the onset of the disease.

The causative factor in infectious mononucleosis is still an open question. *Listerella monocytogenes* isolated from rabbits by Murray[5] and *Bacterium monocytogenes* isolated from an apparent case of the disease in man by Nyfeld[6] both lack confirmation as the etiological factor. A protozoön, noted by Bland[7, 8] who was able to produce a rapid and fatal febrile condition in rabbits and monkeys by the injection of blood from positive human cases of the disease, appears to be a normal inhabitant of many animals. Other organisms which at one time or another have been proposed as the infective agent all lack confirmation.

Whatever the cause or the course of the disease it is obvious that the clinician is dealing with an infectious and contagious disease, the importance of which lies not so much in the severity of the infection as in the confusing nature of the clinical symptoms. As previously pointed out, infectious mononucleosis in certain stages of the disease may be readily confused with typhoid fever, diphtheria, rubella, lymphatic leukemia, and less important conditions. An accurate laboratory diagnosis not only permits prompt reassurance of the patient by the physician but may save the public health officer considerable time and energy.

The blood picture in infectious mononucleosis, which is characterized by a more or less marked decrease in the polynucleated cells, with an accompanying absolute increase in the mononucleated cells, many of which are decidedly abnormal forms, offers a more satisfactory method of diagnosis than

* Working with a small group of physicians in Providence and Hartford since 1933 we have encountered to date 62 clinically, cytologically and serologically positive cases of infectious mononucleosis.

any one symptom. Even here, however, in some cases a marked "shift to the left" in the polynucleated cells with the appearance of the more primitive forms may be suggestive of myelogenous leukemia. On the other hand, since the absolute lymphocyte count often reaches a high level with the appearance of immature forms, particularly bi-nucleated cells, the picture may on occasion be almost indistinguishable from lymphatic leukemia. In view of the variations in both the clinical and cytological pictures a specific serological test would be of great value in diagnosis.

Paul and Bunnell,[9] in 1932, proposed a serological diagnostic test based on the presence of sheep heterophile antibodies in the blood of the patient. The heterophile antibody concerned may be defined as an antibody reacting with an agent other than and phylogenetically unrelated to the specific antigen responsible for the production of the antibody in question. The presence of increased sheep heterophile antibodies in the blood in cases of infectious mononucleosis was rapidly confirmed by a number of independent investigators. Furthermore, it was demonstrated that such antibodies were not increased in those diseases to which infectious mononucleosis so often bears a close resemblance.

The test originally devised by Paul and Bunnell and slightly modified by Stuart, *et al.*[10] consists of adding 0.5 ml. of 1 per cent suspension of washed sheep cells to 0.5 ml. of serial dilutions of the patient's serum. The tubes are incubated at 37° C. for 2 to 4 hours and the degree of agglutination noted. In the routine diagnosis of infectious mononucleosis it is not advisable to incubate the tests over night in the icebox since, as pointed out by Stuart, Tallman, and Brintzenhoff,[11] many normal sera with little or no sheep cell titer at 37° C. may show a titer as high as 1:160 when tested at 5° C. With confirmatory clinical and cytological evidence, a titer ranging from 1–80 to 1–10,000 at 37° C. is with few exceptions a positive diagnosis of this disease.

The test as described is wholly satisfactory as a diagnostic or confirmatory diagnostic test in a large majority of infectious mononucleosis cases, yet conditions do exist under which a serum of moderately high or even very high titer may be erroneously reported positive. Sheep heterophile antibodies similar in character to those found in infectious mononucleosis had been previously demonstrated by Davidsohn[12] and many others in the blood of individuals after injections of native or therapeutic horse serum, particularly when serum sickness developed. Moreover, it was shown by Davidsohn,[13] that such antibodies might persist in the blood of a patient for a year or more after treatment with horse serum. Should the serum from such an individual be submitted for an infectious mononucleosis test at any time previous to the disappearance of the sheep heterophile antibodies associated with the serum sickness, the routine procedure described would be valueless.

In an attempt to differentiate between the sheep agglutinating antibodies resulting from these two pathological conditions, Stuart, Welch, Cunningham, and Burgess[14] found that the sheep antibodies in serum sickness were completely adsorbed by emulsions of guinea pig kidney whereas those of infectious mononucleosis were not. In certain cases of serum sickness a gland condition resembling infectious mononucleosis is observed, but the blood picture does not resemble that of infectious mononucleosis. Should an apparent infectious mononucleosis case with a history of serum treatment give a high sheep cell titer, 1 ml. of a 1:5 dilution of the serum is adsorbed with 0.25 ml. of a

finely ground and washed emulsion of guinea pig kidney (Stuart[15]) for 1 hour at 37° C. with frequent stirrings. The mixture is then centrifuged and the supernatant fluid tested in serial dilutions for the presence of sheep cell agglutinins. If the sheep agglutinins are completely or almost completely removed by adsorption with guinea pig kidney, heterophile antibodies of the infectious mononucleosis type are not present. On the other hand, if the original sheep cell titer of the serum is not significantly reduced by the adsorption, the heterophile agglutinins of infectious mononucleosis are present.

Normal human serum possesses sheep heterophile agglutinins and, since the height to which the normal titer may rise has not been satisfactorily determined, it is sometimes difficult to tell whether one is dealing with a high titering normal serum or a low titering mild case of infectious mononucleosis, or a low titer from the early stages of an acute case of the disease. An accurate diagnosis is possible even under such conditions. Bailey and Raffell,[16] and working independently, Stuart, Fulton, Ash, and Gregory[17] noted that the heterophile antibodies of infectious mononucleosis were adsorbed by beef cells, and the latter investigators found that the sheep heterophile antibodies of normal sera were not removed by beef cells. One ml. of a 1:5 dilution of such a questionable serum is adsorbed with 0.25 ml. of washed packed beef cells as previously described for guinea pig kidney. The complete removal or the adsorption of a significant part of the sheep cell agglutinins is indicative of infectious mononucleosis.

The routine test for sheep agglutinins, confirmed if necessary by adsorption with guinea pig kidney or beef cells, will give an accurate confirmatory diagnostic test for infectious mononucleosis. It should be emphasized that the simple routine test is quite adequate for the great majority of cases and its simplicity will make it possible for practically all public health laboratories and most hospitals to carry it out routinely with their present equipment. The special adsorption tests are necessary on occasions and have been employed to excellent advantage in the laboratories of the Charles V. Chapin Hospital and the Rhode Island Hospital in Providence, and in the Bureau of Laboratories of the Connecticut State Department of Health in Hartford. We feel that the laboratory diagnosis of infectious mononucleosis will become increasingly important as a public health procedure as more cases are recognized through the use of a simple but accurate serological test.

Tabulating Machinery for Indexing and General Tabulation in the Vital Statistics Office*

G. W. BAEHNE
International Business Machines Corporation, New York, N. Y.,

AND

HENRY L. PORSCHE
Deputy Registrar, Board of Health, Chicago, Ill.

TO most registrars in public health departments the adequate indexing of birth and death certificates is an irksome and prosaic task, falling into the category of "necessary evils." But it cannot be emphasized too often that records speedily recorded, accurately kept, and quickly available, are the very foundation of an efficiently conducted health department. As the city, state, and federal governments increase their demand for vital statistics as necessitated, for example, by the social security legislation passed by the last Congress, records become more and more important. Therefore, accurately kept, speedily recorded, and quickly available records, are the matters we propose to discuss.

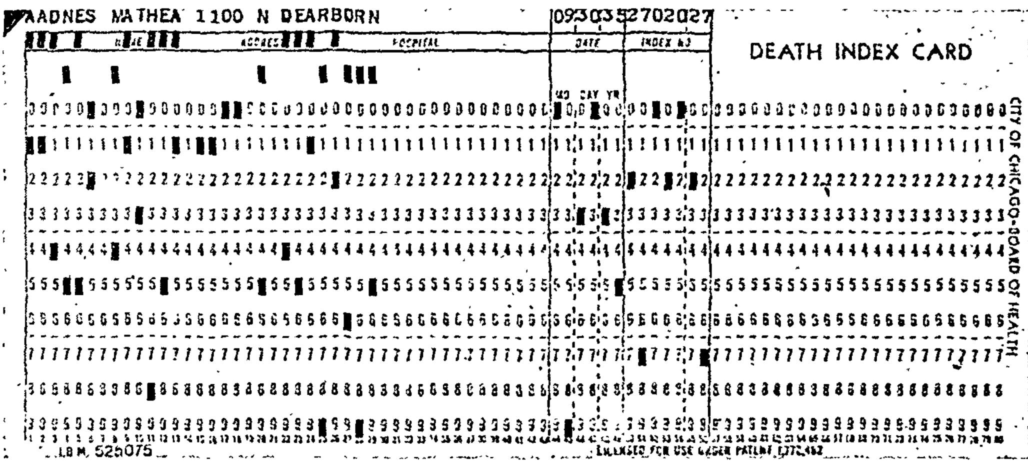
To provide a proper background for an appreciation of the new method of recording to be outlined in this paper, the usual handling of certificates, which has not changed materially for several decades, is worthy of summarization. While the details of the old procedure vary from place to place, the major steps are ordinarily somewhat as follows:

1. The incoming certificates are checked for accuracy and the certificates numbered.
2. Items on the certificates which are to be used as the basis for statistical tables are coded and, in most cases, tabulating cards are punched from this coded information.
3. Concurrently with many of these operations, there are usually prepared statistical tables of various types such as, in a city health department, a list of deaths or a daily analysis of general as well as infant mortality.
4. In most cases, index cards giving, in addition to the above information, some other identifying data such as residence, mother's maiden name, etc., are prepared.
5. Cities or states that maintain printed indices must, at the end of the year, make a copy of all the names in their files either by typewriting them or by spreading out the index cards and photographing them.
6. This copy is then given to the printer who, in turn, must set the information in type, proof-read it, and then return it to the health department to be checked as to its accuracy.

Due to the difficult composition, printing of matter of this sort is a lengthy task, as well as a costly one. Of course, while the index is being set in type—usually consuming a month or more—the index cards are not

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

FIGURE I—Index Card Made With Alphabetic Printing Punch



readily available for use in the office.

Where the old card system of indexing is used, card files soon become very voluminous, to the detriment of the working arrangement of the whole department. The element of human error is greater as the number of index cards in the file increases and, in the larger offices, a vast amount of valuable floor space must be set aside for filing cabinets.

The purpose of this paper is to describe a method which seems to overcome the shortcomings of the hand method and which can be installed without any appreciable amount of capital expense—a very vital factor in these days of meager appropriations and reduced budgets, coupled with the increased demands made upon the registrar's time and facilities.

It seems hardly necessary to elaborate on the punched card method as such. Tabulating machines employing the punched card principle have been used in health departments for almost 50 years, and most persons who received their training in public health work have some degree of familiarity with their operation.

The use of the alphabetic printing machines plays a prominent part in the subsequent description of the new indexing method. Based upon this new development in punched card equipment, the following procedure has been evolved which, with the necessary variations, can be applied to every indexing task:

1. Incoming certificates are checked for accuracy as heretofore. Inaccurate or incomplete certificates are, of course, held for correction or further information.

2. The correct certificates then go directly to the clerks who code and verify them in the usual manner.

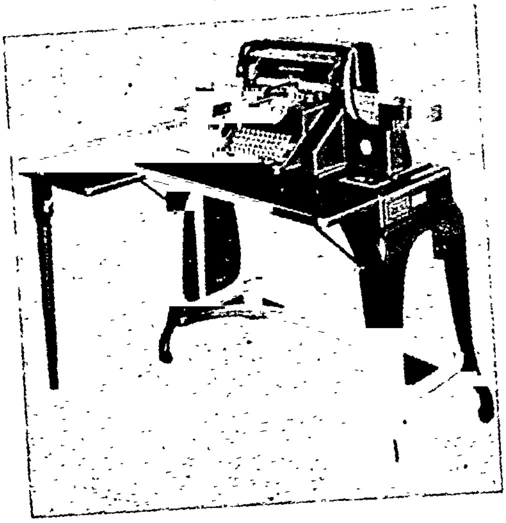
3. Next, tabulating cards are punched for statistical purposes. An index card is now made on a machine which punches and simultaneously typewrites across the top of the card the same information shown in the punched card (see Figure I). This double process of punching and typing is made possible by the development of a new type of machine, called the duplicating printing punch, which combines the punching mechanisms with a standard typewriter keyboard and type (Figure II).

4. The accuracy of the punching is verified by the use of the key punch verifying machine. The cards are then filed by hand, daily, in an alphabetical file.

5. At the end of the year the cards are removed from the file and sorted into strict alphabetic sequence by the electric sorter at the rate of 12,000 cards per hour, thus assuring a strictly accurate list down to the last letter of the name.

6. The cards are then run through the alphabetical printing machine which, at the speed of 80 cards per minute, prints the en-

FIGURE II—Alphabetic Printing Punch



tire information contained on the card—that is, the name, address, date of birth or death, and certificate number—across the width of the paper with one imprint of the machine (Figure III). This printing machine has 88 type bars, 45 of which are capable of printing numeric information only, while 43 can print both numeric and alphabetical information. The type bars in this latter section have 36 characters, 26 for the letters of the alphabet and 10 for the numbers from 0 to 9. This arrangement assures great flexibility and absolute accuracy in the reproduction of names and addresses.

By operating the machine for 10 hours a day, it is obvious that a file involving several hundred thousand names can be completely listed in a very short time. By utilizing paper of the proper size, it is possible to prepare the book indices directly from these sheets by the photo-offset or planograph process. However, if desired, planographing can be dispensed with, as the tabulating machine can produce, by means of inter-leaved one-time carbons, as many as 7 or 8 copies with perfect legibility. Still another possibility is the use of a mimeographed stencil in lieu of paper in the printing mechanism of the tabulating machine. From this stencil, as many additional copies as are needed can be prepared inexpensively. Again, the use of a hectograph ribbon in the tabulating machine enables additional copies to be made on any gelatin duplicators.

By keeping the cards for a number of years it is, of course, entirely feasible to make a cumulative alphabetical index covering 2, 5, or even 10 years, thus enormously reducing the amount of file space and searching time required.

The flexibility of the punched card method makes it practical to have the entire indexing for the state carried on at one central location. Local registrars who would normally file and index their own certificates can now send such certificates direct to state headquarters and within 2 days receive punched and printed tabulating cards already sorted, which they can insert into their own files. At the end of the year, state headquarters, from a duplicate set in its possession, can give the city a printed index, upon receipt of which the detail cards may be destroyed. In states with many medium sized cities, which now maintain separate indexing files, the saving in time and money should be very great.

So far, our discussion has dealt with the use of modern alphabetical tabulating equipment in indexing. However, the same machines that do the indexing job so efficiently can also be of tremendous help in the preparation of statistical tables of all kinds. Tables showing a distribution of causes of death by age groups, sex, and color can easily be prepared. On the basis of punched card equipment now available in many public health departments, such a report requires anywhere from 7 or 8, to 20 separate runs through the card counting sorting machine. In every instance, the figures on the dials have to be read off and transcribed to a summary sheet. The transcription process is fraught with possibilities of error. The summary sheet, in turn,

must be given to the printer for typesetting and the proof must then be checked against the original—two more possibilities for error. The cost of typesetting statistical tables of this kind is high because linotype machines are not practical in this work. Finally, the time consumed is so great that in many instances there is a lapse of several years between the close of the period covered by the report and its actual publication.

Due to the fact that alphabetic listing machines, such as are used in the work previously described, can be furnished with 80 adding counters and with devices which permit the grouping of the data in almost any desired arrangement, running the punch cards through the machine will produce the printed forms in shape for immediate reproduction by photo-offset printing or planographing. As one of the sets of cards is usually maintained in "cause of death" order, no sorting will be necessary at all in such a case, and printed reports could be available in a matter of weeks rather than months or years. Again, by utilizing a mimeograph stencil in lieu of paper in the tabulating machine and by drawing in the dividing lines by means of a stylus, thousands of copies of a table may be made rapidly and very inexpensively.

As to the cost, it may be interesting to know that on the basis of studies made in several cities, notably New York and Chicago, the statement can be made with a reasonable degree of accuracy that photo-offset reproduction or planographing directly from reports prepared by the tabulating machines costs just about one-quarter as much as having the same reports set up in type and printed. This saving does not take into consideration the time required for having the health department check the printer's proof.

To sum up: we have attempted to show in this paper that, by the use of modern alphabetical tabulating equipment, the cost of indexing may be greatly reduced, and accuracy and efficiency of the office increased. We

believe that the machines that make this possible need not be confined to indexing, but that they may be applied with equally salutary results to the preparation of all manner of statistical tables and tabulations.

It should be noted that the size of the health department is not necessarily a factor in determining the applicability of the punched card method. Of late, tabulating service bureaus have been established in principal cities throughout the world, so that a department would need only a punch and a sorting machine of its own, delegating the task of preparing the printed index itself to such service bureaus. In this way, the fixed expense can be held down to a minimum without sacrificing any of the benefits of this method.

Twins

ONE out of every 100 women about to have a baby in New York City, will surprise her husband by presenting him with twins. One out of every 20,000 expectant fathers will be overcome by having to care for three new arrivals. Neither the expectant mother nor father, however, need have much fear of having to provide for quadruplets, for in the recent history of the Department of Health there have been only two sets of quads. These were born in the Bronx in 1934 and all died.

These facts were disclosed May 30 by a survey just completed by the Bureau of Records of the Health Department, New York, N. Y., covering the 14 year period, 1922 to 1935, inclusive. One of the tables is shown here.

Period	*Births, Yearly Average*	*Twin-sets, Yearly Average*
1922–1926	128,717	972
1927–1931	123,611	1,092
1932–1935	103,818	871

From this it may be seen that while births have shown an average yearly decrease of approximately 25,000 between the 1922–1926 and the 1932–1935 periods, the decrease in twins has only been an average of 101 sets a year. Twins, however, have been following the downward trend of births year by year, and this is particularly noticeable from 1928 to the close of last year. In 1928 there were 1,212 sets of twins born, while in the 3 following years, 1929, 1930, and 1931, the average was only slightly over 1,000 sets a year. Since then the 1,000 mark has not again been reached.—New York Dept. of Health Release, May 31, 1936.

Effect of the ERA Nursing Service on Volunteer and Official Agencies*

RUTH E. METTINGER, R.N.

Director of Public Health Nursing, State Board of Health, Jacksonville, Fla.

FORTUNATELY the State Board of Health has had the full control of the ERA Nursing Service. This has prevented duplication of work. One can readily see the possibility of friction and the lack of coöperation if it had not been under proper supervision.

Due to lack of funds for the past 3 years, the Division of Public Health Nursing has not been conducting a generalized program and supervising the nurses employed by volunteer agencies and by cities and counties; therefore, has not received monthly reports from these nurses employed by the local organizations. Prior to the establishment of the ERA Nursing Service the list of those employed in the state was incorrect and incomplete. A survey was made to determine the number of organizations employing nurses. As a result of this survey, it was found that a total of 91 nurses were employed in the state by:

- 4 Red Cross
- 1 U. S. Naval Air Service
- 5 Full-time in County Health Departments
- 7 Metropolitan
- 4 Crippled Children's Commission, financed by the American Legion
- 2 Junior League and Kiwanis Club
- 1 Tuberculosis Association
- 59 Cities, counties, and school boards
- 1 Gulf Life Insurance Company
- 7 Industrial

It is a pleasure to speak of the relationship between the state ERA Nursing Service and the city, county, and volunteer organizations. In Florida we have so few full-time health departments and so few one nurse services, it hardly seems fair for us to compare the ERA Nursing Service with that of other states where the ERA nurses can work under the supervision of a trained health officer. Furthermore, time has not allowed us to judge the effect of the ERA Nursing Program on the permanent services. Because of our knowledge of the work in the state there has been no overlapping or interference in any way with the volunteer or official agencies, but the ERA has filled a definite need which for lack of funds or perhaps because sufficient influence had not been brought to bear on appropriating officials, had not been met by the permanent services.

If under the proper supervision, there is no reason for any organization to look at the ERA Nursing Service with fear and trembling—wondering how it will function and whether it will disrupt and antagonize the agencies with which the lone nurse as well as the units have established satisfactory relations.

Recently when the program had to be cut, it was interesting to note the requests from the various counties pleading for their nurse to remain. Again, when the program had to be changed from FERA to WPA, several of the counties appropriated funds or transportation so that the project could be passed. In the counties where there

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

is no permanent organization the ERA Nursing Service had developed a health consciousness and assisted in promoting health units, which we hope will materialize when Security Funds are available.

Where advisable, nurses were assigned to health departments, but were visited weekly by the District Supervisor of Nurses, who was well trained in public health, so that the State Board of Health would be in constant touch with the work. The nursing services in 2 of the large city health departments were utilized to give training and experience to the ERA nurses. After this training each nurse was placed by herself in a district dividing the territory with the nurse previously employed by local agencies. In a community where a public health nurse was already employed and it was not practical to divide the territory, the ERA nurse confined her activities entirely to ERA clients carrying on a generalized public health nursing service with the family. With 3 organizations in Duval County—City Health Department, Metropolitan Life Insurance Company, and Gulf Life Insurance Company—all employing nurses, one can readily see the duplication if a plan had not been worked out and frequent conferences held with the supervisors of each service.

Monthly meetings were held with all public health nurses, and while their primary purpose was to discuss articles in various professional magazines and the newer methods in public health, they gave all an opportunity of becoming acquainted, which made for a better understanding of the work.

During the past few years the public health nurses have for the most part confined their efforts to school work, to the neglect of the prenatal, infant, preschool, and classes in home hygiene and care of the sick. Where we found this to be the case, the ERA nurse carried on a more intensive maternity program, and conducted home hygiene classes. The classes have been or will be conducted in practically every county in the state, affording a means of teaching the parents the care of the sick in the home and how to meet simple emergencies, thus decreasing the number of necessary home calls for the nurses.

Not until this service was developed, did the public health department give any bedside nursing, which even now is given for the purpose of demonstration only.

There was no Visiting Nurse Association in the state. For the most part practising physicians and health officers were unfamiliar with this type of work, and the health department did not consider it part of its program, but with the sympathetic understanding of our state health officer toward the nursing service, we were able to give the public a service never before rendered in Florida. As a result, one permanent Visiting Nurse Association has been organized and is ready to function when ERA is discontinued.

To build for the permanency of the nursing program, public health nursing councils of lay people have been organized. In counties where there was an active Red Cross committee or tuberculosis committee, having no special project, they were asked to sponsor the nursing service. In many instances this has been carried out and developed a stronger organization than had existed in the past. The Loan Closets, which have been established in the majority of the counties, have been developed by these public health councils, and articles have been supplied by various organizations. The community has found that this fills a great need among the poor patients and is a source of satisfaction. Where public health councils had been established prior to the ERA service, we have asked if the

nurses could attend the monthly meetings and submit reports just as the permanent nurses did. This was done for 2 reasons—so the people in the community could see there was no duplication of work and so the permanent nurse could hear the report of the ERA nurses, at which time a conference would be held in regard to the work of both services. They have proved very helpful both to the ERA and permanent nurses and have enhanced the value of their work.

Few medical advisory committees had been organized in the state, probably due to the fact that the doctors had taken for granted the work of the nurses, and the nurses had failed to ask for the appointment of advisory committees; but because the majority of the ERA nurses were unfamiliar with public health nursing and a certain amount of bedside nursing would be given, the presidents of the local medical societies were requested to appoint these committees and approve standing orders, which were drafted somewhat after those of the N.O.P.H.N., but modified to suit the local situation.

Monthly small district institutes were held by the district supervisors for the purpose of familiarizing the ERA nurses with the work. The permanent nurses contributed to the institute programs giving demonstrations and discussing various phases of public health nursing. Larger district institutes were conducted by representatives from national organizations which both permanent and ERA nurses attended.

Our main object was to coöperate with all existing agencies and serve the people to the best of our ability. Several separate nursing projects were proposed, but fortunately, through our state health officer, they were directed along the proper lines and kept under the supervision of the State Board of Health. The ERA Nursing Service under the State Board of Health has served well the purpose for which it was established, namely, to give employment to nurses in need, and give bedside nursing to relief clients; furthermore, it has supplemented in a large way the public health nursing programs of the State Board of Health and other agencies.

Without additional personnel, the permanent organizations would have been unable to give proper nursing supervision to the many ERA projects that were promoted, such as nursery schools, canning factories, mattress factories, etc., all of which needed public health attention.

Because of their previous training and experience the regular staff nurses were made supervisors and it became their duty to instruct the ERA nurses in the proper procedure of conducting a generalized program, which included the supervision of midwives.

We should look upon all public health nurses, both permanent and ERA, as members of one happy family, all working toward the same goal.

Tuberculosis Studies in Tennessee*

A Clinic Study With Reference to Epidemiology Within the Family

H. C. STEWART, M.D., D.P.H., F.A.P.H.A., R. S. GASS, M.D., AND RUTH R. PUFFER

Epidemiologist; Clinician, Tuberculosis Study; and Statistician; State Department of Public Health, Nashville, Tenn.

PAPERS have appeared from the Tennessee Department of Public Health which bear the general title, "Tuberculosis Studies in Tennessee."[1] This is another of the same series and deals with certain findings in the study of a group of white individuals forming a number of household groups in Williamson County, Tenn.

Williamson County had a population of 22,845 according to the Federal Census of 1930. Of this number about 23 per cent were Negroes. The county is usually considered representative of the rural part of the section known as Middle Tennessee. It has 1 incorporated town, Franklin, which had a population of 3,377 in 1930.

The chief source of income is agriculture, as there are no large industrial concerns in the county. An active and efficient full-time county health department has been in operation since 1921. The intensive study of tuberculosis was begun shortly before 1932, and was made possible through the coöperation of the International Health Division of the Rockefeller Foundation. During the preceding 12 years the number of deaths reported as due to tuberculosis averaged 29 per year, an average annual tuberculosis death rate of 123 per 100,000 population. This rate does not differ materially from that of the state as a whole, and the same trends downward have been seen in Williamson County and in the State of Tennessee.

The group engaged in the study of tuberculosis in the county has endeavored to locate as many cases as possible, and to examine those individuals who are or have been in close association with the cases found. The follow-up activities have been a matter of much importance, and an ever-growing one with the finding of additional new cases with the progress of the study. One of the objectives has been to assemble material which might be useful in planning and conducting programs for the control of tuberculosis in other rural areas.

There are 150 households included in the material used in the present study. Each has or has had in residence a person known, or suspected, to have some form of pulmonary tuberculosis of the adult type. Each of these individuals is the "index case" in the household in which he is recorded. The "index case," as used here, designates that person through whom attention was drawn to the household, and may not

* Read at a Joint Session of the Epidemiology and Public Health Nursing Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

be the only case in the household, or the initial case in the household in point of time. The index case may not be tuberculous, having been examined because of suspected tuberculosis and found to be negative, so far as any demonstrable pulmonary lesion of the adult type is concerned. Although the numbers involved are small, they are statistically significant.

The index cases furnish a group which may be considered a cross-section of those found in carrying on a case-finding program based on obtaining information concerning known or suspected cases of tuberculosis. Such a program is in effect in many parts of the country at present. A matter of particular interest is the result of examination of household contacts of various types of index cases in order to determine which are: (1) infected with the tubercle bacillus, and (2) additional cases of tuberculosis.

The index cases are classified in 4 types:

1. Fatal plus sputum positive—In this group are included those which resulted fatally before the observation of the household, and those which were found to have positive sputum within 1 month of the initial clinic examination.
2. Manifest tuberculosis, sputum negative, or unknown—Those with clinical symptoms and X-ray findings which do not have the appearance of being in an arrested stage, sputum examinations negative, or no sputum available at the time of initial clinic examination.
3. Manifest tuberculosis, arrested—Those with no clinical symptoms suggestive of activity at the time of examination, and with X-ray findings having the appearance of being in an arrested stage.
4. Negative—Those which have no evidence on physical or X-ray examination of any pulmonary tuberculosis of the adult type.

The 150 index cases referred to fall into this classification as shown in Table I. A few in the series have been omitted. Index cases with latent apical tuberculosis and the households in which their records appear were omitted because the numbers were too small to be of statistical significance; those classed as suspicious have been excluded as the diagnosis was regarded as incomplete.

Table I shows the numbers of households in which the various types of index cases were found, the numbers of other members of these households and the numbers of these other members of the households which were examined, and the average number of members of the households.

It is seen that the percentage examined varies somewhat with the severity of the type of index case. It appears that it is possible to examine a larger percentage of the contacts of the more severe types than of contacts with one which has been found negative. This would be expected, but there has been no conscious difference in the effort made to secure the examinations.

TABLE I

CLASSIFICATION OF INDEX CASES, WITH MEMBERS AND EXAMINED MEMBERS OF HOUSEHOLDS

Type of Index Case	*Number of Households*	*Members of Households (Excluding Index Cases)*	*Members Examined*		*Average Number of Members of Households*
			No.	*Per Cent of Members*	
Fatal plus sputum pos.	34	148	127	86	5.4
Mfst., sputum neg. or unk.	34	143	118	83	5.2
Mfst., arrested	34	138	96	70	5.1
Negative	48	243	154	63	6.1
Total	150	672	495	74	5.5

TABLE II

RESULTS OF TUBERCULIN TESTING OF HOUSEHOLD CONTACTS BY TYPE OF INDEX CASE, AND DOSAGE OF TUBERCULIN

Tuberculin Reaction	*Fatal Plus Sputum Pos.*		*Mfst., Sputum Neg. or Unk.*		*Manifest Arrested*		*Negative*	
	No.	*Per Cent*	*No.*	*Per Cent*	*No.*	*Per Cent*	*No.*	*Per Cent*
Pos. to 0.01 mg.	84	80	56	53	26	39	49	37
Pos. to 1.0 mg.	6	6	23	22	19	28	26	19
Neg. to 1.0 mg.	15	14	27	25	22	33	59	44
Total	105	100	106	100	67	100	134	100

The average number of individuals comprising the household of a negative case is somewhat larger than in the other groups.

Table II shows the results of tuberculin testing of individuals in household contact with 4 types of index cases, arranged according to the dosage of tuberculin necessary to produce a reaction. Two dosages were used, 0.01 mg. and 1.0 mg. of old tuberculin, the larger dosage being used only after the smaller had not produced a reaction. The tuberculin was of a lot standardized by the method of Aronson and his coworkers of the Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis.

It can be seen that the percentage of positive reactors decreases with the decrease in severity of contact as indicated by the type of index case in the household; also that the percentage of positive reactors to 0.01 mg. of tuberculin decreases in a like manner. This would indicate that a state of allergy exists in a greater proportion of contacts with the more severe type of index case, and that smaller dosages of tuberculin are necessary to show that this state of allergy exists.

Table III shows the age distribution of individuals tuberculin tested in household contacts of index cases.

It may be seen that 70 per cent of these household contacts reacted to

Total	412	215	52	74	18	289	70	123	30

tuberculin in dosages of 1.0 mg. or less. Of the 412, 52 per cent reacted to 0.01 mg. An additional 18 per cent reacted when 1.0 mg. was used. The percentage of positive reactors to the 2 dosages after early life is approximately parallel, *i.e.*, the use of the larger dosage of tuberculin produces about the same percentage of reactors among those negative to the smaller doses in each age group after the 15–19 year group. In the age group under 5 years, practically all the reactions were to 0.01 mg. In the 35–44 year age group there is a drop in the percentage of positive reactors, which is probably of no significance. In persons 65 and over, there is a greater drop in the percentage of positive reactors, but this group is too small to be of significance. The index cases are not included in this tabulation.

It is quite apparent that there must be differing degrees of exposure within the household, and also varying possibilities of contact with tuberculous individuals outside the household. If individuals under 25 years of age are considered, and divided into 3 age groups, under 5, 5 to 14, and 15 to 24, it would seem reasonable to assume that in the younger age groups, household contact would be of more importance. Using these 3 age groups and the 4 types of index cases, with the result of tuberculin testing as an indicator of infection, Table IV was prepared.

It is seen that the percentage of household contacts under 25 years of age showing positive tuberculin reactions decreases with decreasing severity of the type of index case. These percentages positive are 79, 67, 61, and 47. The gradation downward is most marked in the age group under 5 years, individuals of which have a more circumscribed sphere of activity, largely limited to their own particular households. It is also reasonable to assume that if a severe type of index case exists in the household, the children under 5 years are in more intimate association with it than those in the next age group, 5 to 14 years. In Table IV it is seen that a lower percentage with positive tuberculin reactions is found in the 5 to 14 year age groups (roughly, the school age) than in the infant and preschool age group, under 5 years of age in the fatal plus sputum positive households. This difference is not statistically significant, as only a small number of individuals are included.

The results of clinical and X-ray examination of these household contacts differ from those shown by the tuberculin reaction. It is known that it may require a relatively long period before tuberculous infection can be demonstrated by an X-ray film of the

chest; whereas, the tuberculin test is positive within a short time after infection. After the appearance of lesions demonstrable by X-ray films, they, for the most part, remain visible, while allergy may be lost over a time if the lesion has healed and reinfection has not taken place. Table V shows the findings on roentgenological examination of individuals in household contact with 4 types of index cases, arranged so that the cases of manifest tuberculosis are separated from the others.

The percentage of contacts showing evidence of manifest or latent apical tuberculosis is highest in the contacts of the most severe type of index case, and lowest in the contacts of those classed as negative, and the same is true when consideration is given to the more severe forms of childhood type of tuberculosis. All ages are considered here with no distinction as to younger age groups in which it might be reasonable to suppose that household contact would be of more importance than in the older age groups.

The age distribution of individuals with clinical and X-ray findings are shown in Table VI. These individuals are in contact with the index cases, and have been separated into groups according to clinical and X-ray findings.

The percentage of those in the mani-

Total	194	100	188	99	71	100	453	100

fest, manifest arrested, and latent apical tuberculosis groups increases with age. As would be expected, all the more serious forms of childhood type of tuberculosis are found in the early age groups. Fifty-one per cent of these contacts show evidence of infection; 11 per cent show evidence of manifest or latent apical tuberculosis. With increasing age a greater proportion of these individuals show evidence of manifest or latent apical tuberculosis.

In order to gain more complete information as to the number infected with tuberculosis within any population group, it is necessary to consider results of roentgenological examination in addition to the results of tuberculin testing. It is quite possible for an individual to have a negative tuberculin test, using the generally accepted dosages, and show on X-ray unmistakable evidence of infection, if we accept the appearance of a calcified lesion as evidence. In Table VII the age distribution of individuals tuberculin tested is shown, with further subdivision by X-ray findings of those tuberculin negative. The individuals included are those in contact with the index cases.

The percentage of positive tuberculin reactors rises with increasing age with the exception of a drop in the age group 35 to 44. In the next 2 succeeding age groups the percentage positive to tuberculin is 100, with a drop in the group over 65 years. When the percentages of those negative to 1.0 mg. of tuberculin, but with positive X-ray findings (9 per cent of the total number of individuals) are added to the preceding group, the total percentage of the 2 groups reaches 100 in the 35–44 year age group, and remains at that level. In 21 individuals, 5 per cent of the total, and chiefly in the young age groups, either no X-ray films were obtained, or interpretations of the films were not possible. If those with negative tuberculin and satisfactory X-ray films are considered, there is a total of 102 individuals tuberculin negative, 39 of whom, or 38 per cent, showed evidence of infection on the X-ray film.

It is of some interest to separate the household contacts by the type of index case, and make sub-division of these contacts by the combination of results of tuberculin testing and clinical and X-ray examination. This combination shows in each group those contacts

TABLE VII

Total	98	100	101	101	62	100	111	100

The percentage of individuals showing positive tuberculin and positive clinical findings is highest in that group in contact with the index cases which have been fatal or sputum positive, and lowest in that in contact with the index cases classed as negative. The percentage of individuals with negative tuberculin and no clinical findings increases with decreasing severity of the type of index case. The percentage of individuals with negative tuberculin tests and positive clinical findings also increases with decreasing severity of the type of index case. The numbers in the various groups are small so that differences may not be significant, but it is believed that they are indicative of what may be found with a greater experience.

An attempt has been made to assemble material which would be comparable to data collected in other areas where the case finding methods are similar to those in Tennessee. It seems necessary in most areas to plan definitely this program of case finding and follow-up in families in which cases of tuberculosis are found. The time and personnel necessary for completion in all the details of a comprehensive program are all too limited. It may be possible to modify the program by some such division of cases as has been used in this analysis.

It would seem highly desirable to examine contacts of fatal cases as promptly as possible. A close check should be kept on those individuals in contact with positive sputum cases. If it is not possible to follow up all cases and their contacts, certainly this group and their contacts should be given first preference, and usually concentration of effort is needed.

The cases classed as negative index cases should require very little follow-up. A rather complete history concerning the other members of the household will almost always serve to direct attention to any others in the household group who might have significant findings on examination.

Next in importance to the first group mentioned would appear to be the group designated here as manifest tuberculosis, sputum negative, or unknown. Sputum examinations are of value in this group, as it is of impor-

tance to know as definitely as possible the number and place of residence of all sputum positive cases within any given health jurisdiction. It is from this group that many individuals later show positive sputum. The severity of this type of case seems to be somewhat less so far as infection of contacts is concerned, and reëxamination and intensive follow-up activity of case and contacts should be guided to a great extent by the result of sputum examinations. In Williamson County, the number of sputum examinations, and the time interval, are dependent on the recommendation of the clinician. Usually, from 6 to 10 sputum examinations are requested within 1 to 2 weeks, followed by examination twice each month, and with the occurrence of any increase in severity of symptoms.

In the handling of cases designated as manifest arrested, it would seem advantageous to space visitation so that the occurrence of any symptoms of activity could be rather promptly reported and reëxamination arranged.

If, in the course of getting a history of the other members of the households, there are definite indications for examination of any of the other members of the household groups, this should be made, and the classification of the household changed, should more severe types of the disease be found. With very few exceptions, however, the index case represents the most severe type in the household.

A plan of operation of the kind outlined is in use in Williamson County at present with satisfactory results. The time of the nurses is spent to better advantage; it is possible to keep adequate check on the household groups; a larger case load can be carried; and more time is available for the location of new cases. The necessary reëxaminations can be so spaced as to cut down somewhat on the time and money usually spent on this particular phase of the program.

SUMMARY

1. The results of examination of household contacts of 4 types of index cases have been presented.

2. The group of contacts in households with a more severe type of index case is infected in a larger proportion, and the presence of an allergic condition is more readily demonstrable.

3. This group of contacts shows a higher proportion with the adult type of tuberculosis.

4. The effect of household contact is more demonstrable in the younger age groups.

5. Tuberculin testing of contacts does not identify all individuals who have been infected.

6. It is possible to plan a program of case finding and follow-up, taking into consideration the type of index case in a household, so that more can be accomplished with the same expenditure of time.

The Trained Public Health Engineer in Public Health Departments*

CHARLES GILMAN HYDE, F.A.P.H.A.

Professor of Sanitary Engineering, University of California, Berkeley, Calif.

IT is the frank purpose of this paper to discuss the rôle of the public health or sanitary engineer in public health departments—state, county, district or unit, and municipal—in the United States and to demonstrate the specific value of his services.

Information has been gathered and statistics are presented which show to what extent trained engineers are now employed in various types of health departments. The potential field of opportunity is exhibited and discussed on the basis of county and city populations and the general densities of population development.

Nearly three and a half decades ago Professor William T. Sedgwick[1] defined public hygiene as "the science and art of the conservation and promotion of the public health." He further stated: "It has for its function the prevention of premature death and the promotion of normal life, health, and happiness in communities chiefly by the elimination or amelioration of unfavorable environmental conditions common to many persons or communities either at one time or at different times." Sedgwick's classical statement needs but little revision to reflect completely the present-day attitude toward the true function of sanitation.

In the new edition of Sedgwick's work, prepared by Prescott and Horwood,[2] sanitation is defined as:

> . . . the science and art of the conservation and promotion of the public health through the control of the environment. It has for its object the promotion of health, comfort, and convenience of communities. Accordingly, it deals with those health problems that are common to groups or communities, such as water supplies, sewerage and drainage, refuse collection and disposal, milk supplies, food supplies, restaurant and food store sanitation, ice supplies, air conditioning, lighting, school sanitation, roadside sanitation, sanitation of swimming pools, sanitary drinking facilities, street cleaning, parks and playgrounds, and the control of insects, rodents, odors, noises, obnoxious gases, and other nuisances and dangers to health.

It is of course obvious that the control of man's environment, whether it be in densely populated communities or in sparsely settled rural areas, in so far as such control reduces preventable disease, conserves life, or makes living safer and happier, is a public health enterprise, interpreted broadly, and is therefore a function of any appropriate public health agency.

Reflection perhaps, and experience assuredly, will indicate that in its physical aspects the control of the environment is largely an engineering matter; that is, it falls within the scope of the activities of engineers specifically trained and experienced in sanitation. Such engineers are now being more and more generally called public health en-

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

gineers. Public health engineering may perhaps thus be said to represent the broadest possible conception of the older and original term sanitary engineering.

Among the score or more of activities listed by Prescott and Horwood as within the scope of sanitation, currently viewed, it will be seen that a very considerable number are almost purely of an engineering character and that in the solution of the problems presented by the other undertakings, the engineer's services can be of very distinct value.

The newer appreciation of the value of the services of the public health engineer, in collaboration with other trained workers in public health units, was expressed by Herbert Clark Hoover who, while President of the United States, addressed this Association at its opening session on October 24, 1932, at the Sixty-first Annual Meeting held in Washington, D. C. In the course of his remarks he said[3]:

> As a result of this experience in the flood area [the Mississippi River flood of 1927] I later called a meeting of public health officials and suggested the development of a stronger health service. Out of the conferences which were called as an outgrowth of this meeting, there evolved the idea of the most effective means of strengthening the public health service in harmony with the spirit of our American institutions. By this, I mean the idea of the county health unit. That is, that every county in the United States should set up for itself, as its minimum health organization, a unit consisting of a doctor, a sanitary engineer, and a trained nurse. These units were established in 100 counties in the flood area, and the extraordinarily successful results of their work confirmed the wisdom of the plan. The public health in these counties for 18 months after the flood was so much better than it had been in the 18 months before the disaster as to prove an object lesson in what could be done by organized public health work.

It may be appropriate to remark in this general connection that the problems of environmental control, whether in urban or rural areas, and particularly in the former, are so complex and technical that, to quote from Barron,[4] "the work of the uneducated, untrained and undirected sanitary inspector no longer meets the needs of the present social order."

TYPICAL PROBLEMS AND ACTIVITIES IN ENVIRONMENTAL CONTROL

Environmental control or sanitation, from the standpoint of this discussion, may perhaps be divided into 10 classes or categories of activities, as follows:

1. The quantitative and qualitative control of the air supply
2. The quantitative, sanitary and esthetic control of the water supply
3. The control of the milk supply; production, transportation, pasteurization, sale and handling
4. The control of other food supplies; production, transportation, preservation, sale and handling of raw food products; canning; refrigeration
5. The control of liquid wastes: sewage, trade or industrial wastes; sewers, drains and treatment plants; ultimate innocuous disposal
6. The control of solid wastes: collection, transportation, treatment and disposal of municipal refuse, including garbage, rubbish, ashes, street sweepings, night soil, dead animals
7. The control of the animal and insect carriers of infection: rodents, dogs, goats, cattle, hogs, etc.; preventive and palliative measures against flies, mosquitoes, fleas, lice, ticks, etc.
8. The provision of environmental cleanness: street cleansing; dust, soot and smoke control; swimming pool sanitation; street paving; camps and camp grounds
9. The provision of sanitary conditions in factories, shops, schools, churches, theatres and houses
10. The control of nuisances and other unsatisfactory conditions including odors, obnoxious gases, excessive noise, and the like

ENGINEERING ASPECTS OF THE CONTROL OF THE AIR SUPPLY

The air supply is of significance both from the qualitative and from the quantitative standpoints. The qualitative problem presents itself both in-

doors and, in densely developed communities, out-of-doors as well. The quantitative problem is one of confined spaces only.

The qualitative problem refers to the condition and character of the air supply as related to temperature, humidity, foreign gases, dust, soot, and smoke. Of the 6 qualitative features just named, all are of concern and are practically controllable, within confined spaces. The 3 last named, and perhaps foreign gases, also, to a certain extent, are of concern in outdoor air and are to a reasonable degree controllable.

Air conditioning, as this term is employed today, comprehends the cleansing of the air by washing and/or filtration, its humidification or dehumidification, as the case may be, and its temperature adjustment to insure comfort for any stated or fixed degree of humidity. It involves air movement, also, and, to be satisfactorily performed, all of these conditions, as required, must be provided simultaneously.

Dust, soot and smoke, and poisonous gases such as carbon monoxide, are all controllable in degree at a cost. The several respective procedures in such control involve the paving and cleansing of streets, the effective combustion of fuels, adequate ventilation, suitable industrial processes and methods, and the use of dust precipitation or retention devices in connection with chimneys and flues of boiler plants and of dust-producing industries.

The effective combustion of fuel in industry may involve some capital outlay; but the saving in fuel will frequently offset all of the required costs and pay a handsome financial dividend in addition, not to mention the dividend of a vastly improved environment. The effective combustion of fuels (coal, wood, oil) in houses (residences) is not a simple or readily controllable matter. For one thing, too many persons and too many different sorts of people are involved.

Industrial sanitation, among other things, is concerned with the control of industrial processes and methods, whereby dangerous procedures may be eliminated, and poisonous and obnoxious vapors and gases, dust, etc., may be rendered harmless by removal, eradication, or neutralization.

The dust problem is one of significance because the inhalation of air heavily loaded with dust may and usually does, if continued over considerable intervals, produce a mechanical clogging of the lung tissues and passages. Certain types of dust produce very definite physiological derangements and diseases, such as silicosis, pneumoconiosis, lead poisoning, etc. Two sources of dust are to be recognized: those which are of the exterior and those which originate in enclosed spaces. Exterior sources of dust are streets, vegetation, and chimneys, flues, etc., ejecting smoke and soot as well as mineral dusts. Interior sources of dust are the wear and attrition of floors and the dusty trades or processes.

The dusty trades and processes are very numerous in our modern industrial world. Among them may be named the following: carding of wool and flax; grinding of metals and minerals; milling of wheat and other grains; crushing of stone, coal, and other minerals; manufacture of cement and other finely divided or ground products; sawing and planing of wood and wood products; polishing of a myriad of articles; weighing and sacking of powders and other dusty products; glass manufacture; street and indoor sweeping by brooms; sorting of wool, rags, etc.

Artificial ventilation concerns itself with public buildings in which great numbers of people congregate, such as

schools, churches, theatres, etc. It is also required for all long vehicular tunnels wherein large numbers of automobiles may be in transit at one time. It may be required for large garages which are not or cannot be adequately provided with direct window ventilation.

Some of the air supply problems and general control procedures have been outlined with a view to demonstrate that they are for the most part physical and mechanical in their nature and that they fall therefore within the field of engineering. Some of them are highly technical and involved, requiring special aptitude, training, and experience even for the engineer. The public health engineer in health departments will find many air control problems in which he must act in an advisory or even a directing capacity, particularly in populous areas, and, among these, especially in industrial districts.

ENGINEERING ASPECTS OF THE CONTROL OF THE WATER SUPPLY

The modern water works system must be dependable from the standpoint of physical safety; it must be able to yield an abundant, unfailing supply; and this supply must meet rigorous sanitary and esthetic standards. With the generally increasing pollution of both surface and sub-surface sources, the production of an uninterruptedly safe and satisfactory supply frequently becomes a very difficult matter. Important as it is that water supplies shall be free from all pathogens, and virtually free from all bacteria, that is not enough. To meet present-day requirements, turbid waters must be made brilliantly clear; hard waters must be softened; aggressive waters must be hardened or adjusted with respect to their hydrogen ion content; colored waters must be decolorized; tastes and odors must be removed, together with excessive iron, manganese, and other unwanted substances.

Preventive measures must oftentimes be exercised to restrict pollution, or the growths of plankton, or discoloration, or the causation of other unsatisfactory conditions amenable to control. In some cases the water sources have become polluted to such an extent with sewage and trade wastes that their purification for water supply purposes becomes in effect a salvage of sewage.

The works and procedures required to develop, transport, distribute, and treat water supplies are all of an engineering character. The problems presented frequently demand the highest skill and experience in their solution. In meeting the more difficult problems of treatment the engineer collaborates with the chemist, the bacteriologist, and other technical specialists.

It is the function of health departments to advise with respect to water quality problems and to exercise general supervisory powers to the end that the public health and comfort may be vouchsafed. The water supply is one of the most fundamental of public services and, because of its potentialities as related to disease, it is of extraordinary concern to health departments. State and county departments should maintain rather constant supervision over the water supplies coming within their jurisdiction, particularly the smaller ones whose personnel and equipment are limited. Such supervision should comprehend systematic inspections on the part of the public health engineering staff, with adequate sampling and laboratory checking.

In illustration of the water supply problems faced by a single county health department, that of Westchester County, N. Y., Barron[4] stated that there are in that county 23 sources of supply and 41 public distribution systems, a number so large that it would be difficult if not impossible for a state department of health to maintain

supervision without local engineering assistance. Improvements in equipment and operation of chlorination plants were found to be necessary in most cases. Corrosion problems were acute in several systems. Other important responsibilities were the prevention of pollution on watersheds, the promotion of improved public supplies in replacement of inadequate, unsuitable private supplies, and the improvement of private supplies which were found to have logical reasons for continued existence.

Fuller[5] calls attention to the importance of establishing a consistent policy with respect to all water supplies in any public health administrative district because of the frequency of changes in the personnel of the local water supply management boards.

ENGINEERING ASPECTS OF THE CONTROL OF THE MILK AND FOOD SUPPLIES

The mechanical problems of transportation, pasteurization, canning, and refrigeration of milk and other food products are essentially engineering in their nature and should be attacked and solved from such a viewpoint. Other correlated problems such as are referred to below, are not, of course, in the category of engineering activity, *per se*. Yet the methods of approach and the procedures utilized should be of the same order in respect to rationality and regimentation.

Referring again to the Westchester County experience, Barron[4] states that 35 health officials in that district had been issuing permits for the sale of milk. None of these officials had been able to examine the various milk supplies or to apply adequate and proper technical supervision to either the local or distant milk sources. The county health department established a balanced and effective control of the entire system of milk supply, comprehending the necessary inspections of all dairies, the veterinary examination of all herds, the making of bacterial counts of the supplies from all producers, and the systematic inspection of all tributary shipping stations, of pasteurization and bottling plants, and of distributing stations.

Health departments must develop sanitary regulations governing food-selling establishments and must see that these are enforced. Meat coming from sources other than those regularly inspected and approved by federal agencies should be inspected and stamped by the local authorities. The protection of all foods from insects and dust and from promiscuous handling in meat and fish markets, vegetable shops, delicatessen stores, bakeries, and the like, must be insisted upon and vouchsafed by systematic inspections.

ENGINEERING ASPECTS OF THE CONTROL OF SEWAGE AND INDUSTRIAL WASTES

The collection and innocuous disposal of a community's liquid wastes—sewage, trade wastes, and the like—is an absolutely fundamental necessity and a matter of vital consequence to the health and comfort of its people. The proper supervision and control of sewerage systems and sewage treatment and disposal plants ranks in importance with the control of the water, milk, and other food supplies. In this field the problems are almost wholly of an engineering character demanding training and experience of fully as high an order as that demanded by any other exacting public health engineering activity, not excluding water purification. As a matter of fact sewage treatment practice is less standardized, perhaps, than any other activity of the sanitary engineer.

The health authority, with the aid and advice of the public health engineer, can and should determine upon and develop an intelligent, rational public policy with respect to sewage and

trade wastes treatment and disposal. It can and should influence and direct public opinion to the end that suitable and adequate methods and means for treatment and disposal be provided by the responsible authorities. Existing plants should be regularly inspected and samples taken and examined in the laboratory to demonstrate the adequacy and efficiency of treatment. This is especially true of small plants with untrained operators and few or no laboratory facilities. Institutional and private plants generally fall within this category.

The disposal of raw or inadequately treated sewage has very often resulted in a serious contamination of inland streams, tidal estuaries, and even of ocean shores. It has frequently destroyed the esthetic value of water courses and has sometimes caused the water to be unfit even for an industrial use. Bathing beaches have become insanitary and objectionable in appearance. Notwithstanding the great potency of the several agents of self-purification, taken together, it must be clearly recognized that there is scarcely a stream in America long enough to insure complete redemption from the effects of sewage contamination judged by the criterion of safety for drinking purposes. It is obvious that the treatment of sewage may be necessary, therefore, in order to maintain the redeemable or esthetic character of any body of water into which it may be considered expedient to discharge the effluent. The degree of treatment, *i.e.,* the extent of improvement provided, must be determined by the conditions of each case. The kind of treatment will be largely determined by the degree of improvement demanded by these conditions considered in conjunction with physical and economic considerations. The problem is by no means simple. It demands skill and judgment born of experience.

ENGINEERING ASPECTS OF THE CONTROL OF REFUSE COLLECTION AND DISPOSAL

The municipal refuse problem has both a sanitary and an esthetic significance. Each is important. The most significant element of municipal solid refuse is the garbage. Inasmuch as this material constitutes a much-sought-after food for flies and rats, and provides an excellent breeding place for the former, its sanitary significance becomes obvious. Garbage, moreover, is highly putrescible and its decomposition gives rise to obnoxious odors. Its esthetic significance, therefore, becomes apparent. Some of the materials comprehended by the term rubbish, such as foul, dirty rags, have a public health significance. Rag sorting, for example, is recognized as one of the dangerous trades. Heaps of rubbish afford a haven for rodents and in that respect are to be reckoned with from the public health standpoint.

The community refuse problem is ordinarily presented in 4 distinct and more or less independent phases; namely, (1) the storage of the refuse, with or without segregation, on the householder's premises; (2) the collection of the refuse by the accredited agency; (3) the transportation of the refuse through the streets of the community; and (4) the proper disposal of the refuse as a whole (mixed refuse) or in separate portions (classified refuse).

The problems thus presented are complicated. In their physical aspects they are for the most part in the sanitary engineer's particular field of activity. Their solution represents an important item in the practical control of man's urban environment. Too often these problems have been relegated to untrained, disinterested administrators.

It is now being proposed in some quarters that the garbage of the community be ground up either by the individual householders or by the com-

munity at central stations, and disposed of by discharge into the sewers. Such disposal will add enormously to the organic matter load carried by the sewage and will place that burden upon the treatment plant or receiving stream. A definite policy with respect to such a procedure should be determined upon by the responsible authorities, including the health agency. It is a highly involved technical matter and should be so considered.

ENGINEERING ASPECTS OF THE CONTROL OF ANIMAL AND INSECT CARRIERS OF INFECTION

In the control of the animal and insect carriers of infection the public health engineer coöperates with the epidemiologist, the entomologist, and the veterinarian.

The carriers involved are: (a) man himself as the chief carrier of infective agents of mankind; (b) all animals subject to rabies; (c) rodents subject to fleas and bubonic plague; (d) animals which carry ticks, or are subject to tick infections; (e) hogs which convey *trichinella spiralis;* (f) cattle and hogs which are the intermediate hosts of *taenia saginata* and *taenia solium;* (g) cattle infected with bovine tuberculosis; (h) goats, cows and hogs which convey the organisms causing undulant fever; etc.

The principal insects involved are: (a) flies, biting and nonbiting, active and passive carriers of any and all pathogenic bacteria which cause intestinal and other diseases in man, including typhoid fever, cholera, bacillary dysentery and tularemia, together with the infective forms of many of the protozoa; the cysts of *Endameba hystolytica,* and the eggs of helminths which do not require an intermediate host, such as *ascaris lumbricoides* or *Hymenolepis nana;* (b) mosquitoes which are responsible for yellow fever, malaria, dengue and filariasis (bancrofti); (c) fleas which convey plague (*B. pestis*); (d) lice which convey the organisms of typhus, trench and relapsing fevers; (e) ticks which convey the organisms of relapsing fever, Rocky Mountain spotted fever, and tularemia; (f) sand flies or moth midges conveying the organisms of pappataci fever, and *Leishmania denovani,* the etiological agent of kala-azar (Leishmaniasis); (g) bedbugs, roaches, and ants which, while perhaps not directly concerned with the dissemination of the causative organisms of specific infectious diseases, are nevertheless unwelcome inhabitants of man's environment.

Some of the more important preventive measures available for the control of the mosquito and mosquito-borne diseases, such as the elimination of breeding places by the draining of swamps and shallow pools, the rectification of stream beds and channels, the filling of small holes and pools which cannot be drained readily, and the removal of vegetation from and the steepening of banks of ponds and streams, also the oiling of undrained or undrainable water surfaces at sufficiently frequent intervals, are all of an engineering character and can best be accomplished under the direction of the trained public health engineer.

Other preventive measures and those which are palliative for the control of the mosquito, as well as other insects and animal vectors, may well be conducted by engineers trained and experienced in such work.

ENGINEERING ASPECTS OF THE PROVISION OF ENVIRONMENTAL CLEANNESS

The major problems concerned with the production and maintenance of environmental cleanness are physical and mechanical in their nature and hence within the scope of the sanitary engineer's activities. Among the acts

which bring about or conserve cleanness are such obvious undertakings as the provision of street paving and the operation of street cleansing. The control of dust, smoke and soot is of fundamental importance from the standpoints of both health and comfort. Because of its relation to their comfortable use, even though the public health may be involved only secondarily, it is the duty of health departments to insist upon the continued cleanliness of all publicly used buildings, including comfort stations, and of all recreational facilities and areas.

Swimming pool sanitation has been included in this group of activities having to do with environmental cleanness although it is often set apart as an independent item because of its public health implications. Public swimming baths have already become a nationwide institution. Their numbers will doubtless continue to increase for some years to come. Swimming pool regulation has therefore become a significant public health measure in view of the great numbers of patrons involved and the danger of disease attendant upon the use of improperly designed, constructed, and operated baths. In the provision and maintenance of a suitable and satisfactory water supply, problems of filtration, plankton control, disinfection, water heating and circulation, etc., are all encountered. Other features of sanitation are vitally important, also, and demand constant vigilance. Swimming pools should be operated under permits and regulations of the resuponsible health department. They should be regularly inspected and samples of the water should be systematically collected and subjected to laboratory examination.

Health departments should assume responsibility for the training of operators and this training should be akin to that demanded for water works operators.

ENGINEERING ASPECTS OF THE PROVISION OF SANITARY CONDITIONS IN BUILDINGS

It is or should be the duty of health departments to regulate and inspect all plumbing, heating, ventilating, air conditioning, dust control, and other equipments and installations which affect the health, comfort, and general well-being of workers in factories and industrial plants of all kinds, of children in the schools, patrons of theatres and other meeting places, as well as residents in private dwellings, the last particularly with respect to plumbing and gas appliance installations. Many of the problems presented are of an engineering nature.[6] The control procedures should be directed by experienced persons gifted with common sense and the power of rational appraisement.

ENGINEERING ASPECTS OF THE CONTROL OF NUISANCES

Many of the nuisances occurring in urban areas arise out of a failure to control properly the environmental conditions briefly outlined above. In particular, nuisances are caused by excessive numbers of various sorts of insects; by odors from sewerage works, polluted streams and shores, refuse collection, transportation and disposal procedures, industrial plants, and the like; by obnoxious vapors and gases; and by excessive noise. Here again, the problems are frequently of a sort which demand the skill and training of the public health engineer in their solution.

SCOPE OF THE PUBLIC HEALTH ENGINEER'S TRAINING

Courses for the education and training of sanitary and public health engineers have been introduced and developed in a considerable number of the universities and larger technical colleges or schools in the United States.

Probably all degrees of training are provided therein, from the highly specialized courses giving comprehensive instruction in the art of sanitation, in addition to the basic curriculum of civil engineering, to those which might be more properly classed as almost strictly civil engineering with a limited amount of stress placed on water supply and sewerage problems only.

There can be no question that the ideal course should comprehend fundamental training in inorganic, organic, and physical chemistry, in bacteriology, microscopy, zoölogy and entomology, together with the more usual courses in water supply and sewerage engineering, and in water and sewage treatment. In addition there should be competent courses in water and sewage analysis and general laboratory technic, together with studies in the field of general sanitation.

The scope of the ideal public health engineering course has been suggested, it is believed, by the foregoing brief survey of the engineering aspects of environmental control. It is obvious that expertness or proficiency in all of these matters cannot be acquired at all in most institutions or, for that matter, in any institution within the usual time allotment. But a thorough grounding in the more essential principles and procedures can be acquired if the facilities are offered. Upon such a basis experience will soon develop the necessary proficiency if the engineer is of the right sort and remains a student while he practices his profession.

STATISTICAL REVIEW OF THE EMPLOYMENT OF PUBLIC HEALTH OR SANITARY ENGINEERS IN PUBLIC HEALTH DEPARTMENTS IN THE UNITED STATES

In 1934 the writer prepared a questionnaire which was sent to all state departments of public health, by which it was hoped to determine for each state:

1. The number of trained sanitary or public health engineers employed in the division or bureau of sanitary engineering of the state department of public health
2. The number of counties and municipalities which employ such engineers in their public health departments
3. The number of sanitary or other districts which employ such engineers and for what purposes
4. The number and names of counties having well organized, full-time health departments
5. The number and names of cities having well organized, full-time health departments

In those cases where the state department of public health had a division or bureau of sanitary engineering, the questionnaire was sent to the chief engineer or director; otherwise to the chief administrative officer of the board. Replies were promptly received from all but 7 of the 48 states. A second inquiry brought replies from 5 additional states; and a third, 1 more; only 1 state has failed to furnish the information desired.

In addition to the information requested, each state sanitary engineer was asked to express his judgment with respect to the lower population limit at which sanitary or public health engineers should or might reasonably be expected to be employed in the health departments of: (1) cities; (2) counties, exclusive of cities having population as great or greater than the lower limit set for (1) cities.

The information thus made available has been prepared in the form of a statistical summary for each state and for the United States, together with certain relevant data concerning the population, area, and population density of each state; the numbers of counties, total, total having populations in excess of approximately 50,000, and total having net populations of approximately 50,000 exclusive of cities having approximate populations of 50,000 or over; and the total number of cities in

each state having populations in excess of approximately 50,000.

PUBLIC HEALTH ENGINEERS IN STATE PUBLIC HEALTH DEPARTMENTS

Beginning with the epoch-making establishment of an engineering department by the Massachusetts State Board of Health in 1886, when Frederick P. Stearns (who later became one of the most distinguished engineers of his time) was appointed engineer to the board, an appreciation of the value of the services of engineers in state departments of public health has gradually been developed. It is no longer questioned that state departments of public health should maintain an engineering bureau and staff. Forty-three states already have engineering bureaus with full-time public health or sanitary engineers and one other state employs such an engineer on a part-time basis. The total number of trained engineers thus regularly engaged is about 190. In addition, several state health departments employ sanitary chemists and operate engineering laboratories, *i.e.*, for water and sewage analysis, primarily.

The statistics presented herein are intended to reflect reasonably normal conditions and, specifically, those of the year 1934. At present (September, 1935) relatively large numbers of engineers, presumed to be trained in public health work, in so far as such are available, are being employed throughout the country as an emergency relief measure. Many of these have been appointed to serve with the U. S. Public Health Service but have been assigned to work with state public health departments on various types of environmental sanitation projects such as sanitary privies, mosquito control, etc. Others are temporarily employed directly by the state health departments, their salaries being paid out of federal funds allocated for the purpose.

Whipple [7] has presented a clear picture of the effective work of the engineers of the Massachusetts State Board of Health from the beginning until about the year 1917.

Tisdale [8] has also given illuminating insight into the work of the state sanitary engineer. He quotes Whipple as having said, "Good advice by the sanitary engineer to cities and towns in the state, is on the whole more beneficial than all the permits, approvals and orders ever issued by a department." With respect to the work of state health departments, Tisdale calls attention to the vital quality of the sanitary engineer's services in matters of water supply and sewerage, sanitary milk production, joint federal and state sanitation programs (including stream pollution control), recreational sanitation, industrial wastes control, swimming pool sanitation, and sanitation legislation. He further emphasizes the salutary fact that the tenure of office of state sanitary engineers has been fairly secure and he cites the cases of a considerable number of engineers whose terms of service have ranged from 2 decades to nearly 50 years.

PUBLIC HEALTH ENGINEERS IN COUNTY OR COUNTY-UNIT HEALTH DEPARTMENTS

While a considerable proportion of our state departments of public health have long recognized the value of the services of sanitary and public health engineers in matters dealing with environmental sanitation, this unfortunately cannot be said with respect to county departments of health. It is only recently that an appreciation of the value of such service has begun to affect the operations of the smaller units of public health administration.

By reason of the multiplicity of village, town, and city governments and their various and ofttimes inconsistent and conflicting regulations, and

furthermore because of the all too common inadequacy of planning, construction and operation of sanitary facilities and the lack of recognition of local sanitation problems, as Barron[4] observes, there are many complications to be overcome in effectively accomplishing environmental control in counties and county health units. For these reasons the services of trained public health engineers, capable of recognizing and directing the solution of the many problems demanding attention and solution, are all the more necessary.

It appears that in the entire United States there are probably less than 25 public health engineers regularly employed in 21 county, county-unit, or district health departments in 10 states. On the other hand, there appear to be between 400 and 500 purportedly well organized, full-time county, county-unit, or district health departments, many if not all of which should enlarge the scope of their activities and increase their effectiveness by establishing bureaus of public health engineering and employing trained personnel.

In the 48 states there are 3,072 counties, of which number 437 have populations in excess of approximately 50,000, and 376 have populations exceeding approximately 50,000, exclusive of cities of approximately that same population.

Thirty-one state sanitary engineers were willing to express an opinion concerning the lower population limit of counties in which sanitary or public health engineers should or reasonably might be expected to be employed in the health departments thereof. These population limits were specified to be exclusive of the aggregate populations of cities having populations of sufficient size to warrant, in their opinion, the employment of sanitary or public health engineers in their own health departments. The opinions varied from "every county" and "every county health unit" to a population of 200,000 in one case, and 500,000 in another. The minimum assigned figure was 10,000. The mean of all of the estimates, expressed in numerical terms, is about 57,000. Exclusive of the two highest figures noted above, the average figure is about 34,000. It would seem to be rational to conclude that every county, county-unit, or district having a net population, as above defined, in excess of 50,000 at most should have the benefit of the full-time services of one or more public health engineers. In areas where the problems of sanitation are for some reason acute, or where the economic status of the population is high, public health engineers should be employed where the population is smaller, possibly much smaller, than the figure just named.

PUBLIC HEALTH ENGINEERS IN CITY HEALTH DEPARTMENTS

The appreciation of the value of the services of the public health engineer in the health departments of cities is apparently even less manifest than in county, county-unit, or district departments. It is also at least as recent. This lack of recognition is amazing in view of the great numbers of environmental sanitation problems demanding attention and solution in practically all urban areas, and particularly, of course, in the larger cities.

This matter has been well stated by Connolly[6] as follows:

> It was not so many years ago when people generally thought of the field of sanitary engineering as one limited to questions of water supplies, stream pollution, trade wastes, and the collection and disposal of garbage and sewage. Engineering methods have proved to be so successful that now they are being applied in many other lines of sanitation and at present the sanitary engineer is called upon to deal also with pasteurization of milk; protection of oyster-growing areas;

problems of housing, such as overcrowding, light, heat, and ventilation; malaria control; plague eradication; destruction of vermin; industrial sanitation; smoke abatement; noise reduction; protection of swimming pools and bathing beaches; special hazards of comparatively recent importance, such as poisoning by refrigerants, by gases and other substances used in fumigation, and by hair dyes, shoe dyes, moth-proofing compounds, etc.; and the abatement of nuisances of many kinds.

The sanitary engineer is or should be also particularly responsible for plumbing installations and cross-connections between the public and private water supplies.

Connolly [6] further states:

The work of the city sanitary engineer is one that touches almost every phase of urban life in some way. The field is constantly growing as new materials and usages are developed. The scope is as broad as man's environment. The necessity for the work will continue as long as man continues to be a gregarious animal and seeks the company of his fellow man. It is truly a task to challenge all that is best in a man and reward him with the knowledge that he is doing his bit to make his city a more healthful, happy, and useful community, and to give to his children a better environment than his own has been. There is no question but that the next decade will see a tremendous development in the sanitary engineering activities in city health departments in all parts of the country, for we are living in an age of engineering achievement. Municipal administrative health officers not provided with such a bureau in their departments are at a distinct disadvantage when dealing with many of the present-day developments, and are now asking their city councils to permit them to follow the example of the United States Government and of so many state health commissioners, in creating an efficient, modern sanitary engineering bureau. The public realizes as never before that in this era of specialization, specialists in this field will do much to make life richer and more enjoyable as well as longer.

The information gathered in connection with this study indicates that there are probably not more than 30 public health engineers employed in 24 city health departments in 13 states. There appear to be approximately 320 well organized, full-time city health departments in the United States, practically all of which should follow the example of such cities as Atlanta, Chicago, Cincinnati, Cleveland, Dallas, Detroit, El Paso, Fort Worth, Jacksonville, Memphis, New York, St. Louis, and Tucson, in enlarging the scope of their activities and increasing their effectiveness by establishing bureaus of public health engineering manned with trained, capable engineers.

In the entire country there are 211 cities having populations of approximately 50,000 or over and some 280 whose populations are 35,000 or over.

Thirty-five state sanitary engineers kindly gave thought to the determination of a lower limit of population of cities in which sanitary or public health engineers should or might reasonably be expected to be employed in the health departments thereof, and expressed their opinions in numerical terms. The assigned figures ranged from a minimum of 2,500 to a maximum of 100,000. The average of the 35 values submitted is about 34,000, or the same as the mean figure for county health departments excluding the two highest figures, as above noted. The average of 24 similar estimates of a lower population limit obtained by the Committee on Municipal Public Health Engineering, Public Health Engineering Section, this Association, is 40,000. The figures submitted range from 5,000 as a minimum to 100,000 as a maximum. It would seem to be fair to conclude that every city having a population of 50,000 at most should enjoy the benefit of the full-time services of one or more sanitary engineers in an organized, properly equipped bureau. In well-to-do communities or those facing acute sanitation problems the lower limit of size for which such services are provided should unquestionably be smaller; in some cases only

a fraction of the population size stated above as a mean of the several estimates. If the supervision of water and sewage treatment plants is also assigned to the health department engineer, the population limit might well be lowered to 10,000 or even 5,000.

SANITARY DISTRICT ORGANIZATIONS

Inquiry was made to determine the number of sanitary districts employing trained sanitary engineers for the conduct of their activities. Such districts are ordinarily charged either with water supply and sewerage undertakings, including treatment, or with mosquito eradication, as the case may be. The information secured indicates that there are at least 32 such districts in 9 states.

FEDERAL SERVICE

No attempt has been made to determine what federal agencies employ sanitary engineers other than the U. S. Public Health Service. In that service the sanitary or public health engineers enjoy the same rank and pay as do the medical officers and are in line for promotion under similar regulations. The total number of engineers now authorized and commissioned is 22, distributed in rank as follows: senior surgeons (senior sanitary engineers), 1; surgeons (sanitary engineers), 15; passed assistant surgeons (passed assistant sanitary engineers), 5; assistant surgeons (assistant sanitary engineers), 1.

It is gratifying to realize that for many years the Service has exerted a stimulating influence with respect to the employment of public health engineers in state health departments and elsewhere and more recently in the health departments of smaller administrative units.

CONCLUSIONS

The environmental control activities which demand or at least would be definitely promoted by the services of trained public health engineers can be placed in 10 categories, as follows: (1) the water supply; (2) the air supply; (3) the milk supply; (4) food supplies other than milk; (5) liquid wastes (sewage, industrial wastes, etc.); (6) solid wastes (municipal refuse); (7) animal and insect carriers of infection; (8) environmental cleanness; (9) sanitary conditions in buildings; (10) nuisances and other unsatisfactory conditions.

The writer has attempted to outline and briefly discuss the engineering aspects of each of these groups of activities and to show in what more or less specific respects the training and experience of the sanitary or public health engineer would be of particular avail. It has been demonstrated, it is hoped, that the number of phases of environmental sanitation in which the services of the trained engineer can be of material worth, is very large. In a not inconsiderable proportion of these undertakings his services are, in fact, well nigh indispensable if the most effective results are to be secured.

It is no longer questioned that state departments of public health should maintain an engineering bureau and staff of trained sanitary engineers. Forty-three state departments are already so organized and employ at least one full-time engineer. Another state employs a sanitary engineer on a part-time basis.

It is only recently, and as yet in a pitifully small way, that appreciation of the value of such service has been recognized and expressed by the employment of public health engineers in the smaller units of public health administration: county, district or unit, and municipal.

Summarized statistics of employment of public health engineering services in these units have been presented in the foregoing discussion.

There are 22 sanitary engineers regularly commissioned in the U. S. Public Health Service.

It is apparent that there is an enormous potential field for the useful work of the public health engineer in federal, state, district or county, and municipal public health departments. The most effective progress of environmental sanitation throughout the United States and the welfare of the engineer are both deeply concerned.

RECOMMENDATION

The writer recommends that the Committee on Scope of Technical Activities of the Public Health Engineering Section of this Association prepare a circular which can be sent to the responsible administrative officers of all state, county, county-unit, district, and municipal health departments outlining the character and value of the services of the trained public health engineer in such organizations.

ACKNOWLEDGMENTS: The writer wishes to express his obligation to the state sanitary engineers and medical directors of state public health departments who have so kindly furnished the statistical information concerning the employment of public health engineers in the several types of administrative units which have been discussed and concerning the names of counties, county-units, and cities which maintain well organized, full-time health departments.

Several of the state sanitary engineers offered very helpful criticisms and suggestions, particularly Bair, Boyce, Ferguson, Morton, and Stevenson. The writer is also indebted to N. M. Fuller and Professor Thorndike Saville for valuable comments and to William H. Cary, Jr., Chairman, Committee on Municipal Public Health Engineering, this Section, A.P.H.A., for useful data concerning the employment of public health engineers in municipal public health departments in the United States.

Life Expectation

IN England and Wales in 1875 the average expectation of life of males at birth was 41 years and of females 44 years.

Now let us see the position today. The average expectation of life of males at birth is 57 years and of females 61 years. This is a remarkable change. In the short period from 1875 to 1935 the length of life in males has increased by 16 years and the length of life for females has increased by 17 years.—James Fenton, M.D., Public Lecture to the South African Health Congress, *J. Roy. San. Inst.*, May, 1936, p. 642.

Detection of Shedders* of Streptococci Responsible for Infectious Bovine Mastitis†

W. N. PLASTRIDGE, PH.D., AND E. O. ANDERSON
Storrs Agricultural Experiment Station, Storrs, Conn.

DURING the past few years increased interest in the control of bovine mastitis has caused a corresponding increase in the study of streptococci commonly found in freshly drawn milk. In order to secure further data on the characteristics of these organisms and their possible relation to chronic bovine mastitis, milk samples were collected aseptically from each quarter of lactating animals in 15 different herds. The samples were examined for evidence of mastitis and the presence of streptococci. Cultures of streptococci obtained from 970 samples have been isolated and studied. It is the purpose of this paper to describe the characteristics of these organisms, their relation to other laboratory evidence of mastitis, and the relative efficacy of different methods in detecting shedders of streptococci.

METHODS

The following determinations were made on each sample: physical appearance, reaction to bromthymol blue, leucocyte count, sediment volume, types of colonies produced on blood agar plates, and the presence or absence of chains of spherical cells in incubated portions of the sample. Streptococci, when present, were isolated and the following properties determined: hemolysis on cow's blood agar, reaction in litmus milk, ability to hydrolyze sodium hippurate, ability to reduce methylene blue milk (1:5,000), and ability to produce a distinctly acid reaction with Andrade's indicator in serum broth containing lactose, mannitol, inulin, raffinose, arabinose, and salicin.

CHARACTERISTICS OF STREPTOCOCCI STUDIED

By comparing the biochemical properties of each culture with the presence or absence of laboratory evidence of mastitis at the time and after the cultures were isolated, it was found that the different streptococci studied could be placed in one of three groups: Group A, designated as *Streptococcus mastitidis,* which appears to be the principal causative agent in infectious chronic bovine mastitis; Group B, which appears to be associated with a relatively mild form of mastitis from which animals usually recover; and a group composed of various types of saprophytic streptococci commonly found in the mouth, on the skin, and in the excreta of cattle. The principal

* The term "shedders" is used to designate lactating animals which eliminate the organism in question through the milk.

† Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

S⁴-S BOVIS AS DESCRIBED BY SHERMAN AND STARK (19)

differential properties of each of the three groups are shown in Figure I.* Cultures classed as saprophytes are designated as S^1, S^2, S^3, and S^4.

Streptococcus mastitidis (Group A)—Members of this group are identified by the following characteristics: they acidify and coagulate litmus milk with partial reduction of litmus; hydrolyze sodium hippurate; fail to produce a distinctly acid reaction in serum broth containing mannitol, inulin, raffinose, arabinose, and sorbitol; and do not, as a rule, reduce methylene blue milk. Reactions in trehalose, salicin, and glycerol broth were found to be variable.

Streptococcus mastitidis (Group A) differs from *Streptococcus pyogenes* by producing surface colonies on blood agar that are surrounded by a narrow band of partial hemolysis, which is in marked contrast to the wide band of complete hemolysis usually produced by colonies of *Streptococcus pyogenes*. The mastitis organism hydrolyzes sodium hippurate and is a high acid producer in dextrose broth. As a rule, the reactions of the two organisms in litmus milk differ also; the human pathogen produces an acid reaction without coagulation and without reduction, while the animal pathogen causes an acid reaction with coagulation and partial reduction of the litmus.

Group B—This group is not as well defined as Group A. Members of Group B differ from those of Group A by fermenting mannitol, by usually reducing methylene blue milk, and by fermenting either inulin or raffinose, or both.

Saprophytes—This group contains various types of saprophytic streptococci which have been described[2, 3, 4] as common inhabitants of the mouth, skin, and excreta of cattle. While these organisms differ considerably in their biochemical properties, they may be distinguished from *Streptococcus mastitidis* (Group A) and the organisms in Group B, by their reaction in litmus milk and by their fermentative properties in carbohydrate broth.

RELATION OF DIFFERENT TYPES OF STREPTOCOCCI TO MASTITIS

Cultures obtained from samples drawn from individual quarters of animals in 15 experimental herds were

---

* Figure I has been described previously in Storrs Experiment Station *Bulletin 195*.[1]

identified by the use of the diagram shown in Figure I. The milk samples were also examined for other evidence of mastitis; namely, a leucocyte count of 500,000 or more cells per c.c., sediment volume of 0.5 per cent or more, and a positive reaction to the bromthymol blue test. The number of cultures placed in each of the three general groups described, and the relation of the cultures to other evidence of mastitis, are shown in Table I.*

TABLE I

RELATION OF DIFFERENT TYPES OF STREPTOCOCCI OF BOVINE ORIGIN TO EVIDENCE OF MASTITIS

Source	Number of Cultures	Identified as: Group	Identified as: Number	Number Associated with Other Evidence of Mastitis	Number from Apparently Healthy Quarters
15 experimental herds	970	A	828	809	11(8)*
		B	56	46	10
		Saprophyte	86	3	83

* No data following time culture was isolated.

Of 970 cultures examined, 828 were placed in Group A, 56 in Group B, and 86 were regarded as saprophytes. Of the 828 Group A cultures, 809 or 97.7 per cent were associated with other evidence of mastitis. Forty-six of the 56 cultures placed in Group B were also from quarters showing evidence of mastitis. Only 3 of 86 cultures classed as saprophytes were from diseased quarters. In these instances, it appears probable that streptococci which are ordinarily harmless gained entrance to the affected quarter as a result of a previous injury.

DETECTION OF STREPTOCOCCI RESPONSIBLE FOR MASTITIS

Three hundred and sixty samples of milk collected from the college herd in 2 of the regular bi-monthly tests were examined for the presence of streptococci by 6 different methods. Blood agar plates were inoculated by 3 different methods: (1) streaking with whole milk, (2) streaking with sediment from a centrifuged (10 c.c.) portion of the given sample, and (3) the standard dilution method. Microscopic examinations were made of films prepared from whole milk, sediment from a centrifuged 10 c.c. portion of the sample, and from a portion of the same sample following incubation over night at a temperature of 37° C. The results obtained are recorded in Table II.

Of 79 samples from quarters showing laboratory evidence of mastitis, as revealed by one or several of the tests employed, streptococci were found in 77.2 per cent, when the blood agar plates were streaked with sediment. Blood agar plates inoculated by the usual dilution method were about equally effective. Microscopic examination of films prepared from whole milk and from milk sediment revealed the presence of streptococci in only 3.8 and 8.9 per cent of the samples, respectively.

Microscopic examination of films prepared from incubated milk proved to be the most effective of the 6 methods in detecting the presence of streptococci responsible for bovine mastitis. This method revealed the

* In practice it is not necessary that cultures of streptococci of bovine origin be examined for ability to hydrolyze sodium hippurate, unless the culture is sufficiently hemolytic to suggest that it may be *Streptococci pyogenes*.

TABLE II

DETECTION OF STREPTOCOCCI IN FRESHLY DRAWN MILK SAMPLES

Method Used		*Diseased Quarters* † *Per Cent of Samples Yielding Streptococci*	*Healthy Quarters* *Per Cent of Samples Yielding Streptococci* *
Blood agar plate	Whole milk-streak	60.8	1.1
	Sediment-streak	77.2	2.5
	Standard dilution	76.0	0.7
Microscopic examination	Direct	3.8	none
	Sediment	8.9	none
	Incubated milk	98.7	13.5

* Saprophytic streptococci and diphtheroids producing streptococcus-like colonies on blood agar plates.
† Quarters affected with chronic streptococcic mastitis.

presence of streptococci in 98.7 per cent of the samples collected from animals affected with chronic streptococcic mastitis. Unfortunately, about 13.5 per cent of the samples from healthy quarters also yielded chains of streptococci by this method.

SIGNIFICANCE OF THE FINDING OF STREPTOCOCCI IN INCUBATED MILK

Of 360 samples of unincubated milk used in the comparative tests, 50 failed to yield colonies of streptococci on the blood agar plates, but revealed streptococci by the direct microscopic examination of the incubated samples. Information on the significance of demonstrating streptococci in these samples was obtained by comparing the finding of streptococci with other laboratory evidence of mastitis, and by isolating and identifying the streptococci in the incubated samples. The results are given in Table III.

Thirty of the 50 samples showed no other evidence of mastitis either at the time or immediately following the test. Cultures obtained from these samples were identified as saprophytes. Three other samples that showed no other evidence of mastitis at the time of the test, were from quarters that gave evidence of mastitis 2 weeks later, when cultures obtained from these quarters were identified as *Streptococcus mastitidis* (Group A). Microscopic examination of incubated milk revealed the presence of streptococci in 16 samples that gave other evidence of mastitis, but no colonies of streptococci on blood agar inoculated with the samples before incubation. Seven of the 16 samples were from recently infected quarters,

TABLE III

SIGNIFICANCE OF THE FINDING OF STREPTOCOCCI IN INCUBATED MILK

Number of Instances	*Number of Quarters*	*Laboratory Evidence of Mastitis* *2 Weeks Preceding Test*	*At Time of Test*	*2 Weeks Following Test*	*Usual Type of Streptococci Isolated*
50	30	0	0	0	S
	3	0	0	+	A
	1	0	+	0	S
	7	0	+	+	A
	9	+	+	+	A

and 9 from quarters known to have been affected with chronic mastitis for some time. Cultures from these quarters were identified as *Streptococcus mastitidis* (Group A).

SUMMARY

The data presented confirm the opinion of others [5, 6, 7, 8] that the common cause of infectious chronic mastitis is a fairly well defined species or type of streptococcus, easily differentiated from *Streptococcus pyogenes* of human origin. A plan is described for differentiating *Streptococcus mastitidis* (Group A) from weakly pathogenic and saprophytic streptococci of bovine origin.

Microscopic examination of incubated milk samples was found to be the most effective of 6 methods used in detecting shedders of *Streptococcus mastitidis* (Group A). As saprophytic streptococci may occasionally be found in incubated samples from healthy quarters, the significance of the finding of streptococci in incubated samples from healthy quarters, in the absence of other evidence of mastitis, or during the first 2 and last 4 weeks of the lactation period, can be determined only by isolation and identification of the streptococcus found.

Maternal Mortality

. . . Unhappily, we are not in the same fortunate position with regard to the maternal death rate; that is to say, the deaths of mothers in connection with confinement. Confinement is a natural and normal process in which women are concerned in fulfilling the most important function of their lives, namely, providing the future generation. Childbirth is not a disease and should be free from death and danger; but in England and Wales, out of every 1,000 births, there are 4 deaths of mothers arising from pregnancy or confinement, and unfortunately this figure is not showing any decline. The figure 25 years ago was 3.87. It is appalling to think that 4 women in every 1,000 lose their lives in performing this natural function. The general death rate, as I have shown, has gone down by more than one-third since 1875; during the present century, the infant death rate has been reduced by nearly two-thirds; but the maternal rate has, in fact, shown an increase. This situation causes great concern to all interested in the well-being of women and small children.—James Fenton, M.D., Public Lecture to the South African Health Congress, *J. Roy. San. Inst.*, May, 1936, p. 644.

Diphtheria Immunization*

WILLIAM EDWARD BUNNEY, PH.D.
Associate Director, Bureau of Laboratories, Michigan Department of Health, Lansing, Mich.

THE most important question in diphtheria immunization today is whether or not alum precipitated toxoid is proving to be the satisfactory one-injection immunizing agent which preliminary work promised it would be. In answering this question a table has been made of the available figures on the use of alum precipitated toxoid (Table I). The results listed are from the use of single injections. They are analyzed to show the percentage immunized, the interval before the re-Schick, and the reactions from the alum precipitated toxoid. The results of McGinnes, *et al.*[3] and of Newitt[7] are especially interesting for the information they give on the durability of the immunity resulting from a single injection of alum precipitated toxoid. We must conclude from the results available that a single injection of alum precipitated toxoid is at least as potent in changing Schick positive children to the Schick negative state as the usual 2 or 3 injections of a non-precipitated toxoid with a potent preparation, and probably superior to the 3-injection toxin-antitoxin routine. Our ultimate approval of alum precipitated toxoid must now await upon proof that it is just as effective in conferring resistance to actual exposure to diphtheria.

The next important question is when should the Schick test be used? The consensus of opinion seems to be that if the immunizing is done in the most important age group, the preschool children, a pre-Schick is unnecessary. However, additional evidence has been presented during the last year by Greengard and Bernstein[8] which would tend to obligate the use of the Schick test in the infant under 9 months of age, because they find that the passive immunity received from the mother and responsible for the high percentage of Schick negative individuals at 6 months of age will interfere with active immunization with toxoid, leaving the Schick negative infant susceptible as soon as its passive immunity wears off. Whether or not this would apply as well to alum precipitated toxoid immunization is a question which only research can answer. As for the post-Schick, it would at first glance seem unnecessary to use it in the routine mass immunization of children after such a good immunizing agent as alum precipitated toxoid. Certainly from a public health standpoint the 5 or 10 per cent remaining unimmunized would have a negligible effect on the diphtheria incidence. We feel, however, that abandonment of the post-Schick test is ill advised, not only because of its value as a check on the immunizing agent and the technic, but even more important, because the result of the post-Schick test gives us the answer to that unavoidable question, "Why has

* Read at a Special Session on Diphtheria Immunization of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

my child, who has been injected, contracted diphtheria? "

As long as diphtheria is present in the country we will always have diphtheria in injected individuals not rendered Schick negative. The very fact that they resisted the immunizing treatment classifies them with those most likely to contract the disease. From the standpoint of the individual, as well as for the good repute of immunization practice, it would seem imperative to be able to say whether or not the immunizing treatment has been successful.

Further studies on other immunizing agents against diphtheria have appeared in the literature during the past year. Studies have been reported by Silberschmidt [9] on immunity in animals 16 days after the first inhalation of diphtheria toxoid. Leach, Jensen, and Póch [10] in studies on immunization with a single injection of purified toxoid plus aluminum hydroxide, found that all of 148 children studied gained in antitoxin following its use. Ramon and co-workers,[11] working on ointment immunization against diphtheria, showed that the skin must be broken by shaving or rubbing to obtain success. Bunney [12] has reported on intradermal injection with a toxoid-toxin mixture and found a doubling of the final antitoxin level from all immunizing procedures tried if as little as 0.5 L_f's of toxoid was contained in the pre-Schick test material. Although some of these may prove worthy of being used with or in place of alum precipitated toxoid, we do not believe available data warrant their recommendation for routine use

TABLE I

RESULTS OF IMMUNIZATION WITH ALUM-PRECIPITATED TOXOID

Age Group	*No. of Individuals*	*Pre-Schick Test*	*Interval Between Imm. Injection and Re-Schick*	*Per Cent Immunized*	*Reactions*	*Ref.*
Children	98	Pos.	8 weeks	94	No severe reactions	Wells, *et al.*[1]
School age	99	Pos.	2-6 months	94	Same as ordinary toxoid	Graham, *et al.*[2]
School age	86	Pos.	2-6 months	91	Same as ordinary toxoid	Graham, *et al.*[2]
444 preschool	613	Not done	2-4 months	97	Same as ordinary toxoid	Graham, *et al.*[2]
Children	1,765	Pos.	2 months	94	Same as ordinary toxoid	McGinnes, *et al.*[3]
Children	347	Pos.	1 year	95	Same as ordinary toxoid	McGinnes, *et al.*[3]
Preschool	264	Pos.	8 weeks	100	No moderate local, no general reactions	Shrifrin [4]
School and preschool	301	Pos.	8 weeks	94	2 moderate local, no general reactions	Shrifrin [4]
Adults avg. age 40 yrs.	196	Pos.	8 weeks	58	7% moderate local and general reactions	Shrifrin [4]
380 preschool, 208 school age	588	Pos.	63 days	98	Same as ordinary toxoid	Newitt [5]
4-19 years	53	Pos.	60 days	94	1 severe, 5 moderate general reactions	Keller & Leathers [6]
4-19 years	23	Pos.	42 days	100		
School and preschool	123	Pos.	1 year	89	Same as ordinary toxoid	Newitt [5]
Children	197	Pos.	2-3 months	100		Baker & Gill [7]
Children	1,400	Not done	2-3 months	99	0.05% abscesses	Baker & Gill [7]

at the present time. It might be well to point out here, however, that the work of Underwood,[13] and of Parish, Edin, and Wright[14] on the incidence of diphtheria caused by the virulent gravis strain of the diphtheria organism emphasizes the need of striving for the highest level of circulating antitoxin. They show that the usually accepted immunity level of antitoxin is not sufficient to protect against infection with this strain. In other words, in choosing immunizing procedures it may not be enough simply to choose those that convert a reasonable number of Schick positive children to the Schick negative state.

Other reports of interest in diphtheria immunization are those of Kuk Choun[15] on the relationship between the nutritive state of the animal organism and its response to active immunization. He found that animals on a diet rich in vitamins and receiving plenty of sunlight responded best to injections with a diphtheria antigen. The work of Tsen[16] on immunization against diphtheria and scarlet fever with the combined toxoids gives additional information on this important possibility. Further work needs to be done in both these fields, and their importance is obvious.

It might be pertinent in closing to point out some of the things which as yet we do not know about alum precipitated toxoid. We do not know the importance of the potency of the product—for instance, whether or not it makes any difference if the product is just good enough to pass the National Institute of Health requirements or is several times as potent. We know little about the stability of the immunity resulting from its use as compared with that resulting from the use of the unprecipitated toxoid given under the same conditions and at the same time. We have little available data as to the value of the product in the older age groups and can make no recommendations as to the dosage or interval to be used in these groups. We have little data on the stability of the product under ordinary conditions of storage and handling. We do not know if it will actively immunize 6 month old babies who have retained passive immunity from their mothers. Further carefully controlled studies are certainly needed on these phases of diphtheria immunization.

Determination and Estimation of Residual Chlorine*

A. E. GRIFFIN

Research Laboratory, Wallace & Tiernan Co., Inc., Newark, N. J.

RESIDUAL or free chlorine may be estimated either by the starch iodide method, by titration with thiosulphate, or colorimetrically with orthotolidine. Each method has its drawbacks, but of the 3, orthotolidine is the most sensitive, lends itself most readily to field use, and requires but 1 manipulation; namely, the addition of the indicator which produces a color varying in intensity with the quantity of chlorine present.

Thiosulphate cannot be used in water or sewage works practice because it is not sensitive to the residuals encountered in such work which usually run below 1.0 p.p.m. Starch iodide was used when chlorine was first introduced, but gradually gave way to orthotolidine after its standardization in 1913 by Ellms and Hauser[1] and its popular development by Wolman and Enslow[2] in 1919. Recent research indicates that a starch solution preserved with zinc chloride and used without acid at lowered temperatures may be very useful in distinguishing false residuals due to nitrites or manganese from true residuals.

The difficulty of preparing fresh standards consisting of known amounts of chlorine with each test prompted the preparation of permanent standards by Ellms and Hauser from potassium dichromate and copper sulphate. These standards were adopted by the American Public Health Association as the official standards for the determination of residual chlorine with orthotolidine. Certain discrepancies have been found and commented upon by Muer and Hale,[3] and by Adams and Buswell,[4] but the values given in the latest (1933) edition of *Standard Methods of Water and Sewage Analysis* of the A.P.H.A. are the values accepted by the profession.

Prior to the 1933 edition of *Standard Methods* the tube length for the matching of the developed color with the standard was not mentioned. This omission has caused considerable confusion among many workers, some of whom proceeded to match the colors in containers varying all the way from the original 300 mm. depth to 30 or 40 mm. When commercial comparator sets appeared on the market, complaints were received of their supposed inaccuracy, many of which were explained when it was found that the dichromate standard made for a 300 mm. depth had been compared through a 13 or 26 or 30 mm. depth with a liquid or glass standard which had been compensated for just this thing.

This mistake may be pardoned when one considers the large number of workers using the test who have had little, if any, technical training. It is only natural the average person in charge of a small water plant would assume

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

that if he cut down the standard and solution containing orthotolidine proportionally, he would get comparable results. This would be true of 2 chlorine solutions or 2 dichromate standards of the same strength, but it is not true of dichromate standards and the yellow color of orthotolidine in the presence of chlorine, because both colors are not of the same character: that is, they do not have the same absorption bands.[5]

This may be better understood when we remember that the reason we see green, red, etc., is because the object observed absorbs the colors other than those seen. Thus a red object absorbs the colors on the violet end of the spectrum, reflecting only the red. Likewise, blue objects absorb the red rays, reflecting only the blue.

In orthotolidine work solutions are compared and light is transmitted rather than reflected. This alters the picture of reflected light, for each molecule of dye stuff in solutions absorbs certain percentages of light, transmitting the rest. Thus the number of molecules in a solution governs the amount of light that passes. As an example, "if a 1″ depth of solution passes 70 per cent of the light, a 2″ will pass 70 per cent of 70 per cent, or 49 per cent. Likewise, a 1″ solution twice as strong will only transmit 49 per cent. In either case the light ray has twice the number of molecules in its path."[6]

FIGURE 1

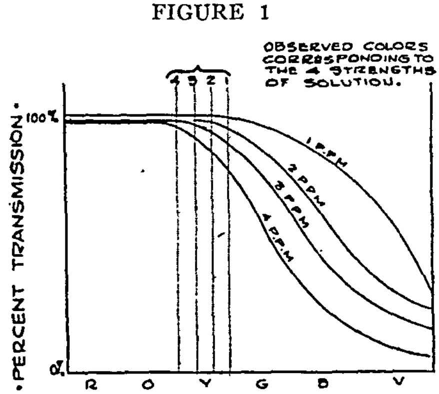

Figure 1 shows how the apparent color of various strengths of color of orthotolidine in the presence of varying amounts of chlorine shift when viewed through the same depth.

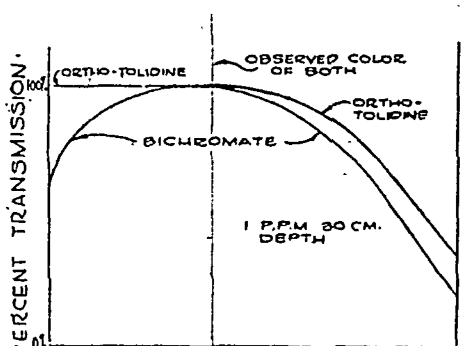
It is to be noted how the color shifts from the greenish yellow toward red as the concentration goes up.

The spectrophotometer reveals the following curves (Figure 2) for orthotolidine and for dichromate solutions at 30 cm. depth. It is to be noted they are quite similar but not identical, though the average color is the same. The copper sulphate in the permanent standard absorbs reds. Since there is no counterpart to this absorption in the orthotolidine color, this accounts for the difference.

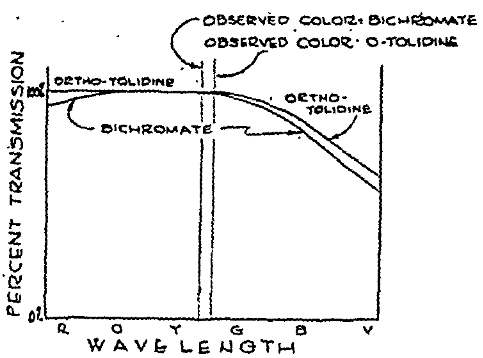
FIGURE 2



When these same solutions are compared at a 3 cm. depth, we get the effect portrayed in Figure 3.

Both solutions here appear lighter and more green than at the 30 cm. depth, but they no longer match. This is because the permanent standard has had an increase in transmission at the red end which pushes the observed color of this standard nearer this end. The orthotolidine color did not move in this direction because it already had 100 per cent transmission of color at that end of the spectrum.

FIGURE 3



While the curves shown in Figure 3 are not strictly accurate in all details they do portray why permanent standards must be compared with orthotolidine color at the 300 mm. depth unless corrections for these differences are made as they are in all commercial comparator sets.

Other difficulties encountered in the determination of residuals include the color of the tubes, the character of the light, cleanliness of the glassware, position of the tubes when comparing, and even the speed with which comparisons are made.

When the long tubes are used for comparison, the color of the glass may at times make a difference as great as 100 per cent, particularly in the lower values on the order of 0.01 p.p.m. to 0.20 p.p.m. The shades usually run from a light blue-green through a reddish brown to one that appears almost black. The light blues or greens appear to give the best results; the browns making matching difficult.

North daylight is best and even then when very accurate results are desired, days when the sun is alternately obscured should be avoided. A slightly overcast sky will give best results. Very consistent results may be secured by using an artificial daylight lamp and lens both day and night for routine work.

Position of the tube is very important. When close readings are desired, a higher and lower standard should be held on either side of the unknown and their position should be shifted frequently.

One should not look at the tubes for any length of time because the eye soon becomes fatigued in respect to color with the result that the shades may blend resulting in the hopeless confusion of the observer.

Reference to cleanliness of glassware may seem out of place, but I have seen false residuals produced by the solution of manganese from the pores of tubes by the HCl in the orthotolidine reagent.

Compensation for color or turbidity is of course impossible when the long tubes are used. This necessitates either going to one of the commercial sets or making special standards for use in bottles adjusted to a shorter observing depth.

There is little need to discuss here the effect of interfering substances, such as manganese, iron or nitrites on the test, since those subjects have been adequately gone into by R. D. Scott in the *Journal of the American Water Works Association,* May and September, 1934, and in the February, 1935, issue of *Water Works & Sewerage,* and by the writer in the *Journal of the American Water Works Association,* July, 1935.

It is perhaps sufficient to say that nitrites up to 0.1 p.p.m. cause errors of less than 0.01 p.p.m.[7, 17] but above 0.1 appreciable error will result while manganese in almost any quantity will give a false residual and should always be taken into account.[8, 9, 10] Iron in the ferric state, and especially when combined with organic material, may cause appreciable errors.[11, 12] Hulbert,[17, 18] Berliner,[19] Braidech,[20] and Hedgepeth,[21] have all noted the effect of nitrites in water on orthotolidine, but the effect of nitrites in sewage on the test has been given little attention.

Field experience indicates that they give little trouble here for false residuals have seldom been noted in sewage even where large amounts of nitrites were present.

In general, when the yellow color of orthotolidine is abnormally slow in developing or is off shade, one should suspect false residuals. Before this happens, of course, the water should be checked for presence or absence of interfering substances, and corrective measures taken.

Buswell and Boruff [13] in 1925 indicated that temperatures between 20° and 35° C. have little effect on the final readings, but that the readings will become progressively lower or progressively higher above and below these values and experiences in the field have checked these results. This leads to the conclusion that it might be well if all orthotolidine readings were made at a uniform temperature of about 20° C. When the temperature of a water falls below that point it can be readily raised without loss of chlorine by placing the sample in a warm water-bath for a few minutes. Some operators place the samples over radiators for a period which experience has taught them is sufficient to raise the temperature to the required point. It is quite probable that some of the taste difficulties encountered during the cold months may be due to chlorine in excess of the amount measured when the tests have been conducted on unwarmed water.

We are often asked for a method of determining between chlorine and chloramine residuals. To date, no entirely successful test has been evolved. Scott [14] mentions the use of the methyl red test which does give an indication of the presence or absence of chloramines, but this test is seldom wholely relied upon.

Attention has been drawn several times to the blue or bluish green color produced when the tube in which the yellow color of chlorinated orthotolidine has been produced is emptied and refilled with chlorinated water. This off-shade is probably due to the action of minute traces of orthotolidine which have stuck to the glass. Since the acidity of this adhering indicator is not strong enough to change the pH of the water appreciably, the blue or blue-green appears. It has been reported that a few exceedingly alkaline well buffered waters have produced these green or blue-green shades with the regulation amounts of orthotolidine. The effect is usually due, however, either to the addition of insufficient amounts of orthotolidine to 100 c.c. of water or the addition of the regulation amount of orthotolidine to a large volume of water. Either procedure might produce the same results.

Estimation of residuals in sewage is particularly difficult due both to turbidity and color. Turbidity may be easily compensated for by placing a second container of sewage having no orthotolidine ahead of the standard and a bottle of distilled water ahead of the unknown. But color is a different matter. Yellows or blues, for instance, may give greens of difficult matching qualities while the acid may discharge the color or at least weaken it to the point where a match can no longer be made with the standard. This difficulty may be minimized by adding 10 per cent HCl in equivalent quantities to the orthotolidine to the compensating bottle.

This method was used with considerable success at the Saw Mill River Treatment Plant of the Westchester Sanitary District where a nearby run works periodically discharged bright reds, greens, and browns into the sewer a few hundred feet ahead of the plant. Investigation proved that chlorine demands of the dyes were not as high as originally suspected but that the HCl

in the indicator altered the dyes to such a point that the residual could no longer be read.

Davis[15] of the New York State Department and Green[16] have noted that strong daylight will affect the sensitivity of orthotolidine to free chlorine. At Little Falls, N. J., the residual usually remains very consistent day after day. On occasions, however, they would fall very suddenly without warning and for no readily apparent reason. Careful checks demonstrated that the orthotolidine had suddenly lost its sensitivity to free chlorine. It is now standards practice at that plant to renew the test solutions every 6 weeks.

Orthotolidine itself may darken with age. This does not ordinarily alter its sensitivity but does result in a poor looking solution which has the psychological effect of throwing doubt on the test. This is caused by impurities in the salt. A sufficiently pure product to give a water clear solution is now commercially available so that recrystallization does not have to be resorted to.

It seems hardly necessary to speak of time of contact between addition of orthotolidine and time of reading, but I have had so many inquiries along this line that there must still be some question about it. Not more than 10 minutes for chlorine nor more than 20 minutes for chloramines is necessary for production of maximum color. Literally hundreds of samples were run at Bound Brook, N. J., a short time ago to settle this question. Readings were taken at 5 minute intervals and temperatures noted at each reading. This was not a laboratory experiment but was carried out on a natural river water under natural conditions as to weather, temperature, etc. The chlorine and ammonia rations were the only things changed. Very few of the chloramine samples required more than 20 minutes for full production of color, and the majority of the samples containing chlorine alone reached their maximum color intensity within 10 minutes. Practically all of the samples showed a fading of color at the end of 30 minutes.

Unless a water is severely polluted with sewage or industrial waste, the yellow color of chlorinated orthotolidine will usually last for at least 30 minutes unless exposed to direct sunlight. In sewage work, however, the color may flash up to a maximum within 5 minutes and then fade rapidly. Under such circumstances no time should be lost in making the determinations, and the maximum color produced in so far as we know will record the actual residual present. The reason for the flash of color and quick fading is probably due to the action of the chlorine on the organic matter which releases fresh reducing matter with the resultant decolorization of the orthotolidine.

The "Cure" of Leprosy

WE take no exception to the claims of the bacteriologists that when a patient recovers from a disease such as leprosy or tuberculosis it is impossible to prove that the causal organism has been eradicated or that there is no possibility of relapse. That relapses are frequent must be acknowledged by any physician who handles cases of leprosy. But we protest against the weakness of the clinicians who have allowed their bacteriologically-minded brethren to steal from them a perfectly good word, clothe it in the garments of a heretic, and then burn it at the stake.

We maintain that "cure" is a good old word, far older than the science of bacteriology, quite devoid of the meaning that is now sought to attach to it, and not in the least deserving the obloquy into which it has come. Webster, and such other dictionaries as we are able to consult, give us as the meaning of cure: to restore to health. Neither here nor in its cognate use—the cure of souls—is it for a moment suggested that no future fall from health, physical or spiritual, is guaranteed.

It is evident from every possible reference that what cure implies is a restoration to previous functional health, so that the victim is again able to take his place in society as a normal member thereof. Now our bacteriologically minded friends want to give an entirely new meaning to this word, and thanks to the weakness of their clinical brethren they are fast doing it. Cure is a good word, a kindly word, and it deserves no such harsh treatment.

. . . One sometimes wonders whether the fact that the pessimist sees so many fewer cures than the optimist is due not merely to a different, possibly more scientific, attitude of mind but also to the psychological effect that different types of minds have on patients. At any rate, we hereby lodge again the claim of the clinician to the restoration of the word "cure" to its proper significance, and invite our colleagues to find some other word implying that the patients are bacteriologically clean.—James L. Maxwell, Editorial, *Internat. J. Leprosy*, 3, 3:351–352 (July-Sept.), 1935.

Problems in Rural Registration*

R. N. WHITFIELD, M.D.

Director, Vital Statistics, State Board of Health, Jackson, Miss.

ACCORDING to the census of 1930, 44 per cent of the population of the United States is rural. In fact, 27 of the 48 states contain more than 50 per cent rural population. Therefore, it seems timely that a discussion should be had at this time concerning problems in rural registration especially since it is generally known that registration problems invariably center in the rural areas.

There may be some question about the fitness and capacity of the individual selected to prepare this particular paper, but I guarantee that his state contains all known problems in rural registration—and to a greater extent and in a wider variety than any other state in the Union. For nearly 12 years, I have wrestled with these problems and cudgeled my brain continually for methods of solution. We have managed to stay in the United States Registration Areas for Births and Deaths, which I consider a great feat under the circumstances.

What may be listed as the leading problems in rural registration?

First, and foremost, *illiteracy:*

1. In the general population
2. Among midwives, undertakers, rural doctors and rural registrars

Second, lack of medical attention, lack of funeral service due to poverty.

Third, inaccessibility—poor roads—scattered population.

Fourth, unreasonable laws and regulations.

ILLITERACY IN THE GENERAL POPULATION

The census of 1930 revealed that 4.3 per cent of our population is illiterate, and that the illiteracy percentage among the rural population is practically twice the figure prevailing in the urban sections. Unfortunately, we find most of the illiteracy banked in certain geographical divisions, namely, the South Atlantic, the East South Central, and the West South Central, all comprising 17 states.

Among these states, however, we find a comparative minimum of this condition in Delaware, Maryland, District of Columbia, West Virginia, and Oklahoma. On the other hand, a high percentage of illiteracy is recorded for 2 mountain states, New Mexico, and Arizona.

In the geographical divisions just mentioned, the census shows that the percentage of illiteracy among native born whites is 3.7, 5.0, and 2.6, respectively; whereas illiteracy among the Negroes, who constitute a large proportion of the population, is 19.7 per cent, 22.0 per cent, and 17.0 per cent. In the States of Arizona and New Mexico the high percentages of illiteracy are due to the Mexican and Indian components of their population. In Texas the census takers found a

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

million and a half Mexicans and Negroes—over 25 per cent of the total population of the state.

Mississippi is classed as 83.1 per cent rural, being exceeded only by North Dakota as a rural state. A fraction over 50 per cent of the population of Mississippi consists of Negroes, and 88 per cent of these are rural. The rural Negro in the United States was credited with 22.4 per cent illiteracy in 1930.

ILLITERACY AMONG SPECIAL CLASSES CONCERNED WITH REGISTRATION

1. *The Midwives*—In Mississippi there are nearly 3,000 so-called midwives, most of whom can neither read nor write. They attend 50 per cent of the births in the state; and of course a great majority of these births occur in the rural areas. If this state of affairs does not constitute a problem in rural registration, what does it constitute? Fifteen or 20 other states in the Union are faced with the same situation in lesser degrees.

2. *Undertakers*—The country undertaker usually develops more or less by accident. He is ordinarily a furniture or hardware dealer to begin with; then he puts in a small stock of coffins; finally, he buys a second-hand hearse and begins to bury the dead. He is afflicted with ruralitis anyway, and it is hard to inculcate in his mind the importance of registering deaths.

3. *Doctors*—The rural doctor as a rule means well, and many of them are well educated and up-to-date, but it is a fact that most of the old-timers and uneducated groups cling to the rural districts from necessity as well as choice. In the early days of registration they were principally the group that scoffed at birth registration as a piece of foolishness. Going further than this, I am convinced that few professors of obstetrics in the United States teach medical students the necessity and importance of birth registration.

4. *Local Registrars*—Our rural registrars can be blamed for many shortcomings. The majority of them are not systematic. They lose many birth and death records that have been entrusted to them for mailing to the central office. Many of my local registrars are downright ignorant, and I am confident that all of them in other states are not college graduates.

LACK OF MEDICAL ATTENTION—LACK OF FUNERAL SERVICE—DUE TO POVERTY

Possibly we are all aware of the surprise exhibited by physicians and health officials at one result of the recent depression.

When money became scarce back in 1931 and health appropriations were cut in half everywhere, we all put forth our big argument that people would die like sheep, and epidemics would stalk throughout the land. The truth of the matter is during the depression we had the lowest death rates ever reached.

But, lack of medical attention, however it may affect the death rate, does interfere severely with rural birth and death registration and with tabulations on causes of death. In certain sections, from 10 to 15 per cent of deaths occur without medical attention, and these do not include sudden deaths. Also, thousands upon thousands of births occur without medical attendants.

One of the ardent desires of my life is to see the day come when every man, woman, and child will be able to secure adequate medical, surgical, and hospital service when necessary. Lay literature and medical literature have teemed with articles on this absorbing theme for the past 3 years. Very few advocate State Medicine. I am not advocating State Medicine. In my state almost any humble Negro or

humble white man or any member of his family, can be buried decently, and how? Just by paying $1 a month for the whole family into the treasury of a burial association. The humble citizen saves money—the burial association makes money. My own family consisting of myself, wife, and numerous children, belong to a burial association run by a first-class undertaker, and I pay only $1 a month.

The president of an eastern medical university, in addressing a gathering of the American College of Surgeons, made the following suggestions for universal medical attention.

1. That those in easy circumstances should take care of their own medical and surgical service.

2. That the great middle class should pay associational dues to guarantee them proper protection.

3. That the indigent portions of the population should be treated at public expense.

I believe if you were to search the world over, you could not devise a more sensible scheme for rendering universal medical service, and it does not mean State Medicine.

There would result a marvelous improvement in rural birth and death statistics if there were medical attendants in all cases.

I have already more or less appraised the rural undertaker, but it is a fact that hundreds of deaths occur in certain sections of the United States wherein no undertaker whatever officiates. A large percentage of these deceased persons do not even enjoy the luxury of taking their final repose in manufactured coffins.

INACCESSIBILITY—POOR ROADS—SCATTERED POPULATION

Poor roads and inaccessibility of homes constitute major difficulties in successful registration in the rural areas. However, during the past 10 years rural roads have been vastly improved, even in Mississippi. Doctors think nothing of making calls 25 miles away, and undertakers travel over 100 miles in burying the dead.

The density of population in the states varies from 0.8 per square mile in Nevada to 644.3 in Rhode Island, and even to 7,852.7 in the District of Columbia, which of course means the City of Washington. Mississippi's density is 43.4 as compared to 41.3, the national average.

UNREASONABLE LAWS AND REGULATIONS

Most of our registration laws were passed in a different age from that in which we live today. In fact, anyone who is now as old as 40 has lived in two distinct eras of the world's history. Therefore, if our registration laws were founded on conditions existing 25 years ago, and have not been revised to fit modern circumstances, we are groping in the dark, particularly in rural sections.

It is not my purpose to criticise the laws and regulations that govern registration in any other state. However, I shall detail two radical departures made in Mississippi from the uniform registration law and will ask you to be the judges as to the wisdom of such changes.

1. Nearly 2 years ago we suspended the burial permit, except for deaths occurring in towns of 1,000 or more population and except for bodies shipped into other states.

2. During the present year, we are consolidating districts to the extent that in over half of our 82 counties we have only 1 registrar to the county.

Marked improvement in registration of births and deaths has been noted in our state as a result of these departures from the time-worn requirements that have been binding for nearly a quarter of a century. These changes have been made to fit modern conditions.

We feel that there would be just as much reason to require a physician to make out a birth certificate and file it and get a permit to attend a labor case as there is justification in requiring an undertaker to make out a death certificate; file it; and obtain a burial permit. Why should state boards of health take it upon themselves to give permits for burial of the dead? * If there is any suggestion of foul play, then the registrar refers the case to the coroner. We are not crime officials. Requiring a permit in rural areas in this day and time works an unnecessary hardship on the undertaker and the family. The family may be 20 miles from the undertaker. The doctor who treated the case may live 15 or 20 miles away, and the registrar may live 10 miles in another direction. The registrar or the doctor, or both, may not be at home when the undertaker calls. In such a case, the undertaker must travel nearly 75 miles just to file a completed certificate and obtain a permit.

We give our undertakers 5 days from date of death to file the death certificate. Our rural certificates are now in better shape and a greater percentage are being filed than heretofore.

As stated elsewhere, doctors now travel many miles in their practice, and it is nothing unusual for undertakers to transport the dead 100 miles or more; so we have become convinced that 1 registrar in a county simplifies registration for that political division, and lessens the work of the clerk or clerks in the central office who keep accounts with the registrars. The monthly reports of the county registrars in Mississippi have exceeded our expectations.

As proof of the fact that suspending the burial permit in Mississippi, except for deaths in towns of 1,000 or more people, has benefitted registration, our figures show that for the year 1934, the first year the permit was suspended, we had an increase of 1.4 per cent regular death certificates—that is, certificates filed on time. Also, we had a 9 per cent decrease in delayed filing of death certificates. This includes not only certificates filed by undertakers, but by families of deceased persons where no undertakers were employed. In fact, a large percentage of burials are done in Mississippi without the assistance of undertakers. The total number of death certificates filed in Mississippi during 1933, the last year that permits were in force, was 21,617; the total filed during 1934, the first year the burial permit was suspended, was 21,786.

Now that the leading obstacles to good registration in rural areas have been considered, you may very naturally expect some recommendations for their removal, or at least for their amelioration.

It is an undisputed fact that ignorance is the greatest handicap to progress; but I am glad to state that illiteracy is gradually dissipating, as shown by official figures. In all classes of our population the percentage reduced from 6.0 to 4.3 between 1920 and 1930. The percentage in the white race decreased from 4.0 to 2.7, and illiteracy in the Negro race came down from 22.9 to 16.3 per cent.

Furthermore, one must study and plan various and sundry schemes for appealing to the less educated. High sounding phrases and arguments on the value of statistics do not get very far with the illiterate. The greatest educational force we have had on the value

---

* Although the Council of the Vital Statistics Section expressed its disagreement with the view that the use of the burial certificate was unjustified, publication of this paper was approved by the Council for purposes of discussion.

In a supplementary letter, the author writes: "I realize that in a majority of states, it would not be best to suspend the burial certificate. It may not be the best policy in some of the southern states."

of registration is government compensation to so-called disabled veterans.

Another potent aid to registration is the necessity of proving the age of a child first entering school. While this is now required in many localities, each state should make such proof mandatory. A photostat of the birth certificate, or the Census Bureau Certificate, or other certificate of birth registration has great educational value, especially in the rural areas.

The matter of inaccessibility of rural homes is being solved by highway improvement and the general use of fast moving vehicles. In addition, we observe that this class of population is being reached through wider circulation of the daily press and through consolidation of public schools.

Our local registrar fee law was amended a few years ago so as to reward registrars for prompt reporting. Any registrar in Mississippi who does not live in a town of 5,000 or more population receives $.40 for each birth and death certificate filed on time, and only $.25 for each delayed certificate, whether the delay is the fault of the registrar or of some other person. This change in the fee law proved to be a wonderful stimulus for prompt registration in the rural areas.

I should not like to close without calling attention to the fact that every state registration department should have a field man. Unfortunately, I cannot say that I have one, but I have had one occasionally, and do know the great value of such an employee. There is no doubt but that a certain amount of prosecution is essential in this work. The field man is the proper individual to check the work and to prosecute where such a proceeding would obtain the best result.

Dr. J. G. FitzGerald to Make International Study of Methods of Teaching Preventive Medicine

DR. J. G. FitzGerald, Dean of the Faculty of Medicine, Director of the School of Hygiene and of the Connaught Laboratories, University of Toronto, has been invited by the Rockefeller Foundation to make a study of the methods at present employed in the teaching of Preventive Medicine to undergraduates in medical schools.

It is anticipated that the study will occupy a period of 1 year commencing September 15, 1936. Dr. Charles Edward Smith of the Stanford University Medical School, San Francisco, will assist in the undertaking. University Medical Schools in the United States and Canada, the British Isles, and in European countries will be visited in the course of the survey.

Dr. FitzGerald is to resign as Dean of the Faculty of Medicine, University of Toronto, June 30 next. He will be given leave of absence by the Governors of the university for the necessary period and will, it is expected, return to the University of Toronto in September, 1937, as Director of the School of Hygiene and of Connaught Laboratories.

Treatment of Undulant Fever*

I. FOREST HUDDLESON, D.V.M., H. W. JOHNSON, AND C. P. BATES
Michigan College, East Lansing, Mich.

THIS report is a summary of results obtained from the treatment of 100 cases of undulant fever with Brucellin. This disease has a tendency to become chronic following the acute stage, so that the chronic phase may be the more serious condition from a standpoint of the general health of the patient. It was therefore necessary to obtain data on the actual effectiveness of the therapeutic agent in bringing about complete recovery rather than to appraise it on the basis of a rapid termination of the acute stage. A large percentage of the cases were checked many months after cessation of the specific treatment.

Clinical diagnosis of undulant fever is not easy particularly in the chronic type and in children. The presence of specific agglutinins in the blood may furnish confirmatory evidence but cannot be relied upon, since the blood of many individuals shows Brucella agglutinins, sometimes in high titer, and a negative test does not always exclude this infection. A further aid is the intradermal test with Brucella allergin. This test does not distinguish between sensitization as the result of a previous infection and infection at the time the test is made. A new preparation which is a nucleoprotein suspensoid known as "Brucin" is now being studied. Further laboratory evidence may be obtained by measuring the Brucella opsono-cytophagic power of the blood. This test may also be used as an index of recovery from infection. Of the 100 cases studied the agglutinin titer was either negative or less than 1 to 50 in 33 patients of whom 22 were children under 11 years. In 85 cases, an attempt was made to obtain a blood culture. This was successful in 16 instances. Of the 16 cultures, 7 were *Br. abortus*, 5 were *Br. suis* and 4 were *Br. melitensis*.

It is difficult to estimate the value of any therapeutic agent for undulant fever. In many cases symptoms are of short duration; or if the disease is recognized early and the patient put to bed, uneventful recovery may follow in a few weeks. Recovery after specific treatment from an acute attack is not comparable to recovery from the distinctly different chronic disease. Only general data are presented for this series of cases.

In 70 cases the duration of symptoms before treatment with Brucellin was less than 121 days. Fifty-one, or 73 per cent, recovered within 22 days after the first injection, 18 or 26.1 per cent required more than 22 days for recovery, and 1 or 1.4 per cent failed to respond. In 30 cases the duration of symptoms before treatment was more than 121 days. In this group 17, or 56.6 per cent, recovered within 22 days after the first injection, 10, or 33.3 per cent, required more than 22 days for recovery, 3 failed to re-

* Abstract of a paper read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

spond, 2 of these cases terminating fatally.

If one excludes the 6 cases that failed to respond to treatment and the 2 that succumbed, it will be found that the average duration of illness per case before treatment was 159.3 days. The average duration of illness per case after treatment was begun was 18.3 days.

It is believed that an intradermal allergic test made with standardized allergin and a proved opsono-cytophagic test are indispensable aids to diagnosis and that the latter test is valuable for determining recovery.

Standardization and Application of Different Preparations of Diphtheria Toxoid*

OLGA R. POVITZKY, M.D., DR.P.H.

Bureau of Laboratories, Department of Health, New York, N. Y.

A VARIETY of media is used for the preparation of diphtheria toxin. In the Research Laboratory of the New York City Department of Health a powdered, purified extract of fresh veal and beef heart muscle, with 2 per cent proteose peptone, 0.5 per cent salt, 1 per cent sodium acetate, and 0.3 per cent maltose is used for making toxins for immunizing horses, unmodified toxoids, and toxoid flocculi extracts. A medium prepared by boiling fresh veal with 0.5 per cent glacial acetic acid in distilled water, with subsequent additions of proteose peptone, salt and maltose is considered more satisfactory for the preparation of toxoid alum precipitate since this precipitate is more homogeneous and smoother than that made from the first mentioned medium. Irrespective of the medium used, the toxins formed are alike in kind. When sufficiently potent they can be converted in toxoids by the addition of 0.4 to 0.5 per cent of a 37 per cent formaldehyde solution, followed by incubations at 38°–40° C. for 4 to 6 weeks.

Since the introduction of diphtheria toxoid for immunization, numerous attempts have been made to enhance its potency with the object of decreasing the dosage, using 1 or 2 in place of 3 doses, and eliminating both systemic and local reactions. The result is the toxoid alum precipitate. In older children and in adults severe reactions have been obtained, so that the New York City Department of Health uses this only for babies and children of preschool age. For school children crude toxoid in 2 doses is used. Reactions may be practically eliminated by the use of toxoid antitoxin flocculi extract, but many more flocculating units are required for antibody production than is true for the toxoid alum precipitate, probably due to the too rapid absorption of the extract. The toxoid antitoxin flocculi extract is used in adults only.

Unmodified toxoids, properly stored and preserved have an immunizing value proportional to the flocculating units. When phenol is used as a preservative, however, the antigenic value decreases

---

* Abstract of a paper read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

although the number of flocculating units remains the same. In general, the Ramon flocculation test is sufficient for initial titration of toxoids and is being used not only for titrating toxins, toxoids, and their derivatives, but also for crude diphtheria antitoxins. Discrepancies between this and the more laborious guinea pig method have been encountered in testing concentrated and purified toxoids and antitoxins, but some of these may be overcome by careful attention to the technic of the flocculation test.

Office of Public Health Education Established

THE U. S. Public Health Service has announced the establishment of the Office of Public Health Education. It is under the care of Assistant Surgeon General L. H. Thompson, Chief of the Division of Scientific Research. The purpose of this new Division is to carry out certain experimental studies in health education.

Its initial activities are: the training and instruction of young commissioned officers of the Service; special instruction for educators, health officers, and sanitarians from state health departments or from foreign countries; to make studies of educational methods employed in health agencies and other fields of education; studies in mass adult education through the use of the radio; making permanent records of available material; and the issuance of a bulletin to carry current health information primarily for the personnel of the Service.

The bulletin has been called "The Health Officer," the first issue of which appeared in May, 1936, and the second in June. It is intended that a monthly digest of current public health education be issued. The first two issues are pleasing and instructive. They contain a number of well written reviews of books.

We cannot help thinking that our government should be able to put out a better looking bulletin. The two issues received are of different sizes, one with a colored cover, and one in black and white. One is apparently mimeographed and the other multigraphed. At any rate, both of them are produced by some process apart from printing. Some of the reviews of books are signed and some of them have only initials. We believe that the value of a review depends largely on who wrote it.

We wish the new department all success, and the name of its Director assures us of its efficiency. The bulletin is also useful, but we hope that it will improve in its appearance.

EDITORIAL SECTION

IMMUNIZATION AGAINST DIPHTHERIA

EXCEPTING smallpox vaccination, perhaps our most important success in the prevention of disease by specific immunization has been with respect to diphtheria. No measure of this class, other than smallpox vaccination, has been more generally accepted or has resulted in a larger measure of success in the prevention of illness and death.

Immunization procedures against diphtheria have been singularly free from undesirable complications, when one takes into consideration the number of immunizations which have been done. This is particularly true of diphtheria toxoid, the agent now most extensively employed, whether given as the plain product or in the modified form usually spoken of as alum precipitated toxoid. The practical application of the latter in this country we owe largely to the genius of the late L. C. Havens, Director of the State Laboratory of Alabama. In the earlier stages of the use of this preparation a considerable number of local abscesses followed the injection of certain lots, but so far as known, no serious permanent injury has resulted. A very small proportion of abscesses continue to follow the use of certain batches, and research workers engaged in the testing of this preparation have not devised thus far a wholly satisfactory means for detecting by laboratory tests those batches likely to be followed by abscess formation, if indeed these undesirable local sequelae are actually due to any inherent property of certain preparations of alum precipitated toxoid.

There was a long interval between the establishment of the theoretical basis for immunization against diphtheria and the practical application of the procedure, but once the latter had been undertaken, thanks largely to the inspiring leadership of William H. Park, health officers and physicians rapidly extended its use, so that now a very considerable proportion of children in the period of greatest susceptibility to diphtheria have been and are being immunized.

The question as to which of the two preparations should be used, the plain toxoid or the alum precipitated toxoid, has been an open question for some years, sometimes bordering on the nature of a controversy; and it is feared that too often sight of the merits of the issue has been lost in efforts of proponents to popularize one or the other of the preparations. Generally speaking, European and Canadian workers have adhered to the use of the plain toxoid, being influenced doubtless by the high authority of Ramon. The plain toxoid has been largely replaced by the alum precipitated material in the United States, but nowhere else in the world has the latter made great headway.

Perhaps one of the reasons for the controversial situation arises from the fact that there is a lack of a generally accepted accurate method of standardization of the potency of any of the diphtheria prophylactics. While we have methods for evaluating their activity, they are by no means as exact as those for evaluating the potency of diphtheria antitoxin. Then, too, there is no uniformly accepted procedure as to the size and number of doses of the material used or as to the spacing between doses when more than one dose is given. In practical application the health officer would do well to bear in mind the particular age group in which susceptibility to diphtheria is greatest. Generally speaking, this is the group between the ages of 2 and 7. Perhaps it would be a good rule for ordinary public health practice, including public school work, to say that it is hardly profitable to immunize against diphtheria after 10 years of age.

Unquestionably the most important problem has been to secure immunization of the preschool child. Different health authorities have approached the problem in various ways. In one large city the follow-up based on birth records is so thorough that it is an exceptional child which does not have a diphtheria prophylactic before the age of 2 years. In many communities it is customary to leave the interests of the preschool child largely to the family physician, who it is feared in many cases has been rather negligent in failing to recommend this valuable life-saving procedure to his clientele.

Perhaps one of the most important problems is the degree and duration of the immunity produced by diphtheria prophylaxis. An ideal prophylactic would be one conferring an immunity in a large proportion of children lasting until natural immunity has developed. Few groups have been observed over a long enough time, and with sufficient care, to enable us to determine to what extent the various prophylactics have met this criterion. Obviously this is to a considerable extent the essential point of the whole program.

An outstanding variation in actual practice is with respect to the utilization of the Schick test for the detection of susceptibles and for the determination of the effectiveness of the immunization procedure. Although the Schick test is accepted as a practical means of measuring results in large groups of individuals, it is now recognized that it is not an infallible indication of the immunity status in the individual case. The preliminary Schick test has been abandoned generally in the younger age groups, but we see no justification for failing to do Schick testing after the injections have been given and a sufficient time allowed to elapse for the development of immunity. In some communities there has been a considerable degree of disappointment and uncertainty as to where the fault lay when diphtheria has attacked a fairly large number of children thought to be immune by reason of a series of inoculations, but not subjected to the Schick test after completion of the procedure.

THE LABORATORY SECTION

ORGANIZED in 1899 as "The Laboratory Section of Bacteriology and Chemistry" under the chairmanship of W. H. Welch, with Wyatt Johnson as the guiding genius, the Laboratory Section has been active throughout the 36 years of its existence, and never more so than at present. To many members of the Association, "Laboratory Section" and "Standard Methods" are essentially synonymous, and it is quite true that the major interim interests and activities have been centered about the formulation of procedures for use in public health laboratories. Little attempt has been made to interpret the results obtained by these laboratory methods because the Section has felt that so many factors other than laboratory data are involved that the formulation of "standards" would not only be difficult but unwise.

The oldest of the laboratory procedures is *Standard Methods for the Exemination of Water and Sewage,* now in its 8th edition. Chemical, microscopical, and bacteriological methods are included, for potable waters, sewages and effluents, streams, industrial wastes, and boiler waters. It is now a joint publication of our Association and the American Water Works Association, but a number of other national societies have coöperated, as well as many individuals. It is the hope of the Section that this manual will always represent the best American practice, and to this end a standing committee is continuously at work on the preparation of new editions. The methods are regarded as authoritative and intended for the guidance of properly equipped laboratory workers rather than for those inexperienced in chemistry or bacteriology. The book is not to be regarded as a substitute for adequate professional training.

Standard Methods of Milk Analysis has gone through 6 editions and the 7th is in preparation. These methods have the same status in the milk laboratory as the water methods have in the water laboratory. The Laboratory Section has been concerned chiefly with the bacteriological examination, since methods for chemical examination have been so well formulated by the Association of Official Agricultural Chemists which are included in our volume. It is proposed to extend the usefulness of *Standard Methods of Milk Analysis* to the more general field of dairy products.

At various times the Section has proposed other standard laboratory procedures, such as those for examination of disinfectants, air, or oysters. The formulation of methods for testing air has been transferred to the Industrial Hygiene Section, those relating to disinfectants have been withdrawn, but those for the examination of oysters and other shellfish are now being revised. In this, as in many reports submitted by the Laboratory Section, representatives of other Sections serve as members of the committee and are of great aid to those working, perhaps at times, too closely in the laboratory.

The success of "standard methods" in certain special interests of the public health laboratory has resulted in an extension of activities to include diagnostic methods ordinarily regarded as belonging to such laboratories. For 2 years a large committee has been at work on these. This is not really a new departure, since the Section has, for a number of years, discussed a series of able reports on the Wassermann technic and finally adopted a standard procedure. Reports have already been received dealing with such diagnostic methods as those for amebic dysentery, enteric fevers, undulant fever, meningitis, whooping cough, tuberculosis, and streptococcus infections. We hope to gather in a single volume

the most frequently used procedures and to publish them in such a form that new methods can be easily added and old ones brought up to date.

With other Sections of our Association and other organizations, the Laboratory Section has coöperated by appointing representatives familiar with the particular problems involved—for example: with Committees on Milk Pasteurization, Swimming Pools and Bathing Places, Waterways Pollution, Biological Stains, Bacteriological Examination of Foods.

With increasing and widening interests of the Section, it became evident that some coördinating group was desirable to systematize these activities. A Coördinating Committee was appointed to have general charge of all committees interested in the various laboratory procedures for which standardized methods are desirable, and to pass upon the procedures before their submission to the Section for approval. At present this committee consists of 5 members, of whom 1 is the Secretary of the Section; but flexibility in the set-up allows for expansion when needed. A recent proposal has been for a committee to consider methods employed in the care and use of laboratory animals. The various committees dealing with standard methods are appointed by the Coördinating Committee and consist of chairmen and referees on the various topics in which the committee is interested. This scheme has been operating satisfactorily for 2 years.

The various Section activities, combined with basic responsibility for the program of the Annual Meeting has thrown a burden on the office of the Secretary of the Section greater than was ever intended, and it is only a question of time before his duties will be too heavy to be handled by a busy man as a side issue to this regular occupation. Although the chairman and councilors have coöperated in planning the Annual Meeting, the bulk of the responsibility has fallen on the Secretary. The Laboratory Section can well be proud of the increasing number of papers submitted and the increased attendance during the past several years. The variety of subjects presented has been rather great, and ranging through the preparation and standardization of laboratory reagents and biological products, discussions of new laboratory procedures applicable to public health problems and the use of biological products in immunization, to reports of laboratory studies on the cause of diseases.

With no intention of over-emphasizing the importance of the laboratory, it must be stated that much of the work of a well organized health department is dependent fundamentally on its laboratory. The epidemiologist, the sanitary engineer, the school physician, the nurse, and the various clinics not only can utilize but need the laboratory, and it is the function of the Laboratory Section to see that efficient service is rendered.

PUBLIC HEALTH EDUCATION*

Where Is the Big Bad Wolf?—The big bad wolf, public opinion, who so recently has had press and radio cowed at the very thought of naming "social diseases" by their rightful names, seems to have vanished from most communities. Even as a flapping scarecrow to frighten off insistent health workers fewer and fewer editors and broadcasters will continue to claim protection against stupid readers and listeners.

Departmental Health Education Adviser — Department of Health, Seattle, Wash., has a Health Education Adviser. The bearer of the title, Dr. A. S. Baker, sent the following answer to a question as to the nature of his job:

> This office is quite new, having been in existence only about a year. The job is, briefly, to build up a public health library, starting with a room full of very old volumes, pamphlets, etc., answer correspondence from the public with reference to health matters, operate a mimeograph printing outfit, write up and broadcast radio talks or invite others to do so, take care of press information, check any health information matter before issue and generally correlate health education material issuing from the several divisions of the department.

What Has Been Accomplished?—A newspaper clipping is headed: Advertisers Hail Truth Movement. Celebrate 25th Anniversary of Campaign to Wipe Out Fraudulent Practices.

The accompanying note from the fellow worker who sent us the clipping reads:

> I would be glad to know how far the campaign for Truth in Advertising has really proved effective. Judging from the advertisements for quack medicines that I see in some papers, there has been no reduction in that kind of advertising although it is probable that it does more harm than any other form of advertising.

Taking daily newspapers as a whole there has been a tremendous gain over years gone by, but are there exceptions in your community?

How about the weekly newspapers? Foreign language and other class newspapers?

What have health workers done about it? What might they do about it, directly or indirectly?

An Idea for a Parade?—A city health officer wrote:

> There is to be a parade through the business part of the city with floats depicting the work of the various city departments. We wonder if you have any suggestions as to what subjects to show on a float about the Department of Health.

There have been successful parades for teaching health ideas or giving information, but we have heard of none in which the work of the health department was presented. The ideas we sent in answer to the letter were too feeble to reproduce here.

The time is past for helping the inquirer, but others may benefit from any experiences or suggestions which might be sent to the editor. There is likely to be an increasing number of historical and other public civic events in which the department or other health agency is expected to participate.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Taken for Granted in Illinois—As reported by B. K. Richardson, Chief of Public Health Instruction, Illinois Department of Health, Springfield:

> Out here on the prairies the "press" picks up on its own initiative, news items concerning venereal diseases and uses the word "syphilis" with no more hesitancy or hedging than it uses the word "tuberculosis" or "diphtheria."
>
> To illustrate: Recently, in a circular to local health officers, the State Department of Public Health commented on the greater reported incidence of syphilis this year as compared with last. Although not released as a news item, the Associated Press picked up the information and used it as a wire story.
>
> The leading down-state newspapers as well as the *St. Louis Post-Dispatch* carried the story. The *Alton Telegraph* and the *Cairo Citizen* based editorials on it. I heard a preacher in one of the leading Springfield churches refer to the story from his pulpit, using the word syphilis.
>
> Whenever the subject is pertinent to the discussion, the word syphilis is used with no hesitancy by members of the State Department of Public Health in radio broadcasts given over various Illinois stations. No objection whatever has ever been voiced by the studio managers.

Enclosed with the above was a mimeographed memorandum addressed "To Local Health Officers Only" which emphasized the current situation in the state. Also a photostat sheet reproduces 5 news clippings and one editorial in all of which syphilis was mentioned in headline or text.

Health Promotion Through Education—Under this title Dr. Iago Galdston addressed the West Virginia Health Conference. Dr. Galdston urged:

> We must reshift our emphasis from man's environment and its inimical elements, to man himself, to his habits, to his practices, to his personal hygiene—we must become teachers again, to teach man how to live.
>
> Health education in America is rooted in prohibitions and taboos, but we must abandon the technic of taboo and cultivate that of affirmation.

He sketched the integration of health education in the activities of the private medical practitioner, the voluntary health organization, and the public health organizations.

Address the author at 2 East 103d St., New York, N. Y., for copy of the reprint.

Why Memorize a Broadcast?—In June, 1936, *Journal,* under "The Martin Family Broadcasts" we copied the interesting and practical material prepared by Dr. and Mrs. Bauer for *Hygeia* concerning the series of episodes which will appear in that magazine.

We wish to question the suggestions for reproducing the episodes in the form of "make believe" broadcasts. Our suggestion is that the stage be not darkened, and that the lines be not memorized for presentation without script in hand. The process of broadcasting continues to fascinate many people. And the simulation of broadcasting carries over some of that interest. And the use of manuscript by the cast behind a real or imitation microphone does away with many problems of actors and acting. All depends upon the rendering of the lines, with attention to acting only as certain of the cast may need the dramatic action to enable them to give the lines effectively. Thus production is simplified, and the audience gets something of the studio atmosphere.

The statement from *Hygeia* that any medical or health organization "is granted permission to produce this material, provided no admission charge is made" might be amplified. On application to the authors, 535 North Dearborn St., Chicago, Ill., permission will be given for paid admission on a modest royalty basis. *We hope that some health groups will explore the possibility of giving one or more of the episodes with paid admissions.* Success in getting a paid audience for health education material would be a

real achievement, and a distinct advance in getting attention for health messages. Is it possible that we are giving away too much or, rather, that there are groups which would respond to projects which called for cash expenditure by the beneficiaries?

Get some Junior League or other group to put on a paid health broadcast?

Our Neighbors to the South—Always we have been delighted to show at the Annual Meeting of the American Public Health Association specimens of health education material from our members and readers in other countries.

This year, meeting in New Orleans, it would be especially fitting to have considerable representation of health education materials of all types from national and local health agencies in all the countries around the Gulf of Mexico and further south.

Posters for hanging, small items mounted in a portfolio or scrapbook, larger pamphlets and reports to place on a table—all could be used to advantage.

Later an address for sending such material direct to New Orleans will be supplied. In the meantime please write to the editor of this department of the *Journal* who is chairman of the health education headquarters.

We hope that brief annotations in English will be supplied because unhappily so few health workers in the United States and Canada can read any of the Latin American languages.

To Our Readers in All Lands—Our major group of readers, in Canada and the United States, have few opportunities for learning about the health education materials and methods of other countries. The editor of this department of the *Journal* is a volunteer not on the staff of the A.P.H.A., and is not in a position to write personally to our readers around the world to request their coöperation. So please take this as a formal request and a cordial invitation to send samples of your materials for educating the public, together with some paragraphs telling in simple manner the methods you follow.

An added favor, please! If the material comes from a non-English speaking country will you please send brief notes explaining the nature of the material and the nature of the health message it carries. And kindly get your brief manuscripts put into English for the sake of the poor editor who may find even greater difficulty in getting translations done.

Also please note what we say elsewhere to "Our Neighbors to the South" and accept it as an invitation to readers in any land. If you issue a periodical could you extend these invitations to your readers?

The Road of Life—Recently the Seattle Department of Health responded to one of those short notice requests (or demands) for a display in connection with a meeting. Dr. A. S. Baker reports what they did about it:

> We made a very good picture on cardboard with cut-out figures and water colors, using one of the members of our staff to do the work. This was hung on a wall over a table on which a supply of pamphlets was placed.
>
> The picture was of a hill upon which was shown life's road. Upon this road the cut-out figures were placed: a baby and, in order, a preschool child, a school child, an adolescent, a young adult, an adult at about 45 years, and an elderly person obviously in good health.
>
> Along the road was placed the "Fence of Health Protection" labeled opposite each figure in the order given above, "Proper Diet," "Diphtheria Protection by Toxoid," "Smallpox Protection by Vaccination," "Typhoid Protection by Inoculation," "Regular Physical Examinations," "Recreation," "Rest."

In the sky above the hill was printed " Protection of Health on the Road of Life."

This " Road of Life " guarded by the " Fence of Health Protection," skirted a precipice at the bottom of which was a swamp. For a very quickly gotten together thing, it seemed quite effective.

In the Philippines—Save for the illustrations *The Health Messenger* might well be issued as a popular health monthly by any state in the country. But the *Messenger* comes from the Bureau of Health, Department of Public Instruction, Manila, P. I. Miss Josefa Llanes-Escoda is editor and educational secretary of the bureau.

April, 1936, is a "National Hospital Day" number. One page pictures a hospital building, with smaller sketches labeled laboratory, dispensary, personnel, operating room, etc. Text: " These activities cost a great deal of money. Support your hospital." Elsewhere a simple sketch: a dollar in the center; curved lines from the dollar to hand made lettering to read: light 4¢, laundry 4¢, wages 13¢, salaries 31¢, etc. There are no dividing lines in the dollar for the different items. The point is made by the larger numerals for the items in cents.

Miss Llanes-Escoda would appreciate receiving samples of health education material.

A Y.W.C.A. Health Program—What the Public Health Committee of the Central Branch, Y.W.C.A., Chicago, Ill., is trying to do is outlined in *Womans Press,* 600 Lexington Ave., New York, N. Y. June, 1936. *20 cents.*

The committee is " bearing in mind the necessity of concentrating on few topics and reaching more of the membership."

A " study of physical defects and conditions prevalent among women in touch with the Health Education Department " provided the subject matter for the educational program.

Health Education in May, 1936, Journal—For the possible convenience of students and writers, as well as health agency staff members, we review here references to be found in the May, 1936, issue of the *Journal* which have a bearing on health education or which may have special value to workers in health education.

In " Child Health and the Elementary School," by Phair, note the situation of " the average child " as stated in last paragraph, page 455, and the whole of page 456.

In " Comparative Value of State Districts and County Districts as the Basis of Local Health Organization," by Godfrey, note two paragraphs on " propaganda " on page 466.

In " Integrating Mental Hygiene," by Patry, note the last paragraph on page 478 which states the necessity for combined professional and community efforts in the successful development of mental health.

On page 479 is announced the request of State and Provincial Health Authorities that the Children's Bureau assume responsibility for the annual " May Day–Child Health Day " which for so many years has been sponsored by the American Child Health Association.

See the symposium on " Consumer Demand for Vital Statistics," by Round, Doull, Eliot, Bolduan, and Thompson, and Thompson (pages 489–505).

Under " Health Code on National Basis " (page 511) the 5th heading is: Education and publicity . . .

Under " Relationship of the Public Health Nurse to the Part-time Local Health Officer in Communicable Disease Work," by Arnstein, this question is raised:

What responsibility has she in reporting

cases, in selection of cases to be visited in education of the community?

See announcement of *Educational Abstracts* (page 527) which includes a section on "Health and Physical Education."

"New Orleans, The Convention City" (pages 540–545) may help some readers to decide not to miss the October meeting in that city.

Another group of members of the Public Health Education Section is announced on page 549.

"Summer School Courses in Public Health" are listed on pages 552–555.

"Conferences and Dates" are announced on pages 559–560, and "Meetings of Affiliated Societies and A.P.H.A. Branches" on page xii.

Numerous reprints from the *Journal* are listed on page xii.

Health Education in June, 1936, Journal—References of interest to health educators are noted below.

"For an Amended S. 5" (page 585), quoted from *Printer's Ink,* states the case of a group of organizations on the current "Copeland Bill."

"Set-Up and Budget for Public Health Education," by Hiscock (pages 593–596), was one of the important papers presented at Milwaukee.

"Integration of the School Health Program with Community Health Education," by Blanchard (pages 625–628), also comes from the Milwaukee program.

Reports on educational qualifications of engineers and of sanitarians (pages 629–633) are contributions to the study of professional preparation in which health education should have a continuing share.

Most important in this issue of the *Journal* is the editorial on "Work for the Editor" (pages 636–637). Addressed to those who will write papers for the New Orleans meeting, much of the editorial has a bearing on the writing of popular health education material.

"In Books and Reports" see "American Chamber of Horrors" (page 650).

See "For All to Read" under "A Selected Public Health Bibliography With Annotations" (page 653).

"Health Conservation Contests for 1935" are reported on pages 655–656.

Another fine list of new members of the Public Health Education Section is given on page 658.

"Scientific Exhibits in New Orleans" (page 659) is an important announcement.

September 1 is stated as the closing date for acceptance of applications for Fellowship to be acted upon at New Orleans (page 659). The Public Health Education Council would be glad to receive Fellowship applications from a number of the Section's members.

HONORABLE MENTION

To Departamento Nacional de Higiene, Republic of Colombia, Bogota: for an annual report with a 4 page index.

BOOKS AND REPORTS

Why Keep Them Alive?—*By Paul De Kruif, in collaboration with Rhea De Kruif. New York: Harcourt, Brace,* 1936. 293 pp. Price, $3.00.

Here at last is a popular glorification of public health activities. In the course of this fervent treatise, De Kruif devotes much space to the child welfare and antituberculosis work conducted in Detroit under the direction of Health Commissioner Henry F. Vaughan and his able corps of assistants. Other eminent sanitarians, including Drs. W. H. Park, L. I. Dublin, S. McC. Hamill, B. Marquette, H. C. Sherman, and Haven Emerson, also come in for mention in various parts of the book.

The 10 chapters, written in the author's usual ebullient style, but with somewhat more inspiration than usual, present the thesis that many children in this country are underprivileged, malnourished, poverty-stricken, and generally forgotten; that they are worth saving; and that skillful efforts now being undertaken by a group of competent and devoted health workers should be supported and enlarged.

In addition to the chapters on tuberculosis and on child hygiene generally, there is excellent material on nutrition, emphasizing the "rediscovery of milk's amazing array of virtues," and there is a most interesting chapter on the Dionne quintuplets.

This well printed book by a popular writer turned sociologist should be of interest not only to all members of the public health profession, but should yield many useful facts which health workers can employ to advantage in their endeavors to educate an apathetic public, and should aid in awakening the people themselves to a realization of some of the more urgent public health problems. JAMES A. TOBEY

Great Doctors of the Nineteenth Century—*By Sir William Hale-White, M.D. London: Edward Arnold and Co.,* 1935. 325 pp. Price, 15s net ($5.00).

This is not only a delightful book to read, but it tells us of great men with whose history all interested in medicine should be familiar. Most of the great doctors selected are probably well known to the average medical graduate in this country, though it must be confessed that in spite of the influence of Osler, sufficient emphasis is not laid on medical history in our medical colleges. Some names, like those of Jenner, Cooper, Bright, Simpson, Stokes, Manson, Lister, and Ross will be recognized immediately. Some, like Hughlings Jackson, will be known to neurologists. Sir John Simon is probably comparatively little known except to sanitarians. He was Lecturer on Pathology at, and on the surgical staff of, St. Thomas's, but acquired fame as a pioneer in sanitary science.

The author gives a sketch of each man considered before pointing out the work which made him famous.

We do not like to quote the hackneyed phrase, "Lives of great men all remind us," etc., yet there is one feature so outstanding in this book that we cannot refrain from doing so. Many of these great men came from large families, poor in this world's goods, had a severe struggle to obtain

their education and to get started in the profession in which they made such brilliant records. In this there surely is a lesson for many of the young men of the present day in America, who, owing to economic conditions as well as to competition, find it hard to get a start. There are notable instances, rare today—at least in this country—of a freedom from jealousy and an overwhelming desire to see results accomplished rather than to gain credit. This is brought out particularly in the history of Sir Samuel Wilks, who is said to have preferred that Hodgkins be known rather than himself.

In a book of such general excellence, it is hard to select one chapter over another. For readers of this *Journal*, however, we believe that the histories of Edward Jenner, Sir John Simon, Sir Patrick Manson, and Sir Ronald Ross will be of particular interest, though while saying this, it is recognized that the vast majority of those who take up this book will read every chapter, and we are not blind to the fact that the work of Lord Lister in advocating and perfecting antiseptic surgery, for example, has had an enormous influence in promoting the acceptance of the great truths taught by Pasteur which underlie public health of today.

In the days in which these men lived, formal lectures were the rule. Bedside teaching was conducted in a very different manner from that of the present. No one better fitted than the author to write on these great doctors could have been chosen. Many of the men of whom he writes were on the staff of Guy's or St. Thomas's Hospital, to the former of which the author is the consulting physician, and of which he is a distinguished alumnus. He was probably taught by some of the men of whom he writes, or by their former students.

The book is admirably printed and made up. There are very few mistakes, and only one liable to lead to misunderstanding. On page 267, Lister is compared to himself instead of to Liston. The whole book is delightful reading, and we trust that it will increase the love for medical history for which Osler worked so many years and in which he has left in this country some distinguished successors.

MAZŸCK P. RAVENEL

The Art of Leadership—*By Ordway Tead. New York: McGraw-Hill,* 1935. 308 pp. Price, $2.50.

The most successful health officer must be a leader—of his staff, of public health thought in his community and of professional and lay groups in his community with respect to their public health activities. This phase of his activities is not an important part of his training either in schools of public health or schools which prepare for this training. He must depend therefore for the present on such books as this for guidance.

The author performs a useful service in analyzing the art of leadership and pointing out its superiority over bossing as a method of permanent achievement. There is a chapter on conference leadership which should be read by everyone who has occasion to preside over any group meeting of three or more people. That a high degree of physical health is a valuable asset in leadership is implicit in many of the author's statements.

HOMER N. CALVER

Health and Human Progress—*By René Sand. New York: Macmillan.* 278 pp. Price, $3.00.

This is a learned, interesting and stimulating essay on social progress, past, present and future. The author ranges widely in space and time and the title of the book does not adequately describe its scope. His thesis is that medicine—" sociological medicine "—

must save the race. He does not convincingly demonstrate why he elects this particular branch of learning to achieve this noble end, nor why he chooses this designation for the curriculum of improvement. He says,

> Sociological medicine demands the provision, by *collective measures* of favourable labour conditions, good housing, decent wages, generalized insurance, sanitary, technical and educational services, to be completed by the *individualized action* of medical and social case work.

Most of this is "good medicine" but it is better described as social planning or social hygiene, as that term is used in the author's country.

The necessary, important and increasing part which medicine must play in the further social development of the race is discussed thoroughly and intelligently with a background of world-wide knowledge of national medical and social situations. These glimpses of conditions and achievements in many countries alone recommend the book as required reading for students in this field. Much of it will interest the general reader but it is essentially a textbook, and includes a most excellent and lengthy bibliography. The index is not adequate for the wealth of material treated.

There are few men in the world who have had such opportunity for the study of social conditions in all parts of the world as the author. Nevertheless, he tends to confuse medicine in its relation to social progress with the relation of social progress to public health. His preoccupation with the problems of medical relief for the sick poor and sickness insurance tends to crowd out consideration of such fundamental programs as those for water purification, insect eradication, and milk pasteurization, which are so essentially social in their concept and execution, with tremendous influence on the *mass* prevention of disease and therefore proper for prime treatment in a book on health and human progress. Though much space is given to the problems of medical economics in the United States and elsewhere, the rôle of epidemiology in the prevention of crowd disease is not discussed. Snow's classic studies on cholera are not even mentioned. HOMER N. CALVER

Annual Report of the Surgeon General of the Public Health Service of the United States for the Fiscal Year 1935—*Washington: U. S. Government Printing Office,* 1935. 158 pp. Price, $.75.

This report is always of interest. Unfortunately, it is generally many months late. Although it is dated October 15, 1935, it did not come to hand until January, 1936. It concerns the state of public health for the calendar year of 1934.

The death rate for the year was 10.9 per 1,000—0.4 per 1,000 or 3.8 per cent higher than for 1933. It is, however, lower than for any recorded rate before 1932. The birth rate has increased to 17.1 per 1,000 against 16.6 for 1933. This means that there were 93,975 more births for 1934 than for 1933, an increase of 3 per cent. The infant mortality rate is higher than for 1933. In 1934, there were 59.9 deaths under 1 year per 1,000 live births, against 58.2 for 1933. Again, the rate is lower than for any year prior to 1932.

The tuberculosis death rate for 1934 was 56.2 per 100,000, the lowest ever recorded by the Public Health Service. Typhoid fever and diphtheria had exactly the same rate, 3.3 per 100,000.

The outbreak of poliomyelitis in California in 1934 has already been noted. For 1934, there were 6.4 cases of the disease per 100,000 population reported. Late in the fiscal year of 1935, outbreaks occurred in North Carolina and Virginia, which are de-

scribed in full in the *American Journal of Public Health* for February, 1936. In July, 1934, dengue appeared in Florida and spread to Georgia and Alabama, there being 2,005 cases in Florida, 1,962 in Georgia, and 1,072 in Alabama. The actual number of cases must have been tremendously greater, as dengue is very imperfectly reported.

During the year 1934, 775,000 cases of measles were reported, nearly double the number reported in 1933.

One fatal case of plague was reported in Lake County, Ore., and one non-fatal case in Tulare County, Calif. There were found during that year 197 plague-infected ground squirrels and one plague-infected rat in California.

One of the blots on our record is smallpox, 5,371 cases being reported. This, however, is the smallest number since records have been kept, and 10 states have had no cases.

Our maritime quarantine has been very effective. Quarantine officers of the Public Health Service inspected 15,262 vessels and 1,924,556 persons; 12,482 vessels, 544,255 passengers, and 981,361 seamen were inspected upon arrival at continental United States ports. Of a total of 4,081 arriving airplanes, carrying 34,135 persons, only 2,636 airplanes, carrying 30,249 persons, of whom 1,991 were aliens, were accorded the medical inspections required by law; the remaining airplanes arrived at airports of entry at which medical officers of the Public Health Service are not available for duty.

The certification of water supplies for use on railroads, busses, vessels, and airplanes was continued with the assistance of state health agencies, 95 per cent of the listed supplies being inspected and certified; 58 supplies were prohibited, and 401 provisionally certified.

The study of venereal diseases has been carried on and is not very encouraging. During the year, 254,551 new cases of syphilis and 161,810 new cases of gonorrhea were reported. It is estimated that there are 518,000 new cases of syphilis and 1,555,000 of gonorrhea each year.

The report is an interesting review of health conditions in the United States.

MAZŸCK P. RAVENEL

Mouth Hygiene for School Age Children, Rendered by Several Coöperating Agencies in Cleveland During 1935—*By Harris R. C. Wilson, D.D.S. Cleveland, Ohio: Cleveland Board of Education (privately printed),* 1936. 79 pp.

While this is mainly a report of dental services rendered in the Cleveland schools last year, it might well be used as a textbook for public dental health work. No matter how much one may distrust projects aimed at furnishing the greatest amount of essential dentistry at the lowest cost, the recommendations of a man who has supervised the dental care of a half million school children must be given respectful attention.

Dr. Wilson's plan concedes the impossibility of administering complete dental care to all people, and limits its efforts to fillings in vital teeth only, for children. The service is entirely in professional hands. The cost to the patients is within their ability to pay. The compensation of the dentist is reasonable. The value of such a service to a community is inestimable.

It is impossible for a dentist to read this report without being impressed by the soundness of the writer's observations.

C. F. ELZEA

Introduction to Human Parasitology—*By Asa C. Chandler, Ph.D. (5th ed.) New York: Wiley,* 1936. 661 pp. Price, $5.00.

The announcement of a new edition

of this standard book will be greeted by all students of the subject of which it treats.

The 4th edition was rewritten and rearranged owing to the great advances which had been made in the field of parasitology since the third edition. Since that time the pace has been kept up and again the author has found it necessary to rewrite the book. Extensive changes have been made in the chapters or sections dealing with the spirochetes, amebae, malaria, ricketsias, flukes, Strongyloides, filariae and myiasis. In addition the author states that the prolific work of parasitologists of the past 6 years has made it necessary or desirable to make some change on practically every page. The author also points out that it is necessary to revise his statement, made in the 4th edition, that there was no entirely satisfactory modern textbook on medical entomology, and now gives generous credit to the several which are available.

A book which has reached its 5th edition and which has for so many years been regarded as a standard is certainly above the criticism of the average reviewer. This one will doubtless continue to hold the position it has for so long occupied as a standard.

The printing and make-up are good. There are abundant illustrations which are really illustrative and informative. MAZŸCK P. RAVENEL

The Bacteriological Grading of Milk—*By G. S. Wilson, M.D. London: Medical Research Council, 1935. Spec. Rep. Series, No. 206.* 392 pp. Price, 7s. 6d. net.

Modern methods for the bacteriological grading of milk to indicate cleanliness and keeping qualities may have to be drastically revised as a result of the facts presented in this somewhat formidable document. As a consequence of investigations extending over 3 years, Professor Wilson and his assistants at the London School of Hygiene and Tropical Medicine conclude that most of the present bacteriological methods used for milk are inaccurate and unsuitable. Thus, they condemn the plate count as guilty of very large experimental errors, and they state that the coliform count gives fictitious and misleading results, except possibly for freshly pasteurized milk. Similarly, the sediment test, the leucocyte count, the H-ion concentration, the titrable acidity, the bromthymol test, the keeping quality test, and the laboratory pasteurization test have all been carefully examined and found defective for routine purposes, although occasionally valuable for special uses.

The Breed smear method receives praise as a practical method for rapid examination of milk, and is declared to deserve greater attention than it now receives, at least in Great Britain. As a replacement for all methods now employed, however, the authors suggest a modified methylene blue reduction test, the modification consisting essentially of half hourly inversion of the tubes to keep the fat and microörganisms in a more or less homogenous dispersion. This test is advocated as a simple, inexpensive procedure, having a small experimental error, and suitable for use by relatively unskilled workers who are dealing with large numbers of samples.

Milk sanitarians and laboratory workers will find this book interesting, valuable, and provocative, especially since the experimental work has been nicely, meticulously, and very capably performed. JAMES A. TOBEY

Convalescent Care in Great Britain—*By Elizabeth Greene Gardiner, Assistant Professor and Supervisor of Medical Social Work, University of Minnesota. Chicago: Chicago Uni-*

versity Press, 1935. 163 pp. Price, $1.50.

This is a book which will interest those called upon to make hospital surveys or studies bearing upon the organized care of the sick.

The convalescent, like the chronic case, frequently has little provision made for him, particularly in the smaller centers. Although general hospitals in 1935 had an average bed occupancy of only 64.3 * per cent, the occupancy is not equally distributed for the whole year, so that at times discharges from hospitals have to be made when the patient still needs convalescent, if not regular, hospital care.

* *J.A.M.A.,* Mar. 7, 1936.

Moreover, where convalescent facilities exist, a patient who needs only convalescent care can usually be provided for at much less cost than in a regular hospital. Professor Gardiner has shown how Great Britain compares with the United States in the provision made for this type of patient. Convalescent care in Britain is provided for a larger proportion of hospital cases, the institutions providing the care are, on an average, larger, and on the whole greater pains are taken to see that the institution by location, equipment, and service meets the particular needs of the convalescent case.

A splendid bibliography forms part of the survey. JAMES WALLACE

BOOKS RECEIVED

SOLVING PERSONAL PROBLEMS: A Counseling Manual. By Harrison Sacket Elliott and Grace Loucks Elliott. New York: Holt, 1936. 321 pp. Price, $2.00.

SECURITY AGAINST SICKNESS: A Study of Health Insurance. By I. S. Falk. New York: Doubleday, Doran, 1936. 423 pp. Price, $4.00.

THE BABY AND GROWING CHILD: Feeding and Health Care for Physicians, Mothers and Nurses. By Louis Fischer, M.D. New York: Funk & Wagnalls, 1936. 260 pp., ill. Price, $1.50.

SYPHILIS AND ITS TREATMENT. By William A. Hinton, M.D. (Macmillan Medical Monographs, George R. Minot, M.D., S.D., Editorial Advisor.) New York: Macmillan, 1936. 321 pp. Price, $3.50.

A SURVEY OF PUBLIC HEALTH ACTIVITIES IN HONOLULU, HAWAII, INCLUDING OFFICIAL AND VOLUNTARY AGENCIES. By Ira V. Hiscock, M.A., C.P.H. Chamber of Commerce of Honolulu, Hawaii, 1936. 149 pp., ill.

THE DIABETIC LIFE: Its Control by Diet and Insulin. By R. D. Lawrence, M.A., M.D., F.R.C.P. 9th ed. (London.) Philadelphia: Blakiston's, 1936. 231 pp., 15 ill. Price, $3.00.

FOOD, HEALTH AND INCOME. By John Boyd Orr. New York: Macmillan, 1936. 71 pp., ill. Price, $1.00.

MOUTH HYGIENE FOR SCHOOL AGE CHILDREN, Rendered by Several Coöperating Agencies in Cleveland During 1935. By Harris R. C. Wilson, D.D.S. Privately printed. Cleveland, Ohio: Cleveland Board of Education, 1936. 79 pp.

SOCIAL WORK AS A PROFESSION. By Esther Lucile Brown. 2d ed. New York: Russell Sage Foundation, 1936. 120 pp.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Dietary Fads and Facts—Every health worker who has the least responsibility for influencing public attitudes or ideas should read this excellent article. It is to be hoped that it will be reprinted and made widely available as have earlier health contributions in this remarkable magazine.

ANON. The Wonders of Diet. Fortune. 13, 5:86 (May), 1936.

Preschool Hygiene—A recital of the steps by which Milwaukee progressed from a summer round-up to a year round health program for preschool children.

BRUMBAUGH, E. V. Completing the Child Health Program. Pub. Health Nurs. 28, 5:286 (May), 1936.

Barometric Infant Deaths—Infant mortality rates are a sensitive index of municipal public health *if* the number of births exceeds 500 per year. Less than that number causes too wide a fluctuation. Unusual social and economic conditions may invalidate the index in larger communities.

DERRYBERRY, M., and VAN BUSKIRK, E. The Significance of Infant Mortality Rates. Pub. Health Rep. 51, 18:545 (May 1), 1936.

Proof of the Value of Diphtheria Prophylaxis—Suggesting that the reduction in diphtheria morbidity rates may be due to other factors than our praiseworthy immunization campaigns, the authors call for more studies which will include pre-immunization Schick tests.

LUCIA, E. L., and WELKE, H. F. Trends in the Prevalence of Diphtheria. J. Infect. Dis. 58, 3:306 (May–June), 1936.

Measles Prophylaxis—Reporting the successful use on a county-wide basis of immune globulin in the prevention of measles.

MCGAVRAN, E. G. County-Wide Use of Immune Globulin in the Modification and Prevention of Measles. J.A.M.A. 106, 21: 1781 (May 23), 1936.

Dependent but Well Nourished—Praising the work of relief agencies in preventing malnutrition in school children and adults, the author reviews divers reports on the nutritional status of the American people.

MCLESTER, J. S. Influence of the Depression on the Nutrition of the American People. J.A.M.A. 106, 22:1866 (May 30), 1936.

Hot Weather Hints—Excellent radio advice, but the words are polysyllabic.

OLESEN, R. Care of the Health in Hot Weather. Sci. Month. May, 1936, p. 457.

More Evidence Against Raw Milk—Ice cream containing toxins elaborated by staphylococci originally from a mastitis and transmitted through raw milk was responsible for a food poisoning outbreak.

SHAUGHNESSY, H. J., and GRUBB, T. C. Staphylococcus Food Poisoning. J. Infect. Dis. 58, 3:318 (May–June), 1936.

New Objectives in Public Health—Not sanitation, nor epidemiology, not even the conquest of chronic diseases, but the promotion of health will be the keystone of the administrative program of the future.

WINSLOW, C.-E. A. When Is Public Health? Survey Graphic. June, 1936.

ASSOCIATION NEWS

NEW ORLEANS PROGRAM

THE second meeting of the Program Committee was held in New York on June 5 with representatives of each Section in attendance.

A preliminary scientific program of 2 General Sessions, 3 Special Sessions, 10 Joint Sessions, and 21 individual Section Sessions was approved. A number of special breakfast, luncheon, and dinner meetings was also approved.

The programs will be published in full in the September *Journal.*

Leafing through the tentative outlines submitted to date, a number of important subjects and speakers stand out prominently. Dr. Thomas Parran presents the address of the incoming President. Dr. Henry E. Sigerist, eminent medical historian, is the Banquet speaker. Dr. Thorvald Madsen, Director, State Serum Institute, Copenhagen, Denmark, speaks at the luncheon meeting on Professional Education. The report of the Diphtheria Immunization Committee is presented at another luncheon meeting.

Mental Hygiene is the subject of a Special Session; Mosquito-Borne Diseases another; and Advances in Public Health a third.

The Southern Branch of the Association is sponsoring a dinner session, and the Health Officers are planning another which is entirely a social affair.

There are symposia on syphilis, on food poisoning, on the public health engineer in industrial hygiene and sanitation, on school health education, on eating utensil sanitation, on promotion of birth and death registrations and their interpretation, on milk and dairy products, on enteric fevers, on intestinal parasites, on health publicity and news, on infant and maternal mortality, on municipal engineering problems and activities, and many more.

The papers in the miscellaneous sessions are equally timely and important. Speakers in every case have been selected from among those best equipped to present their material.

The New Orleans program will add to the reputation the Association has been building for itself on the score of distinguished and authoritative Annual Meeting presentations.

Full information about the post-convention tour through Florida to Cuba will be mailed to the membership in the near future.

The Program Committee approved the plans for reception and entertainment submitted by Dr. W. A. McPhaul, State Health Officer of Florida, and Dr. Domingo Ramos, Director of Sanitation, Havana, Cuba.

CLOSING DATE FOR FELLOWSHIP APPLICATIONS

THE Committee on Fellowship and Membership wishes to announce that September 1 is the closing date for accepting Fellowship applications for action at the New Orleans Annual Meeting. Eligible members who desire to apply for Fellowship this year are requested to submit their applications to the committee as much in advance of September 1 as possible.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Dr. Aristides Paz de Almeida, Praia de Botafogo #516, Rio de Janeiro, Brazil, S. A., Assistant in Public Health Administration, Nacional Health Department

George M. Anderson, M.D., State Capitol, Cheyenne, Wyo., State Health Officer

William F. Bushnell, M.D., Elk Point, S. D., Director, Union County Public Health Unit

Herschel G. Cole, M.D., City Hall, Hammond, Ind., Health Commissioner

George F. Cook, M.D., 4 E. Main St., Plainville, Conn., Public Health Officer

H. R. DuPuy, M.D., County Health Dept., Annapolis, Md., Senior Assistant Deputy State Health Officer

Frank C. Genouese, M.D., Patterson, N. Y., Local Health Officer

Victor F. Krakes, M.D., Keeseville, N. Y., Local Health Officer

George W. Mast, M.D., 1258 Agnes Place, Memphis, Tenn., Student, Vanderbilt University, County Health Officer Appointee in Mississippi

William H. Meyer, M.D., 27 Hooker Ave., Poughkeepsie, N. Y., Health Officer

Arthur J. O'Leary, M.D., 601 E. 167 St., Bronx, N. Y., Assistant Sanitary Superintendent, New York City Dept. of Health

Edgar F. Powell, M.D., Broad St., Fishkill, N. Y., Health Officer

William P. Richardson, M.D., C.P.H., Chapel Hill, N. C., Health Officer, Orange-Person District Health Dept.

Clarence H. Sanford, M.D., Tan Lane, Exeter, N. H., Medical Director, Exeter Academy

Jerome B. Trichter, 10 Monroe St., New York, N. Y., Inspector of Foods, New York City Dept. of Health

Gregory J. Van Beeck, M.D., U. S. Quarantine, Rosebank, S. I., N. Y., Surgeon, U. S. Public Health Service

Laboratory Section

George E. Bliven, 36 St. John St., Goshen, N. Y., Laboratory Director, J. F. DeVine Laboratories, Inc.

William H. Dickinson, City Hospital, Columbus, Ga., City Bacteriologist

Manuel Garcia Hernandez, Phar.D., Calle "G" #6, Vedado, Habana, Cuba, Director, National Laboratory, Instituto Finlay

Maurice C. Hall, Ph.D., D.V.M., National Institute of Health, U. S. Public Health Service, Washington, D. C., Chief, Division of Zoölogy

Lee Howard, M.D., 5 Derenne Apts., Savannah, Ga., Pathologist, charge of Clinical Laboratory, U. S. Marine Hospital

Evelyn Huntington, C.P.H., Harland Road, Norwich, Conn., Student and Assistant in Research

J. D. Kabler, 304 Schweiter Bldg., Wichita, Kans., Director, Wichita Clinical Laboratory

Raymond E. Leach, Box 647, Parsons, Kans., Bacteriologist in charge, District Public Health Laboratory #1

Luis Vargas, M.D., Calle de la Escuela Medico-Militar #20, Mexico City, Mex., Medical Assistant, Hygiene Institute, Dept. of Health

Elizabeth M. Wood, 720 E. Cook St., Santa Maria, Calif., Bacteriologist, Santa Barbara County Health Dept.

Sophia Zurett, 373 Grider St., Buffalo, N. Y., Chief Technician, Buffalo City Hospital

Vital Statistics Section

Thomas H. Dickson, Jr., M.D., 156 E. 6th St., St. Paul, Minn., Medical Director, Minnesota Mutual Life Insurance Co.

Besse Gulick, 1420 Maryland, Springfield, Mo., Local Supervisor, U. S. Public Health Service Survey, Linn and Livingston Counties

Joseph B. Irvine, 1426 M. St., N.W., Washington, D. C., Chief, Bureau of Vital Statistics, Health Dept.

Cleo B. Nelson, (Temp. address) 2400–20 St., N.W., Washington, D. C., Director, Bureau of Vital Statistics, Dept. of Public Welfare, Boise, Ida.

Frank P. Strome, M.D., State Dept. of Health, Harrisburg, Pa., Director, Bureau of Vital Statistics

Evald Tomanek, M.D., Dr.P.H., Holeckova 12, Bratislava, Czechoslovakia, Deputy Director of Public Health of Slovakia

Public Health Engineering Section

Gerald E. Arnold, Millbrae, Calif., Water Purification Engineer, San Francisco Water Dept.

Hydrick K. Dickert, C.E., Batesburg, S. C., District Supervisor, Malaria Control, U. S. Public Health Service

Andrew A. Hall, Jr., 1336 White St., Ann

Arbor, Mich., Student—Potential Public Health Engineer

John C. Kucharik, 4953 Elston Ave., Chicago, Ill., Sanitary Engineer, Board of Health

Albert P. Learned, C.E., 4706 Broadway, Kansas City, Mo., Sanitary Engineer, Black & Veatch

Emanuel H. Pearl, 1613 Sabine St., Austin, Tex., District Sanitary Engineer, State Dept. of Health

Evan A. Sigworth, 230 Park Ave., New York, N. Y., Research Engineer, Industrial Chemical Sales Co.

Industrial Hygiene Section

Marion E. Brown, M.D., 921 Canal St., New Orleans, La., Professor of Ophthalmology, Tulane University

William L. Clay, 510 Powers Bldg., Rochester, N. Y., interested in occupational diseases

Warren A. Cook, State Dept. of Health, Hartford, Conn., Chief Industrial Hygienist

Milton H. Kronenberg, M.D., 104 S. Michigan Ave., Chicago, Ill., Occupational Disease Clinic, University of Illinois

Anthony M. Lotowycz, C.P.H., 160 N. 5th St., Brooklyn, N. Y., Assistant Areal Supervisor, U. S. Public Health Service

Food and Nutrition Section

Charles A. Fulle, Jr., 6 Macopin Ave., Upper Montclair, N. J., Nutritional Health Education

Guillermo Lage y Fernandez, M.D., C.P.H., Prado 124 Habana, Cuba, Director, Auxiliar de Investigaciones Cientificas, Instituto Finlay

August J. Pacini, Ph.D., 155 E. Ohio St., Chicago, Ill., Nutrition Research, Pacini Laboratories

Child Hygiene Section

William W. Britt, M.D., 135 Adam St., Tonawanda, N. Y., Medical Supervisor of City Schools

Martha L. Clifford, M.D., C.P.H., State Dept. of Health, Hartford, Conn., Assistant Director, Bureau of Child Hygiene

Vincent Ippolito, M.D., 29 Spring St., New York, N. Y., Clinical Assistant Physician, Gouverneur Hospital

Vera H. Jones, M.D., 930 Monroe St., Denver, Colo., Director, Division of Maternity and Child Health

John O. McCall, D.D.S., 422 E. 72 St., New York, N. Y., Director, Murry and Leonie Guggenheim Dental Clinic

Joseph C. Palmer, M.D., 130 W. Genesee St., Syracuse, N. Y., Health Director, Public Schools

Harry Strusser, D.D.S., 6807 Clyde St., Forest Hills, L. I., N. Y., Chief, Division of Dental Service, New York City Dept. of Health

Lucy P. Sutton, M.D., 168 E. 74 St., New York, N. Y., School Physician

Public Health Education Section

Raymond G. Hollis, M.D., Taos, N. Mex., Medical Dept., U. S. Indian Service

Public Health Nursing Section

Henrietta W. Bonheyo, 1084 Blueridge Ave. N.E., Atlanta, Ga., Territorial Supervisor, Metropolitan Life Insurance Co., Nursing Service

Eleanor C. Busier, Maple St., South Dayton, N. Y., Staff Nurse, Cattaraugus County Dept. of Health

Clara M. Chitwood, 7 Elizabeth, Ellicottville, N. Y., Staff Nurse, Cattaraugus County Dept. of Health

Myrtis M. Coltharp, R.N., American Red Cross, Civic Auditorium, San Francisco, Calif., Nursing Field Representative

Mary C. Connor, 2308 Ashmead Place N.W., Washington, D. C., Director, Public Health Nursing Course, School of Nursing, Catholic University

Jessie W. Faris, 3015 E. Broad St., Richmond, Va., formerly Staff Nurse, City Board of Health

Lillian Greene, Box 213, Walnut Ridge, Ark., Public Health Nurse, Lawrence County

Elizabeth M. Hill, R.N., American Red Cross, Washington, D. C., Nursing Field Representative

Zeda D. Loveless, Davidson County Health Dept., Nashville, Tenn., Staff Nurse

Elsie E. McMahon, R.N., 349–6th, Huron, S. D., School Nurse

Aline S. Mergy, 438 N. 9th St., Terre Haute, Ind., Director, Public Health Nursing Assn.

Mary V. Pagaud, 4400 Dauphine St., Army Base #3, New Orleans, La., Superintendent of Nurses, Child Welfare and Community Health Assn.

Mary L. Railey, 3435 Upperline St., New Orleans, La., Executive Secretary, Child Welfare and Community Health Assn.

Abbie R. Weaver, Capitol, Atlanta, Ga., Nurse, State Dept. of Public Health

Epidemiology Section

Antonio D. Albertini, M.D., Ave. de Bruselas #20, Reparto Kohly, Marianao, Habana, Cuba, President, Finlay Institute.

Clifford R. Eskey, M.D., Rm. 204, Federal Office Bldg., San Francisco, Calif., Investi-

gating Sylvatic Plague in western states, *U. S. Public Health Service*

Charles F. McKhann, M.D., 300 Longwood Ave., Boston, Mass., Assistant Professor of Pediatrics and Communicable Diseases, Harvard School of Public Health

Pedro Nogueira, M.D., c/o Dr. Carr, Apartado 157, Havana, Cuba, Field Director, Comision de Malaria de Cuba

Unaffiliated

N. Talley Ballou, D.D.S., State Dept. of Health, Richmond, Va., Director of Mouth Hygiene

Walter T. Davis, M.D., Joe Wheeler Dam, Ala., with Tennessee Valley Authority

Mihkel Kask, M.D., Institute of Hygiene, University of Tartu, Tartu, Estonia, First Assistant

Paul A. Lembcke, M.D., 79 Madison Ave., New York, N. Y., Assistant Director of Medical Care, F.E.R.A.

Kenneth M. Wilson, 386-4th Ave., New York, N. Y., *Finacial Secretary*, New York Tuberculosis and Health Assn.

DECEASED MEMBERS

Carroll Fox, M.D., Rosebank, S. I., N. Y., Elected Member 1915, Fellow 1922

J. E. Rush, M.D., Pittsburgh, Pa., Elected Member 1914, Fellow 1922

P. A. Bendixen, M.D., Davenport, Ia., Elected Member 1934

Edward L. Kingman, M.D., Newton, Conn., Elected Member 1935

Annie D. MacRae, M.D., San Francisco, Calif., Elected Member 1920

Cesar Molinas Opisso, Barcelona, Spain, Elected Member 1933

Mabel L. Smyth, Honolulu, T. H., Elected Member 1928

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Fellowship and Membership, and the Governing Council will take place between now and the time of the New Orleans Annual Meeting.

HEALTH OFFICERS SECTION

Henry D. Chadwick, M.D., Boston, Mass.

Raymond D. Fear, M.D.. Dr.P.H., Stamford, Conn.

Andrew J. Krog, Plainfield, N. J.

James R. McEachern, M.D., Tampa, Fla.

K. E. Miller, M.D., Evanston, Ill.

William H. F. Warthen, M.D., Baltimore, Md.

LABORATORY SECTION

Chester S. Bowers, B.S., Hartford, Conn.

Thomas D. Kendrick, M.D., D.P.H., Rochester, Minn.

VITAL STATISTICS SECTION

Robert J. Vane, New York, N. Y.

PUBLIC HEALTH ENGINEERING SECTION

Thomas R. Camp, B.S., S.M., Cambridge, Mass.

Malcolm Pirnie, S.B., M.C.E., New York, N.Y.

FOOD AND NUTRITION SECTION

Milton E. Parker, S.B., Danville, Ill.

CHILD HYGIENE SECTION

Arville O. DeWeese, M.D., Kent, O.

Martha M Eliot, M.D, Washington, D C.

PUBLIC HEALTH EDUCATION SECTION

Thomas G. Hull, M.S., Ph.D., Chicago, Ill.

Lucy S. Morgan, M.S., M.A., New Haven, Conn.

PUBLIC HEALTH NURSING SECTION

Geneva F. Hoilien, Ithaca, N. Y.

Lillian A. Hudson, B.S., A.M., New York, N. Y.

Donna M. Pearce, B.S., R.N., Nashville, Tenn.

EPIDEMIOLOGY SECTION

Arthur H. Cummings, M.D., C.P.H., Albany, N. Y.

Frederick S. Leeder, M.D., D.P.H., Coldwater, Mich.

James E. Perkins, M.D., Dr.P.H., Amsterdam, N. Y.

Milton V. Veldee, M.S., M.D., Washington, D. C.

UNAFFILIATED

George Baehr, M.D., New York, N. Y.

George B. Darling, Dr.P.H., Battle Creek, Mich.

Charles G. Giddings, Jr., M.D., Atlanta, Ga.

Frank Kiernan, A.B., New York, N. Y.

Eleanor J. Macdonald, A.B., Boston, Mass.

Robert E. Wodehouse, M.D., D.P.H., Ottawa, Ont., Canada

NEWS FROM THE FIELD

UNIVERSITY OF CALIFORNIA AT LOS ANGELES—SUMMER SESSION

SUMMER school courses in Public Health and Nursing Education are being given at the University of California at Los Angeles as follows:

June 27–August 7, 1936

- Elementary Epidemiology
- Vital Statistics
- Principles and Practice of Public Health Nursing
- Principles of Supervision in Public Health Nursing
- Administration of Schools of Nursing
- Principles of Nursing Education
- Administration of the School Health Program
- Essentials of Nutrition
- The Relation of Diet to the Treatment of Disease
- Social Case Work
- Principles of Teaching as Applied to Home Hygiene Courses
- Methods in Teaching Home Hygiene Courses
- Maternal and Child Welfare

For information, write to the Dean of the Summer Session of the University, 405 Hilgard Avenue, Los Angeles, Calif.

WAGNER COLLEGE

A COURSE in bacteriology will be offered in the Summer Session of Wagner College, Staten Island, N. Y., from July 6 to August 15.

It is stated that this course is to be of particular interest to college students majoring in the biological sciences and to public health workers, and is a prerequisite for courses in serology, clinical pathology, and blood chemistry, offered in the fall and spring sessions as part of the curriculum for laboratory technicians.

HARVARD PUBLIC HEALTH DEGREES FOR WOMEN

WOMEN will be permitted to take degrees at the School of Public Health of Harvard University.

In the past, women have been eligible for the Certificate of Public Health upon completion of a course of study at the School of Public Health. Now they may become candidates for the degree of Doctor of Public Health or Master of Public Health, on the same basis as men students. In order to become candidates for either degree applicants must satisfy the Administrative Board of their academic fitness by a medical degree or its equivalent, from an approved medical school.

FELLOWSHIPS IN PUBLIC HEALTH

MORLEY B. BECKETT, M.D., of Lansing, Mich., member A.P.H.A., has been appointed to the staff of the W. K. Kellogg Foundation to work out the details for a fellowship system to enable graduate students in public health administration and kindred fields to obtain practical experience, it is reported.

Two full-time fellowships are now being planned, for which applicants must be graduates of recognized schools with special training in the public health field. Dr. Beckett plans to devote six months to the development of these fellowships.

Dr. Beckett, formerly Director of County Health Administration of the Michigan State Health Department, has served with the Health Department of Cleveland, as Assistant Health Commissioner of Saginaw, and Health Officer of Isabella County, Mich.

NORTHWESTERN UNIVERSITY SAFETY RESEARCH

AN Institute of Public Safety has been established at Northwestern University, to be financed by the Automobile Manufacturers' Association and

the university. It will be a research laboratory for traffic safety problems and headquarters for the traffic control program of the International Association of Chiefs of Police.

The Institute will coöperate with the National Safety Council in its campaign for traffic death reduction, install traffic accident prevention bureaus in selected cities and states, provide traffic information service to police departments, and assist in improving traffic curricula by coöperating with Harvard University's accident prevention bureau and other agencies.

Franklin M. Kreml, police lieutenant in Evanston, Ill., which has won the National Safety Council's "safest city" award three times in the last 4 years, was appointed Director of the Institute.—*J.A.M.A.*, May 2, 1936.

CONGRESS OF JEWISH PHYSICIANS

THE first World Congress of Jewish Physicians was held in Jerusalem at the Hebrew University in Tel Aviv on April 21–24.

The program included reports on the situation of Jewish physicians; reports on medical education, hygienic conditions of the Jewish population in Palestine and other countries with large Jewish population, Jewish institutions for preventive medicine and sanitary service, foundation of a world union of Jewish physicians, and scientific lectures on anthropology and eugenics.

MASSACHUSETTS NEW HEALTH UNIT

A NEW health unit has been organized in Franklin County to serve the towns of Monroe, Rowe, Heath, Charlemont, Irving, and Shutesbury, Mass.

The unit, which began to function April 1, will be maintained by federal and state funds until other towns join, it was reported. Walter W. Lee, M.D., member A.P.H.A., of North Adams, Mass., is in charge.

DR. LONG ELECTED PRESIDENT OF NATIONAL TUBERCULOSIS ASSOCIATION

AT the meeting of the National Tuberculosis Association, at New Orleans in April, Esmond R. Long, M.D., member A.P.H.A., Director of the Henry Phipps Institute of the University of Pennsylvania, was elected President of the National Tuberculosis Association, to succeed James J. Waring, M.D., member A.P.H.A., of Denver, Colo.

Hugh S. Cumming, M.D., Fellow A.P.H.A., former Surgeon General of the U. S. Public Health Service, was elected an honorary member. The Trudeau Medal of the Association was awarded to Dr. Edward W. Archibald, Professor of Surgery at McGill University, Montreal, and Consulting Surgeon at the Royal Victoria Hospital for his work on thoracic surgery.

METROPOLITAN HEALTH OFFICERS CONFERENCE

HEALTH officers of three states, New York, Connecticut, and New Jersey, met June 5 at the New York City Health Department offices and organized the Metropolitan Health Officers Conference. Its aim is to bring to the metropolitan area greater uniformity in administrative procedure in public health, closer coöperation in health problems, and closer personal relationships.

Matthias Nicoll, Jr., M.D., Fellow A.P.H.A., Commissioner of Health of Westchester County, N. Y., was elected temporary chairman of the conference, and Charles F. Bolduan, M.D., Fellow A.P.H.A., Director of the Bureau of Health Education of the New York City Health Department, was named temporary executive secretary.

This session was devoted to three main topics: Rabies and the Dog Control Problem; Food Poisoning—pastry products mainly; and Milk Grading.

NEW YORK ILLEGITIMACY BILL SIGNED

GOVERNOR LEHMAN signed a bill, on June 4, designed to help remove the stigma of illegitimacy from children born out of wedlock by providing that State birth certificates need not disclose the marital name or status of the mother.

Provision is made in the bill, which was drafted by a special commission appointed by Governor Lehman, that there shall be no specific statement on the birth certificate as to whether the child was born in wedlock or not.

HOMER FOLKS TUBERCULOSIS HOSPITAL

THE New York State Legislature recently passed a bill providing that the new State Tuberculosis Sanatorium located at Oneonta, N. Y., should be named the Homer Folks Tuberculosis Hospital, in honor of Homer Folks, F.A.P.H.A., for many years Secretary of the State Charities Aid Association, New York, and member of the New York Public Health Council. The new hospital is to be dedicated in July by Governor Lehman.

The first of the new tuberculosis hospitals recently opened by New York State has been named after the late Dr. Hermann M. Biggs, former State Commissioner of Health.

STUDENT HEALTH SURVEY

STUDENTS entering the University of California and Leland Stanford University, Calif., in the fall of 1935, are to be the subject of a 10 year study, according to the *Bulletin* of the National Tuberculosis Association. The physical histories of these students, numbering about 5,000, will be kept in the two universities, and follow-up records will be kept following graduation.

A permanent research committee has been established with representatives of all supporting tuberculosis associations participating, together with representatives of the student health services in the universities and a research adviser.

The expense of the research is to be borne by the regional tuberculosis associations and by the institutions coöperating.

SOUTH CAROLINA HEALTH OFFICERS

NEW Health Officers for districts and counties in South Carolina have been announced as follows:

Dr. Gordon R. Westrope, of Columbia, S. C.—Cherokee County

Dr. John Y. O'Daniel, of Erwin, Tenn.—Marlboro County

Dr. George Fletcher Reeves, of Goldsboro, N. C.—Colleton County

Dr. Edward P. White, of Gaffney, S. C.—Richland County

Dr. William Burns Jones, of Columbia, S. C.—Chester and Union Counties

Dr. Thomas B. Phinizy, of Augusta, Ga.—Bamberg, Allendale, and Barnwell Counties

OHIO HEALTH DEPARTMENTS MERGE

THE Hocking and Vinton County Health Departments have merged, forming a new district health department, under the supervision of Dr. Walter B. Lacock, Health Commissioner of Hocking County.

Dr. Herbert D. Chamberlain, of McArthur, Ohio, Health Officer of Vinton County, will retire.

PERSONALS

FRIEND LEE MICKLE, F.A.P.H.A., of Hartford, Conn. (Secretary of the Laboratory Section, A.P.H.A.), received the honorary degree of Sc.D. at the 25th Commencement of Allegheny College, Meadville, Pa., on June 8.

CHARLES F. WILINSKY, M.D., Fellow A.P.H.A., of Boston, Mass., has been appointed Chairman of the Committee on Public Health Relations of the American Hospital Association. His predecessors were Surgeon General Hugh S. Cumming, M.D., and Milton J. Rosenau, M.D.

G. HOWARD GOWEN, M.D., member A.P.H.A., on July 1 assumes the duties of Assistant Epidemiologist, in the Illinois Department of Public Health, Springfield. He will continue his affiliation with the University of Illinois College of Medicine in Chicago.

ANNA W. WILLIAMS, M.D., F.A.P.H.A., formerly Assistant Director of the Research Laboratory of the New York City Department of Health, received on April 27, in recognition of her 40 years of service to New York City, a testimonial scroll presented by the Women's Medical Society of New York State. The presentation was made by S. Josephine Baker, M.D., F.A.P.H.A., President of the Society.

EDWIN O. JORDAN, PH.D., F.A.P.H.A., Professor of Bacteriology and Chairman of the Department at the University of Chicago, has been elected a member of the National Academy of Science.

RICHARD ARTHUR BOLT, M.D., DR.P.H., F.A.P.H.A., Director of the Cleveland Child Health Association, and Associate in Pediatrics and in Public Health and Hygiene at Western Reserve University, Cleveland, Ohio, is conducting courses in Elementary Epidemiology, Vital Statistics, and Administration of the School Health Program, in the Summer School of Public Health and Nursing Education, of the University of California at Los Angeles, this summer.

DR. MARSHALL C. BALFOUR, representative in Greece of the International Health Board of the Rockefeller Foundation, according to the *Journal of the American Medical Association,* has been awarded the Silver Medal for Distinguished Services by the Greek Academy of Sciences, Arts and Letters, in recognition of research in the field of malaria control.

R. G. BEACHLEY, M.D., F.A.P.H.A., who for years has been Deputy State and County Health Officer at Chestertown, Md., has accepted a position as Deputy Director of Rural Health for Virginia at Abingdon, with 14 counties in his district.

DR. FRANK W. PARKER, JR., has been appointed Health Officer of the Tenth Health District of New Mexico, with headquarters at Silver City, N. M.

DR. EDWARD ROBINSON BALDWIN, Director of the Edward L. Trudeau Foundation, Saranac Lake, N. Y., was presented with the Kober Medal at the annual meeting of the Association of American Physicians in Atlantic City, N. J., May 6. The medal is awarded each year.

ALVIN R. LAMB, PH.D., formerly of the U. S. Public Health Service and the Leprosy Investigation Station, Honolulu, has become research associate at the Experiment Station of the Hawaiian Sugar Planters' Association, Honolulu.

KARL F. MEYER, PH.D., F.A.P.H.A., Director of the Hooper Foundation for Medical Research, University of California Medical School, San Francisco, Calif., received the honorary degree of Doctor of Medicine. This was conferred on him by the College of Medical Evangelists, of Los Angeles, on April 23.

DR. WILLIAM E. STEELE, of Olympia, Wash., has been appointed Medical Director in the Washington State Department of Labor and Industries, to succeed Dr. Harry Eugene Allen, of Seattle, resigned. Dr. Harry L. Leavitt, of Seattle, has been appointed Assistant Director to succeed Dr. Steele.

JAMES THOMAS CULBERTSON, PH.D., instructor in bacteriology, Columbia University, New York, has received a fellowship from the John Simon Guggenheim Memorial Foundation for study of immunity against para-

sitic diseases at the London School of Hygiene and Tropical Medicine. Michael Heidelberger, Ph.D., associate professor of biologic chemistry at Columbia, received a renewal of a grant for study of immune reactions.

DR. AUGUSTUS L. L. BAKER, of Dover, N. J., has been appointed a member of the New Jersey State Board of Health, to succeed Dr. Samuel A. Cosgrove, of Jersey City, whose term expired.

HENRY C. GAHAGAN, M.D., of Shreveport, La., has been appointed Director of the Coushatta Health Unit, succeeding Bernard Hochfelder, M.D., member A.P.H.A., resigned.

LEONARD A. DEWEY, M.D., member A.P.H.A., of Portales, N. M., who has been Acting Health Officer of the Tenth Health District of New Mexico, with offices at Silver City, N. M., has been appointed Epidemiologist in the New Mexico State Health Department.

EDYTHE P. HERSHEY, M.D., member A.P.H.A., Director of Health in the Dallas public schools, has been appointed Director of the Child Health and Maternity Divisions of the Texas State Health Department.

DR. ROBERT J. JAEHNE, of Austin, was recently named Health Officer of Travis County, Tex.

DR. MACK I. SHANHOLTZ, of Beckley, W. Va., has been appointed Director of the health district comprising Bristol and Washington Counties, with headquarters at Bristol, Va.

CHARLES L. SAVAGE, M.D., member A.P.H.A., of Charlottesville, has been appointed Director of the Buchanan-Russell-Tazewell Health District, with headquarters at Richlands, Va.

DR. ROBERT J. LANNING, of Junction City, has been named County Physician and Health Officer of Geary County, Kans., succeeding the late William S. Yates, M.D., member A.P.H.A.

GUY R. POST, M.D., member A.P.H.A., Director of the tricounty health unit of Newaygo, Oceana, and Lake Counties, with offices at White Cloud, Mich., has been named to a similar position with a newly organized unit in Mecosta and Osceola Counties, with headquarters in Big Rapids.

DR. NINA C. WILKERSON has been appointed Health Officer of Sturgis, Mich., succeeding Dr. Charles G. Miller.

DR. NEAL J. MCCANN has been named Health Officer of Ishpeming, succeeding Dr. Joseph P. Bertucci.

THEODORE MEYER, M.D., DR.P.H., member A.P.H.A., Health Officer of Van Buren County, Mich., has been appointed Health Officer of St. Louis County, with headquarters at Clayton, Mo.

DR. WILLIAM M. TAPPAN has been appointed Health Officer of Holland, Mich., succeeding Dr. William Westrate.

FREDERICK FULLER RUSSELL, M.D., F.A.P.H.A., lecturer in Preventive Medicine and Hygiene and Epidemiology, Harvard Medical School, Boston, and formerly Director of the International Health Division of the Rockefeller Foundation, has been awarded the Public Welfare Medal of the National Academy of Sciences.

THURMAN B. RICE, M.D., F.A.P.H.A., Assistant Director of the Indiana State Health Department, has been named Director of Physical and Health Education in charge of the new program of child health that has been announced for the public schools of Indiana as part of the state's activities in connection with the federal government's social security plan.

LESLIE A. LAMBERT, M.D., member A.P.H.A., City Health Officer of Flint, Mich., became Head of the State Bureau of the local health service in Idaho, a job corresponding to state health officer.

DR. SHALER A. RICHARDSON, of Jacksonville, Fla., has been appointed a member of the Florida State Board of Health, succeeding the late Harry Dash Johnson, of Daytona Beach.

HARRY R. DESILVA, PH.D., of Amherst, Mass., has resigned as professor of psychology in charge of the psychologic laboratory, Massachusetts State College, to join the staff of the Bureau for Street Traffic Research of Harvard University.

DR. EDWIN M. MAHONEY was elected Secretary of the newly appointed Health Board of Holyoke, Mass. Other members are Arthur Hebert, Chairman, and Dr. Joseph W. Wonsik.

DR. HENRY C. LINDERSMITH, of Sherwood, Ohio, has been appointed Health Officer of Defiance County.

DR. CHARLES J. HATFIELD, Director of the Henry Phipps Institute, University of Pennsylvania, Philadelphia, Pa., has been appointed official representative of the National Tuberculosis Association for the conference of the International Union Against Tuberculosis to be held in Lisbon, Portugal, September 7–10.

CHARLES P. DRURY, M.D., member A.P.H.A., for 8 years secretary of the county medical society, was appointed Health Officer of Marquette, Mich., effective April 1, succeeding the late Frederick McD. Harkin, M.D., member A.P.H.A.

DR. WELLS F. SMITH, of Little Rock, has been elected President of the Arkansas State Board of Health.

DR. CHARLES D. LIPSCOMB, of Quitman, Tex., was recently appointed Health Officer of Wood County.

DR. HOWARD E. M. BOOCKS, of Logan, Ohio, has been appointed Health Officer of Logan County.

DR. JOHN B. H. BONNER, of Beaumont, Va., was appointed Director of the Sussex County Health District, with headquarters in Stony Creek.

DR. JOHN S. COOPER, of Greenville, Tex., has been appointed City Health Officer, to succeed Dr. Benjamin F. Arnold.

ELMER G. BALSAM, M.D., member A.P.H.A., of Billings, Mont., has been reappointed a member of the Montana State Board of Health.

DR. LAWRENCE ISENHART has been named to succeed Dr. Samuel P. Colehour, resigned, as Health Officer of Mount Carroll, Ill.

DR. WALTER E. MERCER, for 4 years Health Officer of Webberville, Mich., has been placed in charge of the Bureau of Child Health of the Lansing Department of Health.

DEATH

CARROLL FOX, M.D., F.A.P.H.A., Head of the U. S. Quarantine Station at Rosemont, S. I., N. Y., died on May 14. He has been a member of the A.P.H.A. since 1915 and was a Charter Fellow. He served in the U. S. Navy during the War, and later entered the U. S. Public Health Service. C. V. Atkin, M.D., will take over the direction of the Quarantine Station pending an official appointment in Washington.

WILLIAM S. YATES, M.D., member A.P.H.A., Health Officer of Geary County, with offices at Junction City, Kans., died recently.

FREDERICK MCD. HARKIN, M.D., member A.P.H.A., of Marquette, Mich., died in March, 1936.

JAMES H. PAUL, M.D., of Jamesville, N. Y., died recently. Dr. Paul had been Health Officer of Dewitt since 1912.

CONFERENCES AND DATES

June 6–Nov. 29, Medical Exhibit "Story of Life," in Texas Centennial Exposition, Dallas, Tex.

June 15–Aug. 21, Speech Conference, University of Denver, Denver, Colo.

July, Third International Conference on Social Work Problems, London.

July 9–20, Exhibit of Educational Publications, New York University (Summer Session), 29 Washington Place, New York, N. Y.

July 6–10, 29th Annual Meeting of the American Home Economics Association, Olympic Hotel, Seattle, Wash.

July 6–11, The Royal Sanitary Institute, Southport, England.

July 13–17, American Dental Association, San Francisco, Calif.

July 15–17, League of South Dakota Municipalities, Rapid City, S. Dak.

July 18–23, Third International Open Air School Congress, Bielefeld and Hanover, Germany.

July 19–23, International Convention for the Health of University Students, Athens, Greece.

July 20–24, Oklahoma Water and Sewage Conference, Stillwater, Okla.

July 25–Aug. 1, The Second International Congress of Microbiology, London.

July 27–29, Annual Meeting, Union of Canadian Municipalities, Vancouver, B. C.

Aug. 2–8, Annual Meeting, National Institute for Commercial and Trade Organization Executives, Northwestern University, Evanston, Ill.

Aug. 11–14, American Veterinary Medical Association, Deshler-Wallick Hotel, Columbus, O.

Aug. 16–22, National Hospital Association, Philadelphia, Pa.

Aug. 16–22, National Medical Association, Philadelphia, Pa.

Aug. 18–20, League of Iowa Municipalities, Davenport, Iowa.

Aug. 19–21, Annual Meeting—Central States Section, American Water Works Association, Hotel Cleveland, Cleveland, Ohio

Aug. 29–Sept. 6, Third Postgraduate Course of the International Hospital Association, Prague, Czechoslovakia.

Aug. 31–Sept. 12, Harvard Tercentenary Conference of Arts and Sciences, Cambridge, Mass.

Sept. 2–4, Annual Convention, Union of Nova Scotia Municipalities, Digby, Nova Scotia.

Sept. 2–4, Annual Meeting, Ontario Municipal Association, Toronto, Ont.

Sept. 7–10, International Union Against Tuberculosis, Lisbon, Portugal.

Sept. 7–12, Third World Power Conference, National Power Policy Committee, Department of the Interior Building, Washington, D. C.

Sept. 14–17, Annual Convention, League of California Municipalities, Santa Monica, Calif.

Sept. 14–17, Annual Meeting, California Sewage Works Association, Santa Monica, Calif.

Sept. 15–30, First International Congress of Sanatoria and Private Nursing Homes; Margitsziget, Sanatorium, Budapest, Hungary.

Sept. 21–23, Annual Convention, American Institute of Park Executives and the American Park Society, South Bend, Ind.

Sept. 21–23, Annual Meeting, Rocky Mountain Section—American Water Works Association, Denver, Colo.

Sept. 22–25, Annual Meeting—New England Water Works Association, Pennsylvania Hotel, New York, N. Y.

Sept. 23–25, Annual Meeting of the New York State Association of Dairy and Milk Inspectors, Van Curler Hotel, Schenectady, N. Y.

Sept. 23–26, Mississippi Valley Conference on Tuberculosis, The Mississippi Valley Sanatorium Association,

Hotel Pere Marquette, Peoria, Ill.

Sept. 24–25, Annual Meeting, League of Wisconsin Municipalities, Manitowoc, Wis.

Sept. 28–30, Public Works Congress—American Society of Municipal Engineers—International Association of Public Works Officials, Toronto, Ont.

Sept. 28–Oct. 2, American Hospital Association, Cleveland, O.

Oct. 5–9, Annual Safety Congress and Exposition, National Safety Council, Atlantic City, N. J.

Oct. 10–18, National Dairy Show, Dallas, Tex.

Oct. 12–15, Annual Convention—Southwest Section, American Water Works Association, Fort Smith, Ark.

Oct. 12–17, The Dairy Industries Exposition, Atlantic City, N. J.

Oct. 12–18, Third International Congress on Malaria, Madrid, Spain.

Oct. 14–16, Annual Convention, Pennsylvania Water Works Association, Haddon Hall, Atlantic City, N. J.

Oct. 14–17, Annual Civil Service Assembly of the United States and Canada, Cincinnati, Ohio.

Oct. 17–25, Centennial Exposition Dairy Show, Atlantic City, N. J.

Oct. 19–21, Annual Meeting, International City Managers' Association, Richmond, Va.

Oct. 20–23 (Tues., Wed., Thurs., Fri.), Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Oct. 20–23, American Association of School Physicians, Hotel Roosevelt, New Orleans, La.

Oct. 21–23, Ontario Hospital Association, Toronto, Ont.

Oct. 26–28, Annual Meeting—Missouri Valley Section, American Water Works Association, Kansas City, Mo.

Oct. 26–28, National Association of Exterminators & Fumigators, Cleveland, Ohio.

Oct. 26–28, Annual Meeting, North Carolina Section—American Water Works Association, Hotel Charlotte, Charlotte, N. C.

Oct. 29–31, Annual Meeting of the Association of Military Surgeons, Detroit, Mich.

Nov. 8–11, Annual Meeting, National Association of Commercial Organization Secretaries, Omaha, Nebr.

Nov. 9–12, Association of Dairy, Food and Drug Officials of the United States, Miami Biltmore Hotel, Coral Gables, Fla.

Nov. 9–15, American Education Week. Write: Educational Press Assn., N. J. *Educational Review,* 605 Broad Street, Newark, N. J.

Nov. 11–13, Refrigeration Service Engineers Society, Hotel Gayoso, Memphis, Tenn.

Nov. 17–20, Southern Medical Association, Baltimore, Md.

Dec. 28–30, Society of American Bacteriologists, Indianapolis, Ind.

Positions Wanted

LABORATORY

Young woman, graduate University of Maryland, desires position as bacteriologist. Available now. L-251

Young man, six years' experience as director of laboratory of city health department, 4 years owner and manager of a private laboratory, desires position as bacteriologist, chemist or sanitary inspector. L-252

Young woman, A.B. Bates College; several years' experience in various state laboratories, desires position as bacteriologist. L-253

Woman, graduate North West Institute of Medical Technology; 2 years' experience as technician in private laboratory; is available now for position as laboratory technician and general office worker. L-256

Woman physician, M.D. Johns Hopkins Medical School, Dr.P.H. Johns Hopkins School of Hygiene and Public Health; 10 years' experience as pathologist and director of laboratory in a sanatorium; is interested in a position involving the bacteriology of the tubercle bacilli. L-257

Man, with M.S. major in Bacteriology and Biochemistry, desires position with University, Health Department or Biological House. Five years' experience as research assistant in bacteriology and serology in a Class A Medical School. L-210

MISCELLANEOUS

Woman physician, M.D. Boston University, Graduate work in health education in Columbia University and Massachusetts Institute of Technology; ten years' experience in college health work and teaching; some experience in child hygiene, psychiatry and with delinquent women; desires a position in school, college, child welfare or institutional work. M-248

Woman physician, M.D. Indiana University School of Medicine; 13 years' experience as the director of child hygiene in a state department of health, experience in adult education both as a teacher and administrator; desires position in health education or child hygiene. M-249

Young physician, M.D. University of Berlin, licensed in New York State, is available now for a position with an industrial concern. M-254

Young woman, Ph.D. Columbia University; considerable experience in the field of health education with official, voluntary and commercial organizations, is interested in a position as Director of Public Health Education in a City, State, or Agency. Available in September. M-255

Young man, age 30, eight years' experience as milk and food inspector in large eastern city. Capable of assuming responsible position in administrative or inspectorial capacity in small or medium-sized city. Preferably in East or South. M-258

ENGINEER

Young man, graduate in engineering; several years' experience as director of a division of sanitation in a county health department; desires a position in public health engineering, administrative work preferred. E-250

HEALTH OFFICERS

Physician, M.D. Ohio State University; several years' experience in various positions with a state health department, desires position as supervisor, rural or city health administration. A-237

Physician, M.S.P.H. Columbia University, with experience in district health administration desires position as health officer or in other public health administrative capacity. A-227

Persons with medical and post-graduate education who are seeking employment are invited to communicate with the Executive Secretary in regard to several available opportunities.

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

VITAMINS IN CANNED FOODS

I. VITAMIN C

• The history of scurvy is as old as the history of exploration and conquest. Its ravages among early explorers and invaders are recorded in the oldest pages of history, due principally to the fact that during extended sea voyages or treks by land, dependence had necessarily been placed almost entirely on foods preserved by the crude methods of the day.

Scurvy was the first vitamin deficiency disease to be controlled by dietary management. In 1757, Lind recognized the fact that some substance in foods exerted a specific protective action against scurvy (1). As early as 1804, the daily lime juice ration became compulsory in the British Navy (2).

However, it remained for modern biochemical science to establish the chemical identity of this antiscorbutic factor. Vitamin C is now known to be identical with cevitamic acid (levo-ascorbic acid) and is as yet the only vitamin to be synthesized in the laboratory (3).

There would appear to be no valid reason why scurvy should ever constitute a serious threat to the health of the average American infant or adult. Development of refrigerated transportation for raw foods and improvements in modern methods of food preservation, specifically canning methods, make available to the consumer during the entire year a large variety of foods possessed of valuable vitamin C contents. In addition, the modern trend towards education of the layman, in regard to the vitamin C requirements of both the infant and the adult, should also assist in complete eradication of infantile and adult scurvy from America.

Many canned foods are to be valued as contributors of vitamin C. Nutritional research has indicated that canned products such as the citrus fruits or citrus fruit juices (4), the more common fruits (5), and vegetables or vegetable juices, are important sources of the antiscorbutic factor (6). Modern canning procedures afford a good degree of protection to this labile vitamin, with the result that the canned food can be relied upon to supply amounts of vitamin C to the diet consistent with the amounts of the vitamin originally contained in the raw food from which it was prepared.

Effective—

SMALLPOX VACCINE

Lederle

THERE WERE 8,021 CASES of smallpox reported in the United States last year. This is an increase of 2,655 cases over 1934. These figures are a national disgrace, for many foreign countries have been entirely free from smallpox for several years.

With such a satisfactory method of prevention as SMALLPOX VACCINE, the disease should be entirely eliminated in the United States.

Immunity in primary vaccination develops to the point of protection in about ten days, sooner in secondary vaccination.

SMALLPOX VACCINE *Lederle* is available in capillary tubes, each sufficient for a single vaccination, and accompanied with a sterile steel needle.

Literature upon request.

INDEX TO ADVERTISERS

Delicious Food-Drink Adds Easily Assimilated Iron to the Diet

ALSO RICHLY PROVIDES CALCIUM, PHOSPHORUS AND VITAMIN D

COCOMALT, the delicious chocolate flavor food-drink, is a rich source of available Iron. An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form.

Thus three cups or glasses of Cocomalt a day supply 15 milligrams—which is the amount of Iron recognized as the normal daily requirement.

Used as a delicious food-drink, Cocomalt provides a simple, palatable means of furnishing Iron to growing children, convalescents, expectant and nursing mothers.

...and for bones and teeth

In addition to Iron, Cocomalt is rich in Vitamin D—containing at least 81 U.S.P. units per ounce. Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation.

Cocomalt also has a rich Calcium and Phosphorus content. Each cup or glass of this tempting food-drink provides .32 gram of Calcium and .28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth: Calcium, Phosphorus and Vitamin D.

Easily digested — quickly assimilated

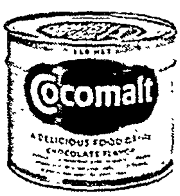
Not the least of Cocomalt's many virtues as a food-drink is its *palatability*. It is so refreshing, so delicious, it appeals even to the very sick. And though it provides exceptionally high nutritional fortification, it is easily digested, quickly assimilated, imposes no digestive strain.

Recommended by you and taken regularly, Cocomalt should prove of great value in health improvement.

Cocomalt

FREE TO DOCTORS AND NURSES

We will be glad to send a professional sample of Cocomalt to any doctor or nurse requesting it. Simply mail this coupon with your name and address.



Cocomalt is the registered trade-mark of the R. B. Davis Co., Hoboken, N. J.

R. B. Davis Co., Dept. 6-H, Hoboken, N. J.
Please send me a trial-size can of Cocomalt without charge.

Administrative Practice in the West

J. ROSSLYN EARP, Dr.P.H., F.A.P.H.A.

Director New Mexico State Bureau of Public Health, Santa Fe, N. M.

STANDARDS of administrative practice have grown up in the East and have been determined very largely by eastern experience. This was no doubt inevitable. The distance from our mountain states to the various headquarters on the eastern seaboard precludes the attendance of western health officers at committee meetings. It may also be true that the typical western states have not pioneered in health administration and have not yet had much experience to offer.

In the result, however, certain factors have not received the attention that, from a western point of view, they deserve. The factor which has been most neglected is that of population per square mile and its corollary factor is wealth per square mile.

An example will make this clear. An advisory committee to the U. S. Public Health Service, representing in its membership Chicago, Baltimore, Boston, Philadelphia, New York, Ann Arbor, and Washington, D. C., recommends[1] that venereal disease control work requires in the state health department a separate section or subdivision under the direction of a full-time officer. They even recommend that each health district should include the same provision. It is hardly conceivable that this committee could have considered or even imagined a state like New Mexico with a population of 394,863 most living at or below the level of bare subsistence and scattered over 122,635 square miles.

Despite its poverty, New Mexico probably spends more per capita on health services than most of its immediate neighbors, and it is one of only 3 states in the Union that have provided full-time public health service for all of their citizens. To do so it has had to lay down some original standards and these are hereby offered not in the belief that they are ideal but simply as a measuring rod for those who in the future may attempt to evaluate practice in the wide open spaces of the West.

Table I shows the population, assessed valuation, estimated income, and approximate area of each of the 10 health districts of the state. The column of income is included to permit comparison with the standard laid down by Smillie[2] that $10,000,000 is the minimum wealth necessary to support a full-time *county* unit. It will be seen that 2 of our districts fall short of this minimum income (estimated by the same method used by Smillie). On the other hand, the

of communicable disease occurring in such vast districts, nor can he expect any special aid from a large number of supporting personnel. Table II shows the number of such personnel assigned to each district and including those subsidized by Title V (Fund A) and Title VI of the Security Act. There are certain situations which must be investigated whatever the inconvenience and whatever the distance to be traveled. We are engaged in finding out for ourselves exactly which situations can be considered as obligatory responsibility within the framework of physical conditions imposed upon us.

Table II also shows the total contribution from tax moneys to local health work. Add to this $51,600 contributed to the state health department and $18,000 contributed in the present fiscal year to the district health officers' fund which will be carried over into the next fiscal year and therefore does not appear in the above table, and we have a per capita expenditure from taxes for health of $.50. This amount can be increased even in a poor state which has adopted a constitutional ceiling of 20 mills taxation on property. But obviously it can only be increased by great pressure and to a limited extent.

The State Health Department has no separate division in charge of (1) food and drugs, (2) dentistry, (3) industrial hygiene, (4) tuberculosis, (5) syphilis, (6) maternity and child hygiene, (7) cancer control, (8) mental hygiene. There are pressure groups, some large, some small, working for the inclusion in *every* state health department of each of these sub-divisions. We do not question the desirability of reinforcing our central organization in this way, but looking at the cost of such reinforcement and looking again at the skeleton crew that is manning our health districts, where the real spade work of public health is being done, we are bound to pause. We believe that if eastern committees will look at the same picture they will pause too.

It is admitted that the picture could be changed by federal subsidies on a much larger scale than those granted under the present Security Act. The uncertain and spasmodic generosity of the national Congress poses administrative conundrums to all state health officers and is a more serious affliction to western health officers only to the extent that intermittent charity can be more tantalizing when the stomach is habitually empty than when it is assured of regular though limited provender.

2. Smillie, Wilson G. *Public Health Administration in the United States.* Macmillan, 1935.

NOTE: The above article was prepared early in 1936, before definite allocations under the Social Security Act were known. The actual allocations have been somewhat higher than those assumed in this article with the result that part-time clerks have been turned into full-time clerks and some other minor additions made to the local staffs. Also a division of maternal and child health has been established in the central administration.

Modern Trends in Nursing Education

ANNIE W. GOODRICH, R.N., D.Sc.
Dean and Professor of Nursing (Emeritus), Yale University School of Nursing, New Haven, Conn.

NURSING education is undergoing drastic changes. History repeating herself through a new social expression has kept consistently in step with the development and progress in related fields of life activity. The demand today for a different preparation for the nurse, general and professional, is a demand not of the idealist but of the times.

It is hardly necessary to trace the evolution of nursing practice from an age-old emotional expression in response to human suffering to the present-day three-dimensional demand that adds to succor the technics required for curative medicine and a program of health education for nursing in relation to preventive medicine—the third immeasurably extending the scope of activity and the social contribution of the profession.

It is said that the Americans have no plan. This I question. Consciously and unconsciously, Americans are adhering to the slow but sound democratic principle of social growth and development, namely, education of the entire population as the *sine qua non* of efficient citizenship, the cornerstone of which is physical fitness.

In no country are there greater opportunities for the realization of the "American dream—that belief in the right and possibility of a better life for all." Institutions of higher education open wide doors through which, in ever increasing numbers, the youth of the country seek fullest preparation for their chosen life activity, and throughout the country highly equipped health and social organizations and institutions offer almost unlimited opportunities, and enough graduates of the varied types of social worker to provide the personnel demanded for adequate care and direction of the people, and for the instruction and practical experience of students in their related fields.

The opportunity of the nurse in the field of health education is now generally conceded, and for such function, emphasis has been laid on the preparation of a special group designated as public health nurses. Financial provision, however, for the practice of this group, either by private philanthropy or governmental appropriation, is entirely inadequate to meet the needs of the population, whether rural, urban, or suburban. Approximately 20,000 public health nurses are now engaged in a field that 100,000 would not adequately cover. A tragedy of the day is the inadequate employment in the medical and nursing professions, the uncared-for sick, and the unattended births in the community—the latter deplorable in a century so informed on the importance of the birth episode through its influence on the mother and child and, *ipso facto,* the future generations. Fortunately there is today an awakening appreciation of the contribution

that might be made in the field of preventive medicine by this numerically strongest division of health workers, through a curriculum shaped not for a selected group but for the entire profession.

That courses in the newer sciences, sociology, psychology, psychiatry, as well as in the physical sciences, are essential for this wider interpretation of practice, either as prerequisites or in the professional curriculum, is not open to question. The content of such courses in their application to the particular field requires much study and experimentation. The same may be said of the various branches of clinical medicine, some experience in each of which is of utmost importance if the practice of the nurse is to extend through the field of curative medicine into that of preventive medicine, as it obviously should, since the opportunity of this practitioner for health education through her intimate and sometimes prolonged association with the patient and the family equals, may even exceed, that of the public health nurse.

This expansion of function in half a century of organized existence presents a problem of curriculum readjustment greatly complicated by the conditions governing schools of nursing. The first schools in this country, established on the Nightingale plan, were conceived as separate units, though closely allied to the institutions providing a practice field. The profession, however, early lost its integrity and educational freedom by the establishment throughout the country of these schools as integral departments of the hospitals—with the asset of assured support, but the predictable result, in large measure, and in many cases entirely, of the subordination of the educational program to the needs of the nursing service rendered by the student body.

The values accruing, despite the palpable defects of the educational program, are recognized, but the insistent and increasing demands from the rapidly developing field of public health for nurses equipped to meet the health as well as the sickness needs of the community could not be disregarded. The League of Nursing Education, therefore obtained a grant from the Rockefeller Foundation that made possible the first study ever undertaken, which was directed by Josephine Goldmark, in coöperation with a representative committee of which C.-E. A. Winslow, Dr.P.H., was chairman. The findings were published in 1921 under the title "Nursing and Nursing Education in the United States." Originally conceived as a study of the supplemental subject matter required for public health nursing, a superficial survey of the undergraduate courses left no question as to the need of a searching investigation of the basic professional preparation. It was determined to extend the study to include the courses offered in 15 selected schools.

This study, a classic that will stand the test of time, was shortly followed by a more comprehensive undertaking, the purpose of which was indicated by the designation of the advisory body as the Grading Committee. Again the problems involved deflected the original intent into other channels. The first report, prepared by Dr. Burgess, a highly qualified statistician, was entitled "Nurses, Patients, and Pocketbooks." This presented to an astonished public a yearly outpouring from 2,000 schools of nursing of a graduating body that had already brought the ratio of nurses to population in some states as high as 1 to 300, and that would multiply by compound interest to an astounding figure in a comparatively few years. The report further presented the low level of general education; inadequate teaching facilities as expressed in the number and preparation of instructors; theoretical and

clinical content of curriculum and teaching equipment; and other factors bearing directly or indirectly on the preparation of workers for a field of acknowledged social importance.

Under the caption "Nursing Schools Today and Tomorrow," the Grading Committee published in 1934 a report on its further findings, but did not feel it possible to fulfil the complex task for which it was created. It is a reasonable question whether, without changes acknowledged as essential but far from achieved, grading or accrediting of the schools on so unstable a basis as now exists is advisable, despite the obvious need of reliable information for candidates. The National League of Nursing Education, through its Standards Committee and in conference with experts in education, medicine, and nursing, is studying the problem and will undoubtedly develop a plan which will clarify the situation through some form of classification.

The influence of these reports was evidenced by a steady decrease in the number of schools, and the advancement of the educational requirement for admission to completion of high school, reported as 90 per cent in the second and last publication of the Grading Committee.

Concurrently with the studies of the Grading Committee in this country, studies of nursing and nursing education were conducted in England by the *Lancet* Committee, and in Canada, under the supervision of the Canadian Medical Association and the Canadian Nurses Association, by G. M. Weir, Professor of Education in the University of British Columbia. The latter brought out the most comprehensive, sympathetic, and constructive discussion of the subject that has yet appeared.

It is not necessary to discuss in detail the defects revealed in the present system of nursing education. The number of schools still existing, approximately 1,500, is suggestive of the situation, without the very definite evidence of inadequate instruction, inadequate clinical experience, and hours of physical and mental output generally conceded as detrimental to health—in short, an educational interpretation out of step with present-day social conditions, educational methods, and scientific conclusions.

Through these several studies the profession now has a foundation of facts and analyses upon which to base future plans and programs, and through which the values intrinsic in the traditional type of nursing education may not be lost, but deepened and broadened by the vitalizing current of scientific findings bearing on the human organism. To these studies also must be attributed the very definite tendency to effect connections between schools of nursing and institutions of higher education.

This trend in the United States toward a higher level of general education and a more comprehensive professional preparation, supported by the unequivocal pronouncement of the Canadian Survey of Nursing Education, and the trends in several countries on the European Continent, leave little question as to the ultimate release of the hospitals from a burden that should never have been imposed. The curriculum in preparation for nursing in the new field of preventive medicine demands that these schools find their place in the educational system of the country, and that as definite a relation to the institutions of higher education is imperative as obtains for the allied branches of medicine, nutrition, pharmacy, dentistry, and social service. No less than for the education of the community should the State assume responsibility for its health. Privately endowed or supported schools or departments would still continue but, as in the case of other professional and voca-

tional courses in these institutions, tuition fees would be required, while working scholarships, as in other branches of the arts and sciences, could and should be made available for desirable candidates during their clinical and field experience.

Though as early as 1910 the University of Minnesota had authorized the establishment of a school of nursing as a department of the School of Medicine, this control, unfortunately, hardly less than that of the hospital, subordinated the students' program of study to the demands of the affiliated hospitals for nursing service. Had the principles and provisions clearly defined by Richard Olding Beard, M.D., to whose vision this step was attributable, been adhered to, the university relationship would have had even greater significance, for it would have established as essential for sound practice the right of schools of nursing to the academic freedom accorded other professions in the development of their program of study, and through the provision of an adequate graduate nurse staff for the affiliated hospitals, insured the student the educational value of the clinical experience.

In 1934 the League of Nursing Education published a list of 136 schools connected with universities. It is understood that 165 of the 400 Catholic schools of nursing are affiliated with Catholic colleges. In many cases, both from the academic and professional standpoints, the connection is but in name. While a number of schools have been accepted as integral units of universities or colleges, the variations in the entrance requirements and the professional curriculum are great. For instance, 2 university schools require a Bachelor's degree from an accredited college for the basic course which leads to a degree of Master of Nursing; a number of the schools require 1 or 2 years of college work for admission, while others still adhere to the completion of 4 years of high school.

Highly desirable as is the movement, the effecting of the connection of schools of nursing with institutions of higher education calls for study and direction, and to meet this demand the Association of Collegiate Schools of Nursing was recently created, the objects of which, as set forth in the constitution, are as follows:

1. To develop nursing education on a professional and collegiate level
2. To promote and strengthen relationships between schools of nursing and institutions of higher education
3. To promote study and experimentation in nursing service and nursing education

In order to extend its usefulness as widely as it consistently could, provision was made by the Association for two classes of membership, active and associate. Briefly stated:

Active membership is open to an accredited school of nursing established as a constituent part of an accredited college or university.

Associate membership is open to accredited schools of nursing, the curricula of which meet the standards set by the Association of Collegiate Schools of Nursing, and that maintain a relationship with accredited colleges or universities through which their resources and facilities are available for the students.

This association, now accepted as a constituent member of the American Council on Education, has on its list the following schools and departments of nursing:

ACTIVE MEMBERS OF THE ASSOCIATION OF COLLEGIATE SCHOOLS OF NURSING

Skidmore College School of Nursing, Saratoga, N. Y.

Yale University School of Nursing, New Haven, Conn.

Catholic University Department of Nursing Education, Washington, D. C.

George Peabody College for Teachers, Department of Nursing Education, Nashville, Tenn.

St. Louis University School of Nursing, St. Louis, Mo.

Syracuse University, Department of Public Health Nursing, Syracuse, N. Y.

Teachers College, Columbia University, Department of Nursing Education, New York, N. Y.

University of Oregon, Department of Nursing Education, Portland, Ore.

University of Virginia, School of Nursing Education, Charlottesville, Va.

Washington University School of Nursing, St. Louis, Mo.

Simmons College School of Nursing, Boston, Mass.

University of California School of Nursing, Berkeley, Calif.

University of Washington School of Nursing, Seattle, Wash.

Vanderbilt University School of Nursing, Nashville, Tenn.

Western Reserve University School of Nursing, Cleveland, Ohio

ASSOCIATE MEMBERS

Duke University School of Nursing, Durham, N. C.

Rochester University School of Nursing, Rochester, N. Y.

St. Louis University School of Nursing, St. Louis, Mo.

University of Michigan School of Nursing, Ann Arbor, Mich.

University of Oregon, Department of Nursing Education, Portland, Ore.

Washington University School of Nursing, St. Louis, Mo.

Be the selected field of her practice where or what it may, every nurse needs, as an individual, as a citizen, and as a practitioner of vital social importance, a liberal education in the fullest interpretation of the term. It is frequently asserted that so prolonged and comprehensive a preparation is not justified by the rewards in nursing as expressed in financial returns, satisfactions accruing through the services rendered, and the hours of physical output. To all these arguments the reply, based on any study of human responses, should be that the higher educational level, through the stimulation of the social and physical sciences, brings an inquiring and resourceful mind to the task—a type of mind that "seeing that which is invisible" overlooks—often too greatly overlooks—conditions that early become unbearable to the arid mind of the mechanized product of a program of education that limits knowledge to the required technics. The stultifying influences of the sometimes unpleasant procedures, repetitive almost to the point of revolt, can only be overcome by an interest and purpose that holds the attention above the drudgery of the means through which the desired end must be achieved.

But is there any life activity of which this is not the case? Furthermore, in any activity in which science is concerned—and there are few in which it is not—these very procedures often assume undreamed of significance. The failure to admit the desirability of a scientifically oriented individual for the part assigned the nurse—this connecting link between the investigator and the organism with which they are mutually concerned—is difficult to understand in the light of present-day scientific knowledge and social conditions.

In view of the unemployment of the country's greatest asset, her youth, now expressed in millions; the unemployed qualified teachers; the unemployed graduate nurses; and the ever shortening span of working years; there is little excuse for the failure to require for all workers a program of education through which the country may be better served, and their own lives enriched. In the field of nursing itself there is a wealth of dormant interest awaiting the specialists who will soon supplant the outmoded classification of private duty, institutional, and public health nurse. I refer to the specialists in nursing in surgery, medicine, nervous and mental diseases, obstetrics, and pediatrics, branches which

again fall into sub-divisions requiring for the nurse, no less than the physician, a highly specialized body of knowledge and skills.

The syntheses demanded for efficient result in the field of health can be achieved only through the intelligent, collective will of the army of health workers, specialists in their own field, but all versed in scientific concepts, scientific methods, and scientific terminology, motivated by a unified objective. That such coördinated, coöperative programs be developed was the pronouncement of the Committee on Medical Care for the American people.

An important step, and one that further emphasizes the need of broadening the content of nursing education, is the effort to persuade nurses, professionally so highly organized, to organize for service through local community programs based on the needs of and open to the entire population. To this end the national nursing organizations have recently appointed a committee that has outlined as basic the following principles:

1. That a responsible group, representing the nursing profession, the medical profession, and such lay groups concerned with nursing as hospital boards, schools of nursing committees, boards of public health nursing agencies, etc., work out plans in each community for a community nursing program.

2. Analyzing community nursing problems include:

a. How much nursing care is needed for different types of situations

b. What are the present facilities

c. What are the gaps and duplications as shown by "a" and "b"

3. Meeting community nursing needs involves:

a. Reducing the number of agencies which distribute nursing service to as few agencies as possible and providing one coördinating agency through which all types of nursing service may be obtained

b. An understood relationship and division of responsibility between the various nursing facilities

c. A concerted effort to fill in gaps and eliminate duplication

d. The establishment in every community of some type of machinery for supplying nursing service

In the Canadian Survey of Nursing Education will be found a comprehensive and suggestive consideration of municipal support and administration of community nursing service.

Of wider significance than is at first apparent are these 2 progressive steps—the attainment for schools of nursing of the rights and privileges of higher education; and the integration, for local community service, of the contributions of the members of the nursing profession.

The national and international significance of the health movement, to the furtherance of which throughout the world American citizens have so greatly contributed, cannot be overestimated, and not only through the prevention of disease that takes no cognizance of national boundaries, but through the underlying emphasis on the value of every human life as such, provided only that through heredity and environment the organism shall be well born.

Through an International Council of Nurses, American nurses have long since established professional relationships on all continents. Through the Division of International Studies of the Rockefeller Foundation, nurses from many countries have been enabled to study—through undergraduate and graduate courses, and through visits to American institutions and organizations—nursing education and nursing service in the United States. It is eminently fitting that the International Council of Nurses and the League of Red Cross Societies should unite to establish a Florence Nightingale Memorial Foundation, and that this memorial should take the form of courses for international students under the auspices of the University of London in coöperation with the hospitals and social or-

ganizations of the city in which was offered the first and world renowned professional program of nursing education. Never in the history of the world was there a more timely moment to further a project so consistently expressive of the potential value of every human life.

As in all professions, the responsibility for the interpretation of function, and the acquirement of the educational content demanded for the fulfillment of such function, rests upon nurses themselves. However obscured may be the public's understanding of the part of nursing in social reconstruction, nurses themselves, to whom the mental, physical, and social crippling of humanity is an open book, cannot plead ignorance, but, as an inalienable right, should demand the educational content through which their most effective service may be rendered and the means through which such service may be universally available. Not less than for their educational needs should the country assume responsibility for the health of her children.

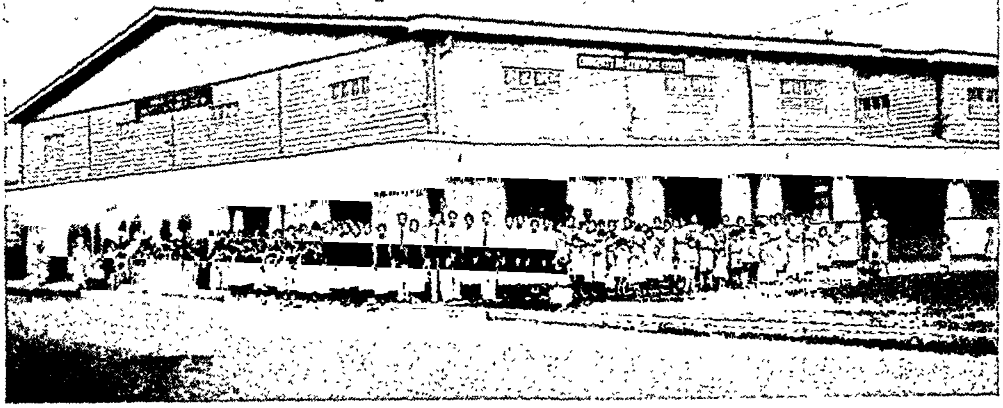
The Medical Profession

I SAID our profession was a holy office on the same level as that of the priest if not higher, where surplus money-making should be forbidden by law. The doctors should be paid by the State and well paid like the judges in England. Those who did not like this arrangement should leave the profession and go on the Stock Exchange or open a shop. The doctors should walk about like sages, honoured and protected by all men. They should be welcome to take what they liked from their rich patients for their poor patients and for themselves, but they should not count their visits or write any bills.

What was to the heart of the mother the value in cash of the life of her child you had saved? What was the proper fee for taking the fear of death out of a pair of terror-stricken eyes by a comforting word or a mere stroke of your hand? How many francs were you to charge for every second of the death-struggle your morphia syringe had snatched from the executioner? How long were we to dump on suffering mankind all these expensive patent medicines and drugs with modern labels but with roots sprung from medieval superstition? We well knew that our number of efficacious drugs could be counted on the ends of our fingers and were handed to us by benevolent Mother Nature at a cheap price.—Axel Munthe, *The Story of San Michele*, 1930.



Santa Cruz Community Health-Social Center

Community Public Health Nursing in the Philippine Islands

GEORGE C. DUNHAM, M.D., F.A.P.H.A. *

Major, Medical Corps, U. S. Army, Army Medical School, Washington, D. C.

PUBLIC health and welfare work in the Philippine Islands has been supervised by Americans during the entire period of more than 35 years of American occupation. During recent years supervision has been exercised by an American Governor-General, an American cabinet member, and an American technical adviser. On November 15, 1935, when the new Commonwealth Government was inaugurated, control by Americans, or by the United States Government, of health and welfare activities ceased. The public health nursing work described in this article represents the latest and the final move made by the former government to advance the cause of public health and welfare in the Islands.

Manila is a city of approximately 350,000 inhabitants. It is an oriental community in which the wealthier people maintain a standard of living similar to that prevailing among the same class in occidental countries, but where the poorer class lives on a standard but little if any above that obtaining for similar groups in other oriental cities.

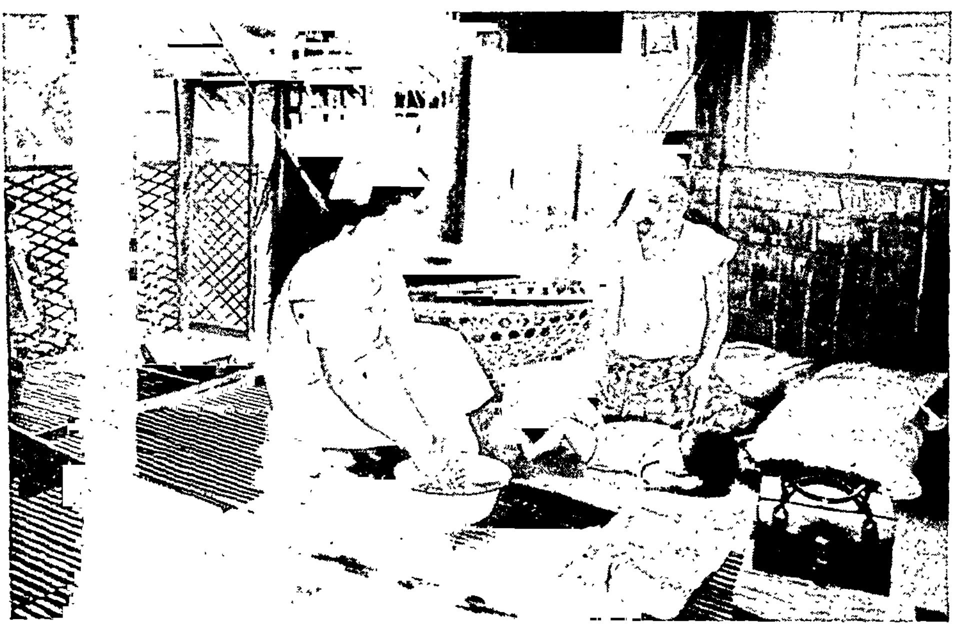
The average family living in Manila must have a family income of at least 30 pesos ($15 gold) per month in order to maintain the minimum normal standard of living. While no census has been taken, it is estimated that at least 10,000 families living in Manila have a family income of less than 30 pesos a month and that of these families at least 6,000 have a family income of not more than 15 pesos ($7.50 gold) a month. As in all cities, the families having an abnormally low standard of living have been crowded into the less desirable portions of the city where they live in a slum environment and under adverse social conditions.

Prior to 1934, no public health

* Technical Adviser on Public Health to the Governor-General, Philippine Islands until November, 1935.

A nurse visiting a home in Tondo slums

nursing service was available for the slum population of Manila, and there was no other agency by which instruction in health matters could be given to these people in their own homes. Consequently, but little if any progress was being made in the control of such diseases as tuberculosis, malnutrition, or intestinal parasitism. As only very meager facilities were available for the promotion of maternal and child health work among the members



A nurse showing a mother how to care for a sick child in a typical native home. The bamboo platform is the bed. Note the swinging bamboo cradle.

of this group, the infant mortality rate remained high, with no prospect of its being reduced.

The Bureau of Health of the Philippine Government has maintained a public health nursing service for a number of years, but prior to 1933 the bureau was so organized that such service was entirely inadequate. However, a reorganization of the health and welfare activities of the government which became effective on January 1, 1933, made it possible for public health nursing service of the bureau to be extended and coördinated with the other activities of the bureau. Following the reorganization, studies and surveys were made which showed that under the conditions existing in Manila a combined public health nursing service and social service offered the most feasible method of solving the public health problem discussed above. Consequently, the Bureau of Health developed a program of public health nursing and social service to meet the urgent need for health work in the homes of the poor people living in the congested districts of the city.

The fundamental principles of public health nursing are, of course, the same in Manila as they are in occidental countries, but the methods employed in applying these principles are modified by the local environmental factors and customs. The climate is tropical. The great majority of the houses of the poorer class are nipa huts, constructed of bamboo and roofed with nipa—the so-called light material houses. A smaller group of this class of the population live in stone, brick, or wooden houses, usually known as strong material houses.

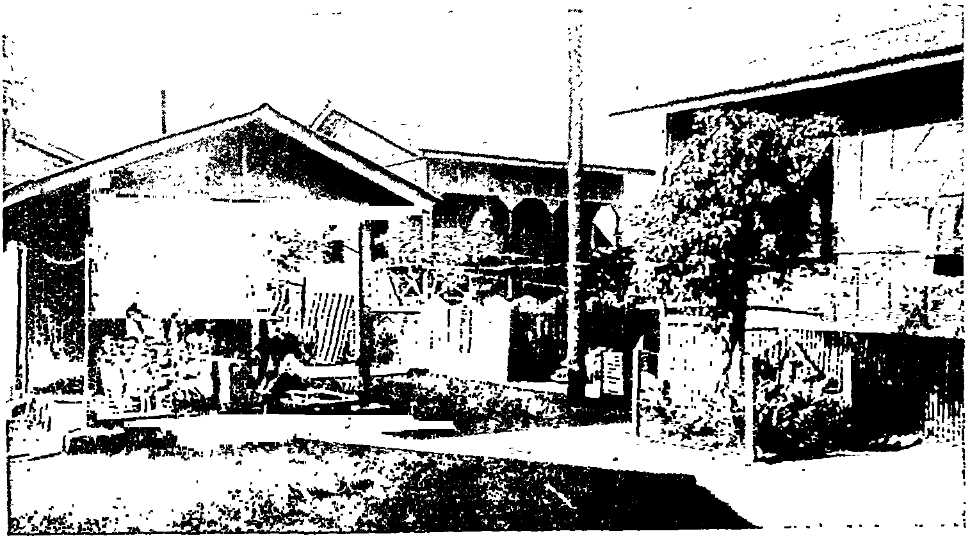
The dietary customs of the people constitute a serious health problem. The poor people subsist mainly on rice and fish with an inadequate quantity of fresh vegetables or fruits. Moreover, rice and fish are the preferred articles of diet, and the exclusion of other foods from the diet is frequently due to custom, and not entirely to poverty. Because of the defective diet, conditions due directly or indirectly to malnutrition are prevalent, particularly infantile beriberi and a lowered resistance to tuberculosis and other infectious diseases.

Family ties are strong among the Filipino people, and in many instances the family group is enlarged by relatives other than the immediate members of the family. The result is that the nipa huts, or the rooms of the strong material buildings, are crowded, with the consequent adverse health and social effects.

Because of the climatic conditions and poverty a large proportion of the children, and the adults as well, of the poor families do not wear shoes, or do so only at intervals. Consequently, infestation with hookworm is prevalent. Also, the customs which govern the preparation and handling of the food result in a high rate of infestation with ascaris. Surveys show that about 85 to 90 per cent of the population are infested with hookworm or ascaris, or both.

In order to meet this situation, community health centers were established in the affected districts, known as community health-social centers. The community health-social center, as it is conducted in Manila, is an agency designed to provide a combined health and social service, with the family as the unit served. The nursing and social service personnel consists of nurses trained in public health nursing and in social work. The clinics are conducted by physicians, each of whom has had special training in the particular work concerned.

Each center is composed of 4 basic sections, with such additional activities as may be required by local conditions. These sections are: social rehabilitation,



1. Model houses, part of the housing project in connection with Tondo Community-Social Center. 2. Nurse visiting a home of nipa construction. 3. Nurse visiting a home on Manila waterfront. 4. A corner in the Tondo slums.

child and maternal health, tuberculosis, and the general dispensary. A dental service is also provided for each center.

The basic functions of a community health-social center are the operation of clinics at the center and a home visiting service. There is a general clinic for the treatment of all kinds of cases; postnatal and prenatal clinics; a tuberculosis clinic; clinics for infants, and well baby clinics. These are held daily or at scheduled intervals. All service is free.

Home visiting by nurses is considered to be the most important activity of a community health-social center, because the fundamental function of the center is to carry health and social services into the homes of the people. The clinics conducted at the center are secondary in importance to home visiting.

In the operation of the home visiting services, the quality rather than the volume of the work performed is emphasized. This must be so if good results are to be obtained under the prevailing conditions. Follow-up work is essential to success and the nurse must visit a home many times in order to obtain the desired results. Ignorance is rife and many conditions favorable to the spread of disease prevail in the homes. Customs inimical to health must be changed. Finally, the mother rules the Filipino family in all matters that pertain to the home, and the mother must be taught in her own home how to protect the health of her family.

In order to insure that the home visiting work will be effective, the district served by a center is limited geographically to that which can be covered efficiently by the nurses available. Each nurse is assigned to a zone within this district and she is responsible for the home visiting work within that zone. The case load for a nurse is limited to the number of families which can be served effectively under the local conditions—usually an average of 10 home visits per day. The nurses do not make visits outside the geographical limits of the center districts. Experience has shown that when this is permitted the quality of the service rendered deteriorates.

Patients and personnel at the San Nicolas Community Health-Social Center

The centers are also utilized for the dissemination of instruction in health matters to groups, especially to mothers. Group instruction in prenatal and postnatal care and in the care of infants is given to pregnant women by trained workers. Cooking classes are held at regular intervals where practical instruction is given not only in cooking, but also in other phases of nutrition. Training in simple sewing is also provided for mothers. Reading and writing are taught to illiterate adults. Kindergarten classes are provided for the children of poor families as a means of attracting the parents to the center and obtaining their coöperation.

In 1934 sufficient funds were obtained from various sources for the operation of two community health-social centers. One was located in the Tondo and the other in the San Nicolas slum districts of the city. These centers were more or less experi-

mental in nature, particular attention being given to the development of procedures and technics adapted to local conditions. The success attained by these two centers during 1934 induced the Legislature to include the sum of $45,000 (90,000 pesos) in the budget of the Insular government for the operation of community health-social centers during 1935. A like sum has since been appropriated in the insular budget for 1936. The appropriation of funds as budgetary items instead of by a special act means that the appropriating authorities recognize that the work is a permanent activity and that it should be continued from year to year in the future. With the additional funds two other community health-social centers were established in the congested districts of Manila in 1935—making four in all. The new centers were located in the Santa Cruz and the Sampaloc slums.

The normal duty staff of each of the centers, as they are now organized, consists of 3 full-time physicians, 1 half-time physician who is a specialist in tuberculosis, 10 nurses, and the necessary attendants. One of the physicians serves as chief of the center, and 1 of the nurses as chief nurse. There is also the chief of the centers who is a physician trained in public health and sociology and who supervises the technical and administrative activities of all the centers in order to secure uniformity of procedure and coördination of all activities. He is assisted by a chief nurse for all the centers.

The objective of the work of the community health-social center is to effect the health and social rehabilitation of the family. Among the poor people of the Philippines the margin between destitution and a degree of prosperity which will permit the family to have a normal standard of living is so narrow that health work cannot be separated from social service. Frequently, in order to effect improvement in the health of a family, it is necessary to rehabilitate the family economically and socially. Material relief in the form of food or money may be required. It may be necessary to obtain better housing conditions, or to find employment for a member of the family. If this is not done the health measures which might be undertaken will have but little effect. Under these conditions, health work and social service must go hand in hand and the family as a whole, not the individual member of the family, must be regarded as the case.

The Tondo community health-social center is also a training center for nurses who are to be assigned to public health nursing work in other centers or in the provinces. The training consists largely of practical field work in public health nursing and social work. The center is provided with additional personnel for this purpose.

Table I shows in summary form the work that has been done by the community health-social centers in Manila during the 9 months, January 1, 1935, to September 30, 1935.

The work of the community health-

TABLE I

WORK PERFORMED BY THE FOUR COMMUNITY HEALTH-SOCIAL CENTERS IN MANILA DURING THE PERIOD OF JANUARY 1, 1935, TO SEPTEMBER 30, 1935

	Tondo	*San Nicolas*	*Sta. Cruz*	*Sampaloc*	*Total*
Number of families registered	4,073	3,474	3,527	3,417	14,491
Number of visits to homes	11,223	10,129	10,279	8,890	40,551
Number of individuals attending the center clinics	40,134	26,317	29,008	24,082	119,501

social centers in Manila has also influenced the development of a public health nursing service in the provinces. The Legislature appropriated the sum of $85,000 (170,000) pesos) for this activity in 1935 and a like sum for 1936. These appropriations were also made as budgetary items, and it is probable that they will be continued in the future. Public health nurses have been sent to 149 of the more backward barrios (villages) in the provinces and in addition 26 supervising nurses have been assigned to supervise and guide the barrio nurses. This work has been started only during 1935.

Antityphoid Inoculation

". . . During the Great War antityphoid inoculation by the subcutaneous route was a proved success; the incidence of enteric fever amongst the inoculated was little, whereas the uninoculated suffered severely. Oral vaccination against typhoid fever is now having a considerable vogue and yielding in some areas a more or less satisfactory experience. It is too soon to compare the relative values of oral and of subcutaneous methods of antienteric vaccination, because the former has not had the extensive field trials of the latter. Whatever value oral immunization may ultimately be proved to have, it is certain that 'subcutaneous inoculation has a definite methodical advantage, *i.e.*, dosage; in attempted oral immunization imperfect absorption of the antigen from the alimentary canal must occur frequently.

"I have encountered typhoid fever in persons 'immunized' comparatively recently with Besredka's typhoid pills *per os*. On the other hand, during the Dardanelles campaign I saw practically no true typhoid fever although there was every opportunity for its spread. The troops in the area had been inoculated in 1915 with antityphoid vaccine only, and not with triple (T.A.B.) vaccine, which fact accounted for the comparatively high incidence of paratyphoid fevers and the absence of typhoid fever itself. In 1916, when we returned to Egypt from Dardanelles, T.A.B. vaccine became generally available to us. Subcutaneous injection of this triple vaccine had the effect of eliminating almost entirely both typhoid and paratyphoid fevers. . . ."—William Campbell, B.Sc. (Public Health), M.B., Ch.B., F.R.S. Some Public Health Aspects of Immunity. *J. Roy. San. Inst.*, June, 1936, p. 815.

Lead Pipes as a Source of Lead in Drinking Water

G. N. QUAM AND ARTHUR KLEIN *
Chemistry Laboratories, Long Island University, Brooklyn, N. Y.

THE literature is quite replete with reports of lead poisoning, and not the least common source is water. In some instances the occurrence of lead poisoning from water has been so extensive as to be spoken of as an epidemic. The reported occurrences seem to be most numerous for Europe, and in the United States for the New England states. It is common knowledge that the use of lead pipes in connecting the mains to the domestic pipe lines is a usual practice. Furthermore we are aware of the fact that in some communities, many domestic service pipe lines are of lead throughout.

It seems entirely plausible that the sporadic cases of lead poisoning, and possible illnesses that are not diagnosed and recorded at all, may be due to a number of circumstances connected with lead service pipes. If water is permitted to remain at rest in a lead pipe, the quantity of lead dissolved is definitely increased—the time allowed may be only over night, a week end, a week, or it may be months. In any event, does the occupant of a dwelling, deliberately and methodically flush the line to the extent that practically all the excess dissolved lead is removed before a drink is drawn? If such precaution is not taken, it seems entirely possible that that portion of water standing in the lead pipe, even though it be only the connecting link between main and domestic line, may just reach the faucet in time to empty into a drinking glass.

In this investigation, an attempt has been made to simulate the actual conditions extant in our water supply systems. Samples of water have been permitted to remain in contact with lead pipes for varying periods of time, much as would be the case if the occupant of a dwelling were absent and upon his return would remove the water, perhaps for drinking.

EXPERIMENTAL

The methods of analysis adopted by the authors were: (a) the titrimetric extraction with diphenylthiocarbazone,[1] and (b) the colorimetric method based on the use of diphenylthiocarbazone.[2]

The lead pipes in which water was placed for known periods of time were 1¼" inside diameter and of composition and treatment specified by the Department of Water Supply, Gas and Electricity of the City of New York. The pipes were cut to 5′ lengths for convenience in handling, and were equipped with rubber stoppers and an escape vent to avoid trapped air in the test water. The capacity of each was 1,670 c.c. Before each pipe was used it was scrubbed with soap solution containing powdered pumice and thoroughly rinsed. Throughout the tests the pipes

TABLE I

CHARACTER AND SOURCE OF WATER SAMPLES

Sample	Source	Hardness [2]	Alkalinity [2]	Domestic Pipe Line
A	I	21	10	Steel
B	I	21	10	Lead
C	[1] I & II (mixed)	Ave. 37	Ave. 16	Steel
D	[1] III & IV "	Ave. 302	Ave. 160	Brass
E	V	417	30.7	Steel
F	I	21	10	Lead

1. C is a mixture of soft waters of low alkalinity; D of hard waters of relatively high alkalinity.
2. Data reported by the Department of Water Supply, Gas and Electricity of the City of New York.

were kept filled with water and never permitted to dry during the removal of samples.

The sources of water samples collected in the City of New York are here identified as Catskill (I), Long Island (II), Flatbush well No. 16 (III), Flatbush well No. 20 (IV), and Flatbush well No. 30 (V). In order that each sample may be more specifically identified, the condition of the domestic pipe line is also recorded in Table I. Each sample is from an active pipe line and the specimen taken for treatment and analysis represents water that might have been drawn for drinking purposes.

Part of each sample of water was concentrated (2 liters to 500 c.c.) and analyzed for its lead content as received from the faucet at the source. Table II shows these results.

TABLE II

ANALYSIS OF WATER AS RECEIVED, EXPRESSED AS MG. OF LEAD PER LITER (AVERAGE OF FIVE OR MORE SAMPLES)

A	B	C	D	E	F
0.025	0.15	0.028	0.068	0.071	0.135

TABLE III

ANALYSIS OF WATER EXPOSED TO LEAD IN LEAD PIPES FOR DEFINITE PERIODS OF TIME

Sample	Pipe No.	Date Drawn	Days Exposed	Mg. Pb. per Liter
A	1	1- 4-36	7	1.050
A	1	1-11-36	7	1.346
A	2	1-11-36	7	2.220
A	1	1-28-36	7	1.317
A	2	1-28-36	7	1.465
A	1	1-25-36	14	2.160
A	2	1-25-36	14	2.247
B	1	11-12-35	11	0.656
B	1	12-10-35	18	0.901
B	2	12-10-35	18	0.953
C	1	11-11-35	7	1.412
C	2	12-28-35	7	1.315
D	1	12-10-35	7	1.100
D	2	12-10-35	7	0.903
E	1	12-17-35	8	1.293
E	2	12-17-35	8	1.369
A	3	1-18-36	7	3.378
A	4	1-18-36	7	3.670
A	3	1-25-36	14	4.420
A	4	1-25-36	14	4.722

Water from source F was not subjected to the lead pipe treatment because of inconvenience in securing samples.

The remainder of each sample was exposed to lead of lead pipes for a known period of time at room temperature and then removed for analysis. Table III displays these results. Each pipe was refilled immediately after the sample was removed. The samples are identified by the letters A to F as in Tables I and II and are reported as mg. lead per liter in the water exposed to lead in a 5′ pipe of 1.67 liters capacity.

With the exception of the last four observations, the pipes used had been exposed to water for at least 60 days before the observations reported in Table III were made. Water exposed to lead in new lead pipes dissolved comparatively great quantities of lead. A sample (A) withdrawn from a new pipe at the end of the first 20 days contained 73.75 mg. per liter. Another sample (A) withdrawn at the end of 38 days' exposure in a second new pipe contained 66.40 mg. lead per liter.

The last four observations in Table III were made with new pipes which had been exposed to three changes of water for 7 day periods each.

The U. S. Public Health Service states that lead in natural water "shall not exceed 0.1 p.p.m."[3] Samples B and F, Table II, exceeded that limit for the particular samples analyzed. Of particular interest is the fact that Waters A and B are from the same source (Catskill) but B came through an all lead domestic service pipe system, while A came through steel pipes. Table III indicates the conditions that might develop if the service pipes were not in active use for the periods indicated and 5′ or more of lead pipe constituted part of the pipe line. Continuous flow, agitation, and diffusion all tend to prevent the development of such situations. The observations reported here make it appear quite obvious that domestic service pipe lines made entirely or even in part, of lead should be thoroughly flushed after a period of rest before the water is used for drinking or for cooking of foods.

Sixtieth Anniversary of American Chemical Society

CHARLES EDWARD MUNROE, eighty-seven years old, who all his life has worked among explosives, is the sole surviving charter member of the American Chemical Society, which at a national meeting in Pittsburgh, September 7–11, will celebrate the sixtieth anniversary of its founding.

The American Chemical Society, largest professional organization of its kind in the world, was organized in New York April 20, 1876. John W. Draper was the first president. Dr. Munroe was one of the original 183 members.

Three other members, J. B. F. Herreshoff, William H. Nichols, and H. E. Niese, maintained an unbroken connection with the American Chemical Society for more than fifty years.

Integrated Control of Occupational Diseases*

C. O. SAPPINGTON, M.D., Dr.P.H., F.A.P.H.A.
Consulting Industrial Hygienist, Chicago, Ill.

SURELY no proof is needed for the establishment of the socio-economic importance of occupational diseases, at least for those who have been reliably informed of our recent experiences.

It is also axiomatic that control and prevention are far superior to cure, viewed from any of the aspects concerning occupational disease problems.

Others have covered the medical and engineering control of occupational diseases. What I shall attempt to do, therefore, will be to bring together and integrate these methods of control—mention some of the technical difficulties which have arisen, consider practical applications of methods in the different groups interested, speak briefly concerning the evolution of control, and, finally, attempt to come to some rational conclusions and recommendations.

CONTROL METHODS

In considering the *engineering control methods,* we are concerned, (A) with the basic principle of first investigating occupational conditions; (B) measuring the severity of the hazard scientifically, then assessing the hazard; and (C) instituting the indicated measures which have been evolved. These control methods include: (1) a physical and hygienic survey of plant conditions; (2) occupational history and analysis of employees; (3) adequate information concerning the materials and processes used: (4) atmospheric and gross sampling of materials, associated with quantitative physical and chemical determinations; (5) the rating of the hazard by comparing the findings in a given instance with accepted criteria; (6) an assessment of the efficiency of protective apparatus and devices; and (7) an adequate and proper interpretation of this information, so that it can be practically applied to the industrial problem involved.

If the above procedures give information which indicates the necessity of using various methods of protection, the following have been found useful in different combinations: (1) the use of mechanical devices, such as exhaust ventilating systems, respirators, masks, or helmets; (2) the changing of processes; (3) the substitution of non-toxic materials for those of proved toxicity; (4) educational programs; and (5) the continued maintenance and checking of the efficiency of protective equipment.

It is not claimed that the above list is exhaustive; there may be other measures of equal importance, but it is believed that the principal ones have been mentioned, and it is also known that they have been used successfully.

The *medical methods of control* are

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

likewise well known, but will be mentioned briefly: (1) preëmployment physical examinations, with which is associated a thorough occupational history going back if possible for a period of 10 years; (2) periodic examinations of employees in so far as this is possible, but especially in instances where known hazards exist; (3) laboratory examinations, both in preëmployment and periodic examinations, to obtain evidence supplementary to physical examinations, and to determine whether the applicant or employee shows signs of the effects of occupational exposure; (4) educational programs, constantly acquainting employee and employer with the need for the use of medical control procedures; and finally (5) continuous and careful medical supervision, involving the principles of employee-placement and adjustment, as well as continued study of environmental conditions and the proper functioning of protective mechanisms.

It will be seen that the object of engineering measures, simply stated, is to estimate the severity and nature of the hazard presented and to recommend the use of methods in the industrial environment to control such hazard, while the object of medical procedures is to determine the nature and extent of the effects of the environment on the bodies of the exposed employees and, similarly, to recommend and institute measures for control and prevention.

TECHNICAL DIFFICULTIES

Although it will not be possible to discuss all the technical difficulties, emphasis will be placed upon the lack of proper coördination or integration of engineering and medical methods of control and the results thereof. It often happens, for instance, that the assessment of hazards in industrial environment is interpreted entirely separately from medical findings on employees in that environment. Contrariwise, it more frequently occurs that the medical data constitute the sole evidence upon which judgment is made as to the existence of potential occupational disease hazards.

The fallacy here is evident, because occupational disease is the direct result of exposure to deleterious conditions, materials, or processes found in an industrial environment. There is, therefore, a distinct cause-and-effect relationship, which cannot be efficiently used unless the interpretation of this cause-and-effect relationship is made by a thoroughly qualified person who understands the evaluation of an occupational disease hazard in terms of its effects upon the human body.

We cannot expect that the engineer will be able to do diagnostic work—nor should he be expected to understand the application of the fundamental principles of industrial toxicology—although in some instances he may be able to tell what will probably take place under certain conditions; likewise, in most instances, the industrial physician, who has had little training in or contact with the engineering principles of industrial hygiene, will not fully appreciate the importance of the environment as an etiological factor in the production of occupational diseases.

We thus have a condition in which the engineer is interested in his side of the work, chiefly the industrial environment, and the physician, largely with diagnostic problems. The result has been a lack of real coördination and integration of causal factors with physiological functions of exposed employees.

This lack of integration has been because of the scarcity of what we might call "qualified interpreters" who understand and appreciate the principles involved on both sides of this question and are able to make inter-

pretations in simple terms, so that this combined information may be issued to, and used by manufacturers, insurance companies, attorneys, and others to whom it is of vital concern.

The physician-industrial hygienist is probably the one specialized type of person who can adequately take the responsibility for this situation. Unfortunately, few of these have been developed, and in order to make usable the information gained by application of the methods of control of occupational diseases, we cannot depend entirely upon those few who have fortunately been able to secure training both in the fundamentals of medicine and industrial hygiene.

It is obvious that we cannot expect engineers to become physicians; it does seem reasonable, however, to expect the industrial physician to superimpose upon his medical background and experience at least an appreciation and working knowledge of the principles of industrial hygiene to the end that he may be in a position to integrate intelligently the etiologic and pathologic factors concerned in occupational diseases. Certainly, the majority of occupational disease problems which come up for final decision are medical in aspect, and it seems rational to say that the physician must, in the final analysis, take the responsibility for these decisions. Examples of the smooth functioning of such a principle are to be found in the work of the Office of Industrial Hygiene and Sanitation, U. S. Public Health Service, and the Bureau of Occupational Diseases, State Department of Health of Connecticut, where the technical and administrative policies of the group are under the guidance and control of an experienced medical officer.

As Glenn Frank has so well stated:

> The future of America is in the hands of two men—the investigator and the interpreter. We shall never lack for the administrator, the third man needed to complete this trinity of social servants. And we have an ample supply of investigators, but there is a shortage of readable and responsible interpreters, men who can effectively play mediator between specialist and layman. The practical value of every social invention or material discovery depends upon its being adequately interpreted to the masses. Science owes its effective ministry as much to the interpretative mind as to the creative mind. The knowledge of mankind is advanced by the investigator, but the investigator is not always the best interpreter of his discovery. Rarely, in fact, do the genius for exploration and the genius for exposition meet in the same mind. . . . The investigator advances knowledge. The interpreter advances progress. History affords abundant evidence that civilization has advanced in direct ratio to the efficiency with which the thought of the thinkers has been translated into the language of the workers.

It has seemed to me that the regular routine physical examination must undergo considerable adjustment before it can be properly applied to occupational disease potentialities, both in the routine examination before employment and during employment on hazardous jobs. The physician surely should have in mind those conditions and defects which may become aggravated by the specific exposure which the employee meets. The physical examination should always be interpreted in the light of the possible effects of industrial environment. In other words, the physician should take into account particularly the nature and severity of the hazard presented, in evaluating the defects or abnormal conditions found on physical examination This would appear to be a more intelligent application of the industrial physical examination than has been widely and generally made.

To apply these principles successfully, the examining physician should be able to give an intelligent answer to the following questions: (1) Do you know the nature and severity of the

occupational hazard into which the examinee is going? (2) Are you satisfied that the examinee does not possess any abnormal conditions or defects which might be aggravated by occupational exposure? (3) Do you know the nature of the protective devices which are provided for the use of the employee and whether such devices are known to function properly?

Through intelligent interpretative comments in the answer to these questions, the physician can serve industry much more efficiently than he usually has done in the past.

PRACTICAL APPLICATION OF METHODS

In applying the principles of coordination and integration to the more efficient use of information regarding the control of occupational diseases, we are confronted with the problems of manufacturers, insurance companies, attorneys, and industrial commissions. We cannot entirely separate the problems of legal and compensation aspects from those of prevention and control, for we learn preventive methods largely through the so-called "trial-and-error" system. What we know about preventive medicine, for instance, was largely gained through repeated and collected experiences concerning disease manifestations and the ways in which they have been contracted. This principle applies no less to the prevention and control of occupational diseases, and it is necessary that preventive methods be developed through continuous observation and study of the avenues through which they develop; in other words, in our time at least, it will be impossible to divorce the study of the occurrence and effects of occupational diseases from that of their prevention, if advancement is to be accomplished.

It means practically nothing to the manufacturer to tell him that he has air in which there are 50 million dust particles per cu. ft.; that the free silica content of this dust amounts to 35 per cent; and that a particle-distribution study shows the majority of the particles to be below 3 μ in greatest diameter. Nor does it do him much good to find out that he has, in certain processes, a lead-in-air content of 10 mg. per 10 cu. m. of air, or a concentration of 1,500 p.p.m. of carbon monoxide. What the manufacturer wishes to know is the significance of these figures and what they mean in terms of possible disability among his employees. Someone must explain these things to him promptly and plainly.

Insurance company representatives, including engineers, claim men and underwriters, ask the same questions. The engineers want to know just what exposure would be safe. The underwriting group wants to know whether Plant A, as surveyed, is a good risk to put upon the books.

Attorneys and members of industrial commissions desire to know whether a given set of industrial conditions is an actual occupational disease hazard, whether the employee actually has the occupational disease in question, and whether such disease was contracted in the plant where the employee recently worked.

All of these are definite, practical problems regarding the etiology of occupational disease and its manifestations. If we can so assemble our information that we come to reliable conclusions and make these available, industrial medicine and hygiene will have performed a signal social and scientific service.

Clearly, the rational basis for intelligent underwriting and compensation for occupational diseases lies in obtaining over a period of many years, adequate and continued records of industrial exposure and its effects in producing disease and disability. This may

take considerable time, effort, and patience.

EVOLUTION OF CONTROL MEASURES

It is my belief that we are in an evolutionary period regarding occupational diseases. If we look back on our experience with fires, we find a prototype of this evolutionary process. In the beginning, there was no fire insurance and great losses were suffered. Eventually a system was provided by which one could insure against fire and the losses resulting. People discovered that in many cases it was not possible to recover the total loss suffered. After years of this experience, someone developed the idea that fire prevention was less costly than expecting to recover losses through insurance, although it was advisable both to carry coverage and prevent fires. Today we have developed many methods for the prevention of fire, as well as having improved in our ways of fighting fires. We can draw a similar analogy between the evolutionary processes of occupational diseases and those of accidental injuries. Time was (and probably still is, in some quarters) when those in authority believed that the effects of accidental injuries may be fully covered by insurance. This conception has gradually given way to the principle of accident prevention, which, while not fully developed, has gone a long way.

We shall probably have to learn the same lessons in occupational diseases that have previously been taught to us regarding fires and accidental injuries. Prevention is by far the most economical procedure, viewed from any angle.

CONCLUSIONS AND RECOMMENDATIONS

We may conclude that there is great need for more extensive use of the principle of integration in associating information and coming to more reliable conclusions regarding the causes and effects of occupational disease—such results to be applied in their prevention and control.

Such action would involve the training and employment of greater numbers of those whom we have been pleased to call "qualified interpreters," or, a combination of the following: (1) the use of consultants and advisers by manufacturers in working out their problems of occupational disease prevention and control; (2) adaptation of available personnel to the work of insurance companies, in respect to industrial investigations, claims problems, and the underwriting of future risks; (3) the development of more scientific medico legal principles in the handling of legal and compensation problems; (4) the further enlightenment and training of engineers, physicians, insurance company representatives, attorneys, industrialists, industrial commissions, and associates, through periodic conferences, meetings, and lectures.

If I have appeared to be presumptuous and have trod upon traditions and disturbed old trains of thought, we can take courage from the words of Henry Thomas Buckle:

> For the great enemy of knowledge is not error, but inertness. All that we want is discussion and then we are sure to do well no matter what our blunders may be. One error conflicts with another, each destroys its opponent, and truth is evolved. This is the course of the human mind, and it is from this point of view that the authors of new ideas, the proposers of new contrivances, and, the originators of new heresies, are the benefactors of their species. Whether they are right or wrong is the least part of the question. They tend to excite the mind; they open up new faculties; they stimulate us to fresh inquiry; they place old subjects under new aspects; they disturb the public sloth; and they interrupt rudely, but with most salutary effects, that love of routine which, by inducing men to go groveling on in the ways of their ancestors, stands in the path of every improvement, as a constant, and outlying, and too often, a fatal obstacle.

Detailed Study on Diphtheria Immunization*

With the One Dose Alum Precipitated Toxoid

H. H. PANSING, M.D., AND E. R. SHAFFER, M.D., F.A.P.H.A.

Health Commissioner of Montgomery County, Dayton, Ohio; and Former Associate of the State Department of Health, Columbus, Ohio

THIS study was made on 3 separate groups of school children, primarily of the first 3 grades, and was for the purpose of determining the efficacy and permanency of immunization against diphtheria by means of a single dose of 1 c.c. alum precipitated toxoid. It was conducted by individuals having had extensive experience in this work since the inception of active diphtheria control measures in Ohio. The toxoid used was from regular lots passed and approved by the National Institute of Health, Washington. Schick test control was not used, inasmuch as the Schick material was a non-peptone base, and 5 days elapsed between test and interpretation of reactions.

The discussion of Groups A and B in considerable detail has already been reported by Dr. Pansing.[1] The reader is referred to this publication for details pertaining to this study.

Group A—This group of 527 children was given the original Schick test September 13, 1933. On September 18, 1933, 468 were found to be Schick positive and were given 1 dose of 1 c.c. alum precipitated toxoid. On October 16, 1933, or 28 days after the toxoid was given, 462 of these children were retested with the following results: 388, or 84 per cent, were Schick negative, and 74, or 16 per cent, were Schick positive. Carrying through our original group the 74 who were Schick positive were retested for the third time at the end of 60 days to determine if there was any increase in the number rendered Schick negative after the 28 day period. This showed that only 7 children had changed from positive to negative Schick reaction at the end of 60 days.

Group B—This group of 570 children was entirely new, from different schools, and was given the original Schick test January 23, 1934. On January 29, 1934, 495 were found to be Schick positive and were given 1 dose of 1 c.c. alum precipitated toxoid. This second study was for the purpose of confirming the technic and results obtained on Group A. On April 4, 1934, or approximately 60 days after injection, 445 of those receiving treatment were retested, with the following results: 363, or 86 per cent, were found to be Schick negative, and 82, or 14 per cent, were Schick positive. It was found in some schools that as high as 96.5 per cent, and in others as low as 79 per cent, were rendered Schick negative on the 60th day after inoculation.

Group C—Those children who were

* September 13, 1933–December 4, 1936.

recorded as being Schick negative from both Groups A and B comprised the final group study, which represents only those children who were recognized to be positively Schick negative 2 years prior to the time of conducting the Group C study.

It is desired to emphasize the fact that Group C, on which the final study was made, consisted of children all of whom were Schick negative 28 or 60 days following 1 dose of 1 c.c. alum precipitated toxoid. It is shown in this final study that 57.8 per cent of a group of 549 Schick positive children who showed Schick negative 28 or 60 days following administration of 1 dose of 1 c.c. alum precipitated toxoid, reverted to Schick positive after 2 years. This surely is conclusive evidence that the early protection effected by a single dose of 1 c.c. alum precipitated toxoid is not of sufficient permanency to justify the continued use of a single dose as the method of choice in diphtheria control.

Attention is directed to information gained from this study, which indicates that a somewhat more permanent protection is secured in those children receiving the second dose of 1 c.c. alum precipitated toxoid. It will be noted that this group showed that 60 per cent retained immunity compared with 42.2 per cent retained by the group having only 1 dose. However, this small group consisted of children who were never Schick negative, as far as this study is concerned, and may include children who are recognized to be resistant to any antigen.

TABULATION OF GROUP C

This comprises a final group of 549 children who were initially Schick positive, given 1 dose of 1 c.c. alum precipitated toxoid, retested on the 28th or 60th day and found to be Schick negative, and retested 2 years later December 4–6, 1935.

The group receiving the second dose of 1 c.c. alum precipitated toxoid 60 days after the first dose is quite small. However, it confirms the theory that

secondary stimulus is required to produce sufficient antitoxin in the blood stream to effect more lasting immunity. If this be true, as we believe, multiple doses of alum precipitate or unmodified toxoid are indicated. This study was undertaken primarily for the purpose of determining the degree and permanency of the immunity from a single dose of alum precipitated toxoid. Our findings confirm in this respect the report of Fraser and Halpern, University of Toronto, Canada,[2] who show by blood serum titrations in a group of children, that the antitoxin response "to 3 doses of unmodified toxoid is distinctly better than the response to 1 dose of alum precipitated toxoid." These titrations were made before injection and 10 weeks, and 1 year after injection, with the following results:

	Units Antitoxin 10 Weeks	*Units Antitoxin 1 Year*
1 dose A. P. toxoid	62% more than 1/100	19% more than 1/100
	30% more that 1/50	11% more than 1/50
3 doses plain toxoid	91% more than 1/100	91% more than 1/100
	91% more than 1/50	69% more than 1/50

SUMMARY AND CONCLUSIONS

1. Analysis of the data from the initial study of Groups A and B indicates early and high immunity from 1 dose of 1 c.c. alum precipitated toxoid on the 28th and 60th day after inoculation, as determined by Schick test.

2. Analysis of the data of Group C comprising a group of 549 children who were Schick negative 60 days after administration of 1 dose of alum precipitated toxoid, indicates that 57.8 per cent have lost this protection at the end of 2 years.

3. The group of children receiving a second dose of alum precipitated toxoid indicates somewhat higher percentage of immunity at the end of the 2 years. It is recognized that this group was extremely small. However, 60 per cent were Schick negative compared with 42.2 per cent for the group receiving a single dose.

4. The benefit derived from secondary stimulus by means of multiple injections of antigen is indicated.

5. These data confirm the belief that efforts to simplify the technic to a single dose antigen led to the sacrifice of reasonable permanency of immunity for greater convenience of administration.

6. From this study we hope to stimulate further laboratory and clinical research in order to determine on a plan of more permanent protection against diphtheria.

Government Lands

AT a recent meeting of the American Title Association, Memphis, it was reported that the government now owns more than 400,000,000 acres of land. In the last fiscal year public domain increased 2,850,000 acres. For the present fiscal year acquisition of more than 10,000,000 acres is planned.

Response to Rabies Vaccine Prophylaxis as Shown by Protection Tests*

JOHN REICHEL, V.M.D., F.A.P.H.A., AND J. E. SCHNEIDER
Mulford Biological Laboratories, Sharp & Dohme, Glenolden, Pa.

TWO years ago we reported on Rabies Vaccine Protection Tests [1] and detailed the intralingual method of the injection of the infective dose of rabies virus into rabbits and the advantages of the method and test.

We have continued with the test on rabbits on the basis that rabies vaccine prophylaxis should actually protect the animal against an infective dose of rabies virus, which in the amount of 0.1 c.c. of a 5 per cent fresh brain tissue emulsion from a rabbit dead of fixed rabies virus, injected intralingually or directly into the tongue, should prove fatal for at least two-thirds of the control rabbits. Such injections usually result in a fatal infection in more than two-thirds of the control rabbits and not infrequently in all of the controls with a period of incubation and death in 8 to 9 days as against 6 to 7 days when the same dose of fixed rabies virus is injected intracranially.

The group 1 rabbits died in 9 days, and all of the group 5 rabbits survived the initial infective dose. The death of 1 rabbit of the 6 in group 4 not only indicates the infectivity of the 0.0001 c.c. dose, but also the effect on the period of incubation and death, which in this instance was lengthened to 16 days. The 0.01 c.c. dose proved infective for 5 of the 6 group 2 rabbits, and 2 of these showed a lengthening of the period of incubation and death to 10 days. Group 3 rabbits with the 0.001 c.c. infective dose showed an increased period of incubation and death of 10–14 days in the 4 of the 6 rabbits in which the dose proved fatal.

The rabbits that survived the original infective dose were held for 24 days and then injected intralingually with a 0.1 c.c. dose of a 5 per cent brain tissue suspension of fixed rabies virus, identical with the dose originally employed on the group 1 rabbits of which there were no survivals. The second infective dose injections had no apparent effect on the 1 surviving rabbit of group 2, and the 2 rabbits of group 3, which may indicate natural resistance to all of the injections of these rabbits or increased resistance from the first injection which enabled these rabbits to withstand the second infective dose. The group 4 rabbits are of special interest in that at least sufficient rabies virus was included in the 0.0001 c.c. dose to infect 1 of the 6. The remaining 5 rabbits on the second infective dose showed natural susceptibility in 3, with death in 8 to 9 days, while 2 survived. The second infective dose on the group 5 rabbits killed 5, or over two-thirds, which is the usual occurrence in control groups of rabbits. The results

§ 0.5% Brain tissue emulsion rabies virus, 0.1 c.c. injected intracranially

of the Table I data support the deduction that the simultaneous use of dilutions of fixed rabies virus, injected intralingually is accompanied by a lengthening of the period of incubation.

The groups 1 to 7 rabbits all received the same rabies vaccine phenol killed in 0.5 c.c. daily doses for 7 days, injected subcutaneously. The infective dose for each group was injected intralingually with a time interval of 1 day for group 1 to 21 days for group 7. The results indicate that as short an interval as 3 days is followed by an increased resistance. Of the 20 rabbits injected with daily 0.5 c.c. doses of rabies vaccine phenol killed, 17 survived the infective dose, and 3 died irrespective of the different intervals, while of the 21 control rabbits injected intralingually with the infective dose only 5 survived and 16 died, and of the 21 control rabbits injected intracranially with the infective dose 1 survived and 20 died.

Groups 1 to 7 rabbits were injected subcutaneously with 25 per cent *normal* rabbit brain and cord tissue phenolized emulsion in 0.5 c.c. daily doses, so that the results could be compared with the results of the protection tests of Table II. Of the 20 rabbits included in groups 1 to 7 in Table III, only 3 survived, and 17 died following the intralingual injection of the infective dose, showing that *normal* rabbit brain and cord tissue emulsion did not increase the resistance of the rabbits, and that the rabbits were as susceptible as the control rabbits, of which 21 injected intralingually 5 survived and 16 died, while of the 21 control rabbits injected intracranially 1 survived and 20 died.

Groups 1 to 10 rabbits were injected subcutaneously with 0.5 c.c. doses of rabies vaccine phenol killed and group 1 to 7 injected intralingually with the infective dose without an interval between the last dose of vaccine and infective dose. None of the rabbits developed an increased resistance. Groups 8, 9 and 10 injected with 7 daily doses of vaccine followed by an interval of 1, 2 and 3 days, had an increased resistance to the infective dose. Of the 30 control rabbits injected intralingually with the infective

dose of fixed rabies virus, 6 survived and 24 died, and of the 30 control rabbits injected intracranially 2 survived and 28 died.

Groups 1 to 5 rabbits were injected subcutaneously with a single dose of rabies vaccine, phenol killed, and after an interval of 14 days each rabbit was injected intralingually with the infective dose.

Inasmuch as 2 of the 3 group 1 rabbits injected with 1.25 c.c. single dose of vaccine died and all 3 of the group 2 rabbits injected with 2.5 c.c. single dose of vaccine died, the doses of vaccine injected failed to increase the resistance of the rabbits to the infective dose. The single doses of vaccine injected into groups 3, 4, and 5 rabbits apparently increased the resistance of these rabbits to the infective dose. The death of 1 rabbit in groups 3 and 5 suggests that the 3.75 c.c. dose of group 3 and the 6.25 c.c. dose of group 5 were less efficient than the 5 c.c. dose of group 4.

The data in Table V show that sufficient vaccine must be included in the single dose to show increased resistance to the infective dose after a 14 day interval. There is also some indication that there are limits to the proper dose and that too much vaccine may not increase the resistance of rabbits to the infective dose after a 14 day interval any more than too little vaccine in the single dose.

CONCLUSIONS

Fresh fixed rabies virus in the form of a 5 per cent brain tissue suspension in 0.1 c.c. doses injected intralingually can be relied upon as an infective dose, and to produce rabies in rabbits with an incubation period and death in from 8 to 9 days. It has been shown that dilutions of the virus so injected, are accompanied by an increase in the period of incubation, and that it is possible to inject a dilution which is capable of infecting only a small percentage of the rabbits, and the rabbits that do develop rabies in the higher dilutions will have a lengthened period of incubation.

In the protection tests described, phenol killed rabies vaccine was administered under various dosage schemes and intervals before the injection of the infective dose. These tests show that it is possible to increase the resistance of rabbits injected with rabies vaccine phenol killed, and then exposed to the infective dose, while rabbits prophylactically treated with normal rabbit brain tissue emulsion show no increased resistance to the infective dose of fixed rabies virus.

It seems necessary to employ the proper amount of rabies vaccine in the single dose prophylactic treatment to increase the resistance of rabbits to an infective dose after a 14 day interval.

Incidence and Behavior of Non-Lactose Fermenting Bacteria from Normal Stools

RUTH M. KRIEBEL
Harvard University School of Public Health, Boston, Mass.

IN 1934 the author[1] described a number of strains of Gram-negative, non-lactose fermenting bacteria isolated from the stools of 25 out of a group of 127 healthy food handlers, during a routine search for intestinal pathogens. Six additional groups, totaling 384 food handlers, have now been examined, and similar bacteria, resembling the Salmonella but failing in one respect or another to fit in that group, have been isolated from 84 stools. This paper presents data on the incidence of these organisms, evidence through lactose fermentation of their relationship to the colon group, a description of the dissociation of colon strains into non-lactose fermenting variants, and a report of the quantitative utilization of lactose by the non-lactose fermenting bacteria.

The procedure followed in isolating the cultures has already been described[1]: first platings from stools on eosin-methylene-blue agar and transfer of colorless colonies to Russell's double sugar agar slants. All cultures were tested for fermentation of carbohydrates, the production of indol, the Voges-Proskauer and methyl-red reactions, the utilization of citrate as sole source of carbon, the liquefaction of gelatin, and agglutination in specific diagnostic sera.

INCIDENCE

Table I lists the number of food handlers examined in each group and the number of non-lactose fermenting strains isolated. Two facts are evident from this table: (1) Non-lactose fermenting bacteria were encountered

TABLE I

INCIDENCE OF NON-LACTOSE FERMENTING BACTERIA IN NORMAL STOOLS

every year and in each group of food handlers, although no carriers of intestinal pathogens were found. (2) The incidence of these strains generally decreases through the winter months, the incidence being highest in October and decreasing through December and January. This fact was demonstrated indirectly in an earlier report [1] which described the examination of 21 food handlers whose stools all had contained these organisms in November; when recultured in March only 3 stools contained them. The data suggest a seasonal variation with highest incidence in the late summer months. The institutions employing these food handlers are closed during the summer and an examination of the subjects is impossible until fall.

There was also a variation in individuals from year to year, shown when the stools of 102 food handlers (in Groups A-1 and A-2, Table I) were cultured in 2 successive years. It was found that these bacteria were neither constantly present nor culturally identical in any individual. The stools of 19 subjects contained these bacteria in 1933, though they had been negative the year before; the stools of 13 were negative in 1933 though they had been positive the year before; the stools of only 8 contained these organisms both years, and they were not biologically identical. Eighty stools were negative both years.

In a study of Lactose Degraded Colon-Aerogenes Organisms in Normal Feces, Parr [2] found that such organisms were rare in fresh feces, but increased to about 17 per cent in stored feces. He later demonstrated [3] that this increase was caused by a change in ordinarily normal colon organisms. Confirmation of the fact that such changes can occur in colon bacteria will be given later, but aging or storage of the specimens does not account for the high percentage of the strains described here. Great care was taken in timing the collection of specimen tubes so that the stools could be plated within a very short time after passage. No specimens were shipped nor were preservatives used.

LACTOSE FERMENTATION

Following the method outlined in an earlier paper,[1] all the original non-lactose fermenting cultures were incubated in 5 per cent lactose-peptone-water with Andrade indicator, for 2 weeks. Those cultures which produced any fermentation were transferred to 1 per cent lactose, in series, until fermentation occurred daily. These cultures were then plated on eosin-methylene-blue agar, and their ability to use lactose in a solid medium was noted. Table II, using the same groups as Table I, shows that an average of 55 per cent of the originally non-lactose fermenting strains finally fermented lactose, and that an average of 56 per cent of these acquired a completely colon type of reaction on eosin-methylene-blue agar. Once acquired, the ability to ferment lactose has been permanent. The cultures really fall into two groups, the "slow lactose fermenters," which give a delayed reaction and half of which assume all the characters of true colon bacteria,* and the true "non-lactose fermenters," which never ferment this sugar. The colonies of the slow lactose fermenters, in pure culture on eosin-methylene-blue agar, are large, opaque, and faintly colored, in contrast to the colonies of the non-lactose fermenters which are small, gray and transparent.

---

* The term "true colon bacteria" is used here in a broad sense to include aerobic, Gram-negative, nonspore forming bacilli, fermenting lactose with acid and gas in the standard liquid and solid differential media, and producing the characteristic color and metallic sheen on eosin-methylene-blue agar.

DISSOCIATION OF COLON CULTURES INTO NON-LACTOSE FERMENTERS

A striking example of the loss of power to attack lactose was furnished by a number of strains of *Escherichia coli*. A large group of strains (120) of true colon bacteria * had been isolated from the stools of the food handlers in Group A-2, and were stored on extract slants. Several months after isolation, these cultures were again plated on eosin-methylene-blue agar. Colorless colonies were observed in 19 of the cultures. Although the colon cultures were purified twice, the non-lactose fermenting colonies invariably appeared after the cultures had aged 2 or more weeks on the slants. Single cell isolations of 13 of the dissociating cultures were then made by fishing from dilute suspensions on agar with the aid of a micromanipulator. These single cell cultures had true colon reactions when first isolated, but non-lactose fermenting colonies appeared in all of them when they had aged on the slants for a few weeks. Except for the reaction to lactose, all the variants were identical with the parent strains. When grown in .5 per cent lactose, one of the variants fermented it weakly, but the rest were true non-lactose fermenters, and this character has been permanent. Since the variants arose unquestionably from unmixed colon strains, strong support is furnished for the view that such strains appearing in normal stools can also be variants of true colon bacteria.

An attempt was made to produce this change in colon bacteria by a controlled experiment. Fifteen colon cultures were grown for 4 months at room temperature in 3 different media: a saline suspension of sterile feces, 10 per cent ox bile, and extract broth. No variants appeared in any of the cultures. It is evident that neither feces nor pure bile had a retarding influence, in the test tube at least, on the ability of these cultures to ferment lactose. Five of the strains were originally slow lactose fermenters, which had acquired a completely colon type of reaction. The remainder of the cultures were 3 Aerobacter, 1 Citrobacter, and 6 Escherichia.

The effect of a strong colon bacteriophage,* acting for several weeks on a group of colon strains, was also studied. Rough colonies appeared among the resistant forms which grew out after lysis, but no change was observed in regard to lactose fermentation. The fact that colon variants may show colony differences but no alteration in the fermentation of sugars has also been observed by Bergstrand,[4] Lewis,[5] Gratia,[6, 7] and others. In a control group of cultures which were not attacked by this phage, a few strains produced non-lactose fermenting colonies after several weeks. However, these appeared also in the broth tubes containing no phage, and are therefore clearly not the result of bacteriophage action, but are simply another example

* The term "true colon bacteria" is used here in a broad sense to include aerobic, Gram-negative, nonspore forming bacilli, fermenting lactose with acid and gas in the standard liquid and solid differential media, and producing the characteristic color and metallic sheen on eosin-methylene-blue agar.

* I am indebted to Dr. Roy Feemster for the use of all the bacteriophages employed in the tests described here.

of the susceptibility of certain cultures to the effects of aging.

The dissociation of these colon strains into non-lactose fermenting bacteria has remained an unexplained phenomenon, and no light has been thrown on the nature of the change by our attempts to produce similar effects through the action of feces, bile, or bacteriophage. Parr[3] observed that this type of change is more easily effected by these methods in the Aerobacter group than in the Escherichia group. All the variants reported here however, arose from the Escherichia type.

UTILIZATION OF LACTOSE

Jones, Orcutt, and Little[8] have described a group of non-lactose fermenting bacteria which they isolated from the feces of cows with infectious diarrhea. Continuous incubation in lactose broth resulted in fermentation in varying periods of time. When they determined quantitatively the amount of lactose consumed by 5 of these cultures, they found that the sugar was utilized from the beginning in as large amounts as colon strains used, but that the pH was high and this alkalinity was masking the fermentation for some days.

To see if a similar condition was true of the organisms reported here, a group of slow lactose fermenters and non-lactose fermenters was selected and grown in 1 per cent lactose-peptone-water. Neither salt nor indicator was added, and the medium was sterilized by filtration through a Berkfeld N filter to avoid any hydrolysis of the sugar in autoclaving. The lactose consumed was determined by the method adapted for bacterial cultures by Stiles, Peterson, and Fred[9] from Shaffer and Hartmann's[10] volumetric method. Analyses were made after 2 and 6 days' growth at 38° C., that is, before and after fermentation was expected. Before each analysis, Andrade indicator was added to a portion of the culture to demonstrate the usual acid reaction, if present. The exact pH was also determined colorimetrically. Considerable difficulty was experienced with the method, and the error was large; averages of the results were nevertheless consistent. Ten strains of slow lactose fermenters consumed as much lactose as 4 colon strains (0.3–0.6 mg.), but not until the customary acid production was evident with Andrade indicator, and not until the pH had fallen to 5.0 or lower. Seven strains of non-lactose fermenters and 2 strains of *Salmonella paratyphosus* B consumed no lactose, or very small amounts which could be attributed to error in analysis (—0.052 to +0.053 mg.). They also showed no change in pH and remained colorless when Andrade indicator was added. In short, the result of these determinations showed that the utilization of lactose by these cultures was accurately shown by the usual fermentation tests.

CLASSIFICATION

The cultures described here consisted of morphologically short, Gram-negative bacteria, almost coccoid in form in contrast to the longer bacillary form of the usual colon bacteria. They all produced gas in the carbohydrates fermented. All fermented some sugars in addition to dextrose, so were not Morgan's bacillus. None liquefied gelatin in 2 weeks' growth. None of the colonies developed lactose fermenting papillae in several days' growth on plates; so they could not be considered as *B. coli mutabile*, described by Neisser[11] and recently by Dulaney and Michelson.[12]

Attempts to classify these non-lactose fermenting and slow lactose fermenting strains by agglutination in specific diagnostic sera were futile. Antisera (Mul-

ford's) for 2 Escherichia types, 4 Salmonella, 3 Dysenteriae and *E. typhosus* were used diluted and undiluted against suspensions of all the organisms. Over 65 per cent of the strains were entirely negative, and the positive ones agglutinated nonspecifically in the entire range of sera, and in low dilutions only. A group of 15 strains of colon bacteria reacted in exactly the same way.

Further attempts to classify these strains by the action upon them of a large number of coli, dysentery, and typhoid bacteriophages also failed. Very few of the strains were susceptible to lysis. Those which were attacked by the phages were not affected specifically.

The cultural reactions of these bacteria, however, place them surely in the colon group. The 60 strains of slow lactose fermenters may thus be considered as colon bacteria. Of the 49 strains of non-lactose fermenters, 26 fermented sucrose, or formed indol or did both, and may also be grouped with the colon bacteria, on this basis. The remaining 23 strains of non-lactose fermenting bacteria did not form indol or ferment sucrose, but may also be classed with the colon group for this reason: 8 strains of indol negative sucrose negative *Escherichia coli* were isolated, and 2 of these strains produced non-lactose fermenting variants identical with them except for the lactose reaction, as already described. Therefore it is obvious that cultures identical with the Salmonella in all respects except agglutination, can arise from true colon strains.

If then these cultures are all regarded as members of the colon group, it is possible to classify them in established groupings by the Voges-Proskauer and methyl-red reactions, indol production and citrate utilization. Following the groupings of Werkman and Gillen,[13] Levine,[14] and Kline,[15] these 109 cultures can be grouped as 74 strains of Escherichia, 14 strains of Citrobacter, and 21 strains of Aerobacter. Eleven of these were the "intermediate" types described by Kline,[15] Tittsler and Sandholzer,[16] Koser,[17] and others. That is, they varied from the type in the Voges-Proskauer or methyl-red reaction, or in indol production or utilization of citrate. All the strains in the Escherichia group could be classified on the basis of sucrose and salicin fermentation by the simplified method of Levine [14] into the 4 common varieties.

CONCLUSION

Although the organisms reported here were isolated from healthy people, it must be remembered that most of this type of organism described in the literature have been isolated from cases of diarrhea, sometimes in epidemic form. The accumulation of evidence showing the presence of these bacteria during intestinal derangements cannot be disregarded simply by classifying them in the colon group. It is significant that the fermentation of lactose, which has provided the chief routine distinction between the pathogenic and non-pathogenic intestinal forms, should be the reaction most subject to fluctuation. The frequency with which these lactose aberrant colon bacteria are encountered in intestinal disturbances suggests that the loss of power to ferment lactose may be related to a possible transition state between the non-pathogenic colon group and the pathogenic Salmonella.

SUMMARY

1. Non-lactose fermenting bacteria have been isolated from stools of 109 healthy people in routine stool examinations of 511 food handlers of several schools.

2. These strains were encountered in each group examined.

3. A seasonal variation was observed, with highest incidence near the summer months, and decreasing through the winter.

4. Repeated examinations showed that these organisms were not constantly present in any individual, nor did constant types occur in one person.

5. Over half of the organisms were finally able to ferment lactose, and over half of these acquired a completely colon type of fermentation on solid media.

6. Dissociation of 19 strains of *Escherichia coli*, 13 strains of which were single cell cultures, into permanently non-lactose fermenting variants, is described.

7. Neither the action of a strong coli bacteriophage, nor growth in sterile feces and in 10 per cent bile, produced non-lactose fermenting colonies in colon strains.

8. Quantitative determinations of the amount of lactose consumed by a group of these cultures showed that lactose was not utilized until acid production was apparent by the usual tests.

9. Classification of the cultures by agglutination in diagnostic sera, and by the action of bacteriophage, was impossible.

10. However, classification by cultural reactions was possible, and all the strains were shown to belong to one type or another in the colon group.

11. Although it is a simple matter to classify these organisms in the colon group by careful attention to all the aspects of lactose fermentation, it is suggested that the frequent reports of their presence in intestinal disturbances may indicate a transition state between the non-pathogenic and the pathogenic types.

Improvised Clinic

WITH the nearest hospital 30 miles away, the little community on Grand Isle in Lake Champlain needed a medical center desperately. So Dr. and Mrs. Frank Hall decided in 1933 to convert an unoccupied house into a clinic.

Substituting energy for capital, they rescued old "double-deckers" which a nearby camp was discarding and converted them into hospital beds. They contrived bedding from anything that could be sewn together and made pillows from discarded pieces of oilcloth. The operating table was built by the local carpenter for one dollar. Out of the kitchen came Mrs. Hall's roaster, promoted to the rank of sterilizer. The community helped. Local women became nurses; others made bandages.

Patients pay for services according to their means, sometimes in cash (as little as 50 cents for an operation), sometimes in produce. One man is paying for his baby in perch at 15 cents a dozen.—*Readers Digest*, February, 1936, p. 109.

Incidence and Significance of Beta Hemolytic Streptococci in Cultures from a Selected Group of Milk Handlers*

FRANKLIN M. FOOTE, M.D., DR.P.H.; HENRY WELCH, PH.D.; D. EVELYN WEST; AND EARLE K. BORMAN

Department of Public Health, Yale University School of Medicine, New Haven; and the Bureau of Laboratories, Connecticut State Department of Health, Hartford, Conn.

THE subject of laboratory examinations of milk handlers as an integral part of a program for the control of milk-borne disease has been reviewed by West, Borman, and Mickle [1] and Borman, West and Mickle.[2] In the publication of the former the results of experience in Connecticut with a state-wide program of this type were discussed. This paper prompted the formulation of a questionnaire regarding the value of the Connecticut program and of all such examinations in general, which was submitted to persons considered qualified to express authoritative opinions. The replies to this questionnaire formed the basis for a general discussion of the subject presented in the latter paper. One point in particular was so obviously controversial that no satsifactory conclusion could be drawn from the many opinions expressed; *i.e.*, the value of examinations of throat and nose cultures for beta hemolytic streptococci.

Prompted by the paramount importance of streptococcus infections in the history of milk-borne disease, Borman, West, and Mickle [2] made the following recommendation in formulating a rational milk-handler control program:

> Examinations of throat and nose cultures for beta hemolytic streptococci should be incorporated as soon as reliable and practicable methods for determining the virulence or invasive power of any given strain are developed. In the absence of a satisfactory criterion it may be desirable in some areas to regard any milk handler as dangerous when he is harboring large numbers of typical beta hemolytic streptococci.

The necessity for examining this recommendation in the light of a controlled experiment to determine its feasibility was apparent. The study now to be presented and discussed was designed to throw light on the following points: (1) the efficiency of routine methods, practicable in a centrally located public health laboratory, for detecting the presence of beta hemolytic streptococci in throat and nose cultures; (2) the incidence of positive cultures in a representative group of milk handlers under normal conditions; (3) the extent of association of positive cultures with significant clinical find-

---

* Based in part on a dissertation submitted by the senior author, while a Commonwealth Fund Fellow, to the Faculty of Yale University in partial fulfillment of the requirements for the degree of Doctor of Public Health. Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

ings; (4) the characteristics and probable significance of the strains isolated.

PLAN OF THE STUDY

Permission was secured from the managers of 5 dairies to take weekly throat and nose cultures of their 85 employees. The dairies were selected to include distributors both of raw and of pasteurized milk. Although it was realized that cultures taken more frequently would probably throw more light on the intermittency of the carrier state, practical considerations made more frequent culturings not only inadvisable—lest the coöperation of the subjects be lost—but physically impossible, since the time spent by the physician doing the field work in addition to a portion of the laboratory work was limited by other duties. Weekly cultures, however, were considered much more satisfactory from this standpoint than the monthly, semi-annual, or annual cultures required in Connecticut for handlers of certified, Grade A raw and pasteurized milk respectively. The number of men cultured each week varied somewhat since a few men would necessarily be taking their "day off" on the day of each visit. Nine of the 85 subjects could be cultured only 3 times or less. No attempt was made to explore the tonsillar crypts since we wished to simulate conditions under which routine cultures are taken by physicians examining milk handlers in Connecticut.

Symptoms of acute rhinitis, tonsillitis, and pharyngitis or other significant clinical findings were noted when the swabs were taken.

In order to determine the effect of drying and other factors associated with delay, duplicate swabbings were made of both the throat and the nose of each man cultured. One swab was used for making "immediate" cultures by the senior author; the other was sent by parcel post to the Bureau of Laboratories in Hartford simulating conditions under which milk handler cultures had been handled since the inception of the Connecticut program described in the publication[1] previously cited. All "immediate" cultures were made not later than 1½ hours after obtaining the swabbings; the majority within 1 hour. The swabs sent through the mails were cultured about 18 hours after collection. The first swabbings obtained were used for "immediate" culturing one week, and for "delayed" culturing the following week. This was carried out serially throughout the study.

"Immediate" plate cultures were made by surface inoculation on both sheep blood agar and on neopeptone-Savita rabbit blood agar.* The order of streaking plates was alternated each week; *i.e.,* sheep blood agar first one week, rabbit blood agar first the following week, and so on in rotation. One-half of each plate was used for streaking the throat specimen, the other half for the nose specimen, from one individual. The surface method of inoculation was chosen because of difficulties which make the use of pour plates impracticable in a central laboratory where specimens arrive for plating at any time of the day or night. Furthermore, since further studies of the strains isolated were planned, detailed observation of sub-surface colonies was not felt necessary.

During the first 3 weeks of the study swabbings for "delayed" culture were inoculated onto moist Loeffler's blood serum slants in the field, and both slants and swabs were then sent through the mails. The slants were subsequently sub-cultured on sheep blood agar for beta hemolytic streptococci. "Delayed" cultures from the swabs were made only on the sheep blood agar in a manner identical with

* The cost of materials for this medium was defrayed by a grant from the Research Fund of the School of Medicine of Yale University.

that employed in making "immediate" cultures. In addition, during 3 weeks of the study the swabs were cultured in dextrose broth with subsequent plating on sheep blood agar.

Only cultures showing colonies or areas surrounded by a clear zone of beta type hemolysis caused by streptococci were considered positive. All positive cultures were studied after isolation in pure culture for morphological, biochemical and serological characteristics. Each strain was tested for final pH in dextrose broth,[3] hydrolysis of sodium hippurate,[4] effect upon methylene blue milk,[5] and fermentation of sorbitol and trehalose.[6] An extract containing the group-specific precipitinogen was prepared from each strain and tested against antisera for the serological groups A, B, C, and D of Lancefield.[7]

Strains obtained directly from Dr. Lancefield were used for the preparation of antisera. The technic of injecting rabbits was as follows: The group A antigen was prepared fresh daily by centrifugalizing a heat-killed broth culture of the strain representative of the group. The other group antigens were prepared by sedimenting broth cultures of the strains used and formolizing the sediment. Antisera were prepared by daily intravenous injections into rabbits over a period of 10–12 days. On the first day, 0.3 ml. of the sediment from 10 ml. of broth culture was injected. The dosage was gradually increased to 2.5 ml. of the sediment from 150 ml. of the respective broth cultures for the last injection. Sera of high precipitin titer could be prepared in 15 days by the use of this method. All sera prepared were checked for specificity. Reciprocal cross-reactions were obtained with the groups A and C antisera when tested against extracts of the strains used for antiserum preparation.

Extracts containing precipitinogens were prepared according to the technic described by Lancefield.[7] In making the precipitin tests, the respective antisera were layered under the extracts in Hektoen tubes by means of capillary pipettes. Readings were made after 2 hours at room temperature by observing ring formation in the zone between the layers. The contents of the tubes were then mixed and allowed to stand over night in the refrigerator before the final reading was made by observing precipitation in the bottoms of the tubes.

One observation * in connection with the fermentation tests is worthy of note here. Much more rapid and satisfactory results were obtained when the carbohydrates were incorporated in a nutrient broth base containing 0.05 per cent agar than when Hiss's serum water (prepared from human serum) was used. Fermentation of trehalose was often obtained in the former medium within 24 or 48 hours which occurred only after as long as eight or ten days, or not at all in the latter medium. The explanation for this probably involves the occurrence of a zone of the proper oxidation-reduction balance surrounding the particles of agar in colloidal suspension. Certainly it could not in this case be construed as due to the presence of a growth promoting nutritional factor in the broth containing agar. In every instance growth and acid production were first observed about 5–6 mm. below the surface where settling of the agar particles produced a shelf. The organisms appeared to grow at the interfaces formed by the particles and the broth in which they were suspended.

RESULTS OBTAINED

During the 13 week period of the study, 756 throat and 756 nose speci-

* We are indebted to Professor Charles A. Stuart, Department of Biology, Brown University, Providence, R. I., for the suggestion which led to this observation.

mens were obtained from the 85 milk handlers. The number of men cultured each week averaged 63 and none of them was cultured more than once during any one week.

The use of moist Loeffler's slants for primary field cultures proved of no value since not a single positive subculture out of 300 was obtained by this method, whereas 15 of these specimens yielded positive results on one or more of the three sets of primary cultures on blood agar plates. Similar results were experienced with the use of dextrose broth as an enrichment medium after swabbings had been transmitted through the mail. As a consequence, these two lines of investigation were discontinued.

Of the 1,512 sets of throat and nose cultures made, 85 (5.6 per cent) were positive for beta hemolytic streptococci by one or more of the three duplicate blood agar cultures. Of the 1,512 "immediate" cultures on the rabbit blood agar, 65 (4.3 per cent) were positive. "Immediate" cultures on sheep blood agar yielded 69 positive findings in a total of 1,512 (4.5 per cent). A significant decrease was noted with "delayed" cultures on sheep blood agar which gave 33 positive cultures out of 1,512, only 2.2 per cent.

Of the 756 culturings on 85 individuals (throat and nose cultures in each instance), 64 (8.5 per cent) were positive from one or both sources by "immediate" culture on the rabbit blood agar; 66 (8.7 per cent) by "immediate" culture on sheep blood agar; only 30 (4.0 per cent) by "delayed" culture on sheep blood agar. Of the "immediate" cultures made from the first of the duplicate swabbings taken, 10 per cent were positive as against 7 per cent with the second of the duplicate swabbings. However, the first swab yielded 3 per cent positive by "delayed" culture and the second 5 per cent. There appeared to be no difference between sheep blood agar and the rabbit blood agar for this type of work.

During the period of this study 20 (23.5 per cent) of the 85 men gave positive cultures for beta hemolytic streptococci at one time or another. Of the 65 giving negative cultures throughout, 8 were cultured less than 3 times in all.

Six of the 20 individuals found positive were detected only by "immediate" cultures; 1 was detected only by "delayed" cultures and this individual was positive only once.

A further analysis of the results brings out certain facts relating to the transiency of the carrier state. One individual was found positive in the only 3 weeks during which he could be cultured. The second and third positive cultures were obtained in this case in the 4th and 5th weeks following the first. Two individuals were positive in 3 out of 4 weeks cultured, with 1 intervening week negative. Four individuals were consistently positive; 1, 10 times in 10 weeks; 1, 10 in 11; 1, 11 in 12; 1, 12 in 12. One man was positive 6 times in 10 weeks, 5 of these times in successive weeks. Another individual cultured 11 times was positive for 2 consecutive weeks, with a third and final positive culture 4 weeks after the second. Five men were positive only twice out of 10 or more times cultured although not on successive weeks. In 3 of these instances the second positive culture was obtained 2 weeks after the first; in the other 2, 6 weeks after the first positive culture. Five individuals were positive only once. These 5 were cultured 6, 11, 11, 12, and 13 times respectively.

Some degree of statistical association between positive cultures and acute rhinitis was found, although this association was not great enough to indicate any practical value. By com-

parison, the statistical association between acute rhinitis and positive throat cultures was somewhat greater in this series. Perhaps this may have been due to the beta hemolytic streptococci present in deep tonsillar crypts emerging to the surface membranes under the influence of favorable environmental conditions following lowered host resistance, or to drainage into the throat from some focus not reached in swabbing the nose.

A statistically significant association was found between positive throat cultures and concurrent acute pharyngitis or tonsillitis. Thirteen of the positive cultures were associated with these conditions which were observed 22 times out of 756 observations. The association, however, was not close enough to be of practical value. The association between positive cultures and concurrent symptomatology in both throat and nose was greater.

The 5 individuals who showed positive cultures 6 or more times may be regarded as persistent carriers. One of these had a highly significant clinical history. He had been ill in bed for 17 days during the month before this study was begun, with a condition diagnosed as "quinsy sore throat." He later stated that he still had a sore throat when he returned to work. His tonsils were always slightly swollen and red with a small amount of purulent exudate on the surface. Cultures from this man were positive for beta hemolytic streptococci in every week of the study. One other persistent carrier usually complained of a "head cold," and once or twice of a "scratchy throat." His tonsils were small, clean, and apparently normal. The remainder seldom complained of symptoms although an acute rhinitis was found at least once in each case during the study. Two of them possessed small tonsils, normal in appearance. The third stated his tonsils had been removed during his childhood and that he never had had a sore throat. No tags of tonsillar tissue were observed in this man's throat.

The 15 individuals showing positive cultures once, twice, or three times during the study gave the following histories: 3 presented distorted, buried and hard tonsils showing occasionally an excess of debris in the crypts; 3 others had had their tonsils removed several years before and rarely suffered from pharyngitis; the remaining 9 had tonsils essentially normal in appearance. Seven of this group never showed any clinical findings of significance within the scope of the examination.

During the study 40 of the 85 men gave no significant clinical or laboratory findings although 5 of these were observed only 3 times or less. There were 25 individuals who showed symptoms of acute rhinitis, pharyngitis, or tonsillitis at one time or another without ever yielding a positive culture. Three of these were cultured less than 4 times. In this group of 25, acute rhinitis was by far the most common clinical feature.

The results of the biochemical and serological studies demonstrated but little difference between the several strains. Of 77 strains isolated in pure culture, 10 gave a final pH below 4.8 in dextrose broth. The lowest reading obtained was pH 4.2. None of the 77 cultures hydrolyzed sodium hippurate, and only 2 reduced methylene blue in milk cultures. All fermented trehalose but not sorbitol. All gave strong precipitin reactions with our group A antiserum. A slight cross-reaction was noted in the majority of instances with group C antiserum but in no instance with antisera for groups B and D. This cross-reaction was noticed particularly by the ring-test reading and often appeared less strong or disappeared altogether when the over night readings were made.

A number of strains isolated were subjected to tests to determine their fibrinolytic activity * against human fibrin, since studies by Tillett and Garner,[8] Dennis and Berberian[9] and Tillett[10] indicate that this property is closely associated with the virulence or invasive power of a strain. Of 14 strains from 14 individuals so tested, 9 produced fibrinolysis in from 3 to 45 minutes; 2 required 1 to 4 hours; 3 were either negative or required 10 to 12 hours.

DISCUSSION

One comparison serves to show that the milk handlers studied formed a representative group. In this study 4 per cent of throat and nose cultures (considered in combination) were positive from one or both sources by "delayed" culture. During this same period the percentage of positives found by routine state-wide milk handler examinations was 3 per cent. The "delayed" cultures in this study are in all respects comparable to the cultures formerly made routinely on milk handler specimens in Connecticut.

Despite the high carrier incidence found, no outbreaks occurred among consumers of milk from the dairies under study, perhaps because sufficiently large doses of the organisms did not reach the milk. Probably this situation would hold true in general until infection of a cow's udder by a milker or some gross contamination of the milk by other means occurred, since studies of the strains isolated failed to show any distinguishing characteristic which would separate them from known pathogenic varieties. None of the strains showed the mucoid characteristics which have been described for organisms associated with certain milk-borne outbreaks of septic sore throat, but in our practical experience non-mucoid varieties are often the etiological agents in milk-borne streptococcus infections. No attempt was made to determine the toxigenic properties of the strains since the invasive power of these organisms is not necessarily associated with ability to produce an exotoxin. Certain variations were observed in the fermentative action on dextrose of the strains as determined by final pH readings in broth cultures. These readings varied more widely with cultures isolated at different times from the same individual than with cultures from different persons. Two cultures reduced methylene blue but all other cultures from the same individuals failed to do this. Although extracts from many of the strains gave cross-reactions with Group C precipitin serum, the reactions obtained with group A antiserum were much stronger and very clear-cut. Furthermore, reciprocal cross-reactions of the same degree could be demonstrated with the sera used when tested against extracts of the stock strains obtained from Dr. Lancefield which were used for immunizing the rabbits. Therefore, reactions with group C antiserum were undoubtedly nonspecific and we were dealing with group A streptococci in every instance. This is further borne out by the failure of the strains to attack sodium hippurate and sorbitol and their ability to ferment trehalose.

The fibrinolytic studies suggest that a large majority of the strains were potential human pathogens since the studies of other workers[8, 9, 10] indicate a close association between the invasive power of strains of beta hemolytic streptococci and their lytic action on human fibrin.

It is of interest to note here that the beta hemolytic streptococci isolated by routine examinations of specimens from milk handlers throughout the state

---

* We are indebted to Dr. W. D. Tillett, Johns Hopkins Hospital, Baltimore, Md., whose kind offer to make these studies made it possible for us to secure these data.

while this study was in progress had the same general characteristics as those isolated from the selected group.

Our results clearly indicate that satisfactory means for controlling milk-borne streptococcus infections have yet to be devised. Although doubtless much can be accomplished by furthering the use of pasteurization by greater efforts to eliminate mastitis in dairy herds and by educational methods, no specific mode of attack seems adequate with our present knowledge.

CONCLUSIONS

1. Moist Loeffler's blood serum slants did not prove satisfactory as primary field cultures for detecting milk handlers who were harboring beta hemolytic streptococci in the throat or nose.

2. Sheep blood agar (pH 6.6–7.0) was as efficient as neopeptone-Savita-rabbit blood agar (pH 7.4–7.6) for the growth and detection of beta hemolytic streptococci.

3. Transportation of throat and nose swabbings through the mails resulted in a reduction of approximately 50 per cent in positive findings as determined by making controlled cultures (756 throat and 756 nose) in duplicate before and after transportation. The time elapsing between collection and plating after transportation was approximately 18 hours. Even enrichment cultures in broth after transportation were not so efficient as simple surface inoculation on blood agar; in fact, they were entirely unproductive.

4. Twenty (23.5 per cent) of 85 milk handlers in the representative group selected harbored beta hemolytic streptococci, in throat or nose secretions or both, at least once during the 3 months of the study as determined by weekly cultures. This occurred during January, February, and March, the months when the incidence of positive findings is at its peak in Connecticut.

5. Five of the 20 individuals showing positive cultures were persistent carriers of the organism throughout the study.

6. In the 756 observations made, the association between positive laboratory findings and such clinical symptoms as acute rhinitis, pharyngitis, and tonsillitis, while statistically significant, was not sufficiently close to be of practical value for control purposes.

7. Individuals without tonsils or remnants of tonsillar tissue may be persistent carriers of beta hemolytic streptococci in the absence of significant clinical findings.

8. Our results indicate that strains of beta hemolytic streptococci found in individuals in an average state of health are indistinguishable on the basis of biochemical and serological characteristics from strains of known pathogenicity for man. Assuming the lytic action of any strain on human fibrin to be associated with its invasive power, the majority of these strains are potential human pathogens.

9. With regard to the problem of milk-borne streptococcus infections and under climatic and other conditions similar to those under which this study was made, our results indicate that:

a. Physical examinations alone are not sufficient for the detection of all carriers of beta hemolytic streptococci.

b. Routine laboratory cultures are inadequate for the detection of all carriers, unless made more frequently than is practicable under ordinary administrative conditions.

c. Beta hemolytic streptococci do not withstand drying and other factors associated with delay in transportation to the laboratory sufficiently well for the detection of carriers in a central laboratory with any adequate degree of completeness.

d. Two types of carriers of these organisms, transient (or occasional) and persistent occur among milk handlers in an average state of health, and the organisms of this type carried are potentially pathogenic for man, should sufficient numbers find access to the milk.

e. The percentage of persons harboring these organisms is too large to permit adequate control of milk-borne streptococcus infections by employing any practical measures to eliminate the carriers.

f. Since the frequency of the carrier state seems to bear no close relationship to the frequency of milk-borne streptococcus infections, outbreaks probably occur only when a comparatively large inoculum of infecting organisms reaches the milk from an udder infected by a milker or, probably less often, from some other source.

g. Consumers must be protected against milk-borne streptococcus infections by other means than by periodic physical and laboratory examinations.

NOTE: The authors wish to express their appreciation to Betty Robinton for technical assistance.

Use of the Terms "Sterile," "Sterilize" and "Sterilization"

IN an official communication from the Food and Drug Administration of the U. S. Department of Agriculture, the Council on Pharmacy and Chemistry of the American Medical Association was asked to express an advisory opinion as to the use of the terms "sterile," "sterilize," and "sterilization," especially when it appears on the labels of agents used "for sterilization of the skin."

The Council adopted the following statement and authorized its transmission to the Food and Drug Administration:

The Council on Pharmacy and Chemistry has formally gone on record as disapproving the use of the terms "sterile," "sterilize," and "sterilization" in a bacteriologic sense other than in their correct scientific significance; *i.e.*, meaning the absence or destruction of all microörganisms. These terms are not relative and to permit their use in a relative sense not only is incorrect but opens the way to abuse and misunderstanding. It is questionable that there are any chemical agents tolerated by the skin which will produce sterility, although there are some which will reduce the bacterial flora of the skin to such an extent that they may properly be described as disinfecting agents. For such agents there is no objection to the use of the terms "disinfecting," "bactericidal," and "bacteriostatic."

Reference was also made to the decision of the Committee on Foods, which is as follows:

Use of Terms "Sterile," "Sterilized," and "Sterilization." The terms *sterile, sterilized* and *sterilization* shall be used in food advertising in their correct scientific significance only. Foods processed to be free of pathogenic organisms or to keep sound and wholesome are not necessarily sterile, *i.e.*, free from viable microörganisms.

Lumber Camp Inspections

ELMER W. CAMPBELL, D.P.H., F.A.P.H.A.
Director, Division of Sanitary Engineering, State Bureau of Health, Augusta, Me.

UNTIL very recently, Maine, in common with most lumbering states that have depended upon remoteness to make lumber camps safe, had given little attention to the sanitary inspection of them. The condition continued, not because the health authorities were remiss, but from a lack of both inspection personnel and legislative authority. In 1931, two relatively small outbreaks of typhoid occurred almost simultaneously at separate camps of the same operator. Indeed, although never so proved and although the camps were located on separate watersheds, their close proximity indicated that the two outbreaks were in effect only one.

The moving incidents are fairly typical of under-regulated lumber camps, wherever located. In Camp Number 1, an open privy was distant only 100 feet from the building where the crew ate. Swarms of flies had easy access to both places. In Camp Number 2, in addition to the same hazards, there was the insanitary situation of a privy built on the bank of a stream above the pool from which the camp water supply was drawn. In accordance with the practice of the Bureau of Health, men of both crews were immunized, and the hazards ordered abated. Parenthetically, one man who had been infected remained a carrier for more than 4 years.

The department, or more definitely the Division of Sanitary Engineering to which was charged the supervision of lumber camps, moved to start routine inspections. It had long been established that such camps, if under only desultory inspection, were excellent culture ground for filth diseases. Still worse, since workmen were drawn from widely separated homes, the breakup of the camps at the end of the working season made the camps the best possible focal points for spreading the disease.

The procedure and experience of the Division of Sanitary Engineering may be interesting. A program of education of lumber operators was plainly indicated. Accordingly, there was called a conference of the division, with representative operators from the membership of the Timber Land Owners' Association. The necessity of adequate camp sanitation and the responsibility of camp operators for the public health were studied and carefully discussed.

The good will gained by the contacts made at this conference still persists, simplifying greatly the work of subsequent supervision, for the committee chosen from among the operators took over the task of extending the good will throughout the whole number of their organization. In that manner, generally by word of mouth, was carried out a campaign of education.

Moreover, this committee with the division's engineers developed a set of regulations agreeable to both the department and the members of the Timber Land Owners' Association. Presented by the joint committee to the Advisory Council of the Bureau of Health and Welfare, the regulations

reached formal approval on December 5, 1933. The 20 sections of regulations which have the force of law, provide for proper location and camp layout, water supply and handling, disposal of wastes, proper toilet and washing facilities, screening, dishwashing, the supply, handling and refrigeration of foods and milk, precaution against spread of infections and vermin, the manner of abandoning camp, provision for a caretaker, fixing responsibility for carrying out the provisions and finally fixing a nominal fine for failure to adhere to the rules.

The Division of Sanitary Engineering considers the program begun in 1931 well justified. During the year in which the Rules and Regulations became law, inspectors visited 143 camps which employed 4,647 men. Five typhoid carriers were found, either as cooks or cook's helpers, called cookees. These people were removed from camp, and typhoid immunization recommended. As a result, nearly 1,000 employees received anti-typhoid inoculations.

In the following year, the inspections showed that of the same number of camps with 5,184 employees, 86 had made substantial improvements in sanitary conditions.

The Division of Communicable Diseases of the Bureau of Health reports that no cases of typhoid fever have been traced to lumber camps since the enactment of definite regulations and the inauguration of routine inspections.

Birth Certificate

EIGHT-YEAR old Agnes was frequently sent home from school for forgetting to bring written excuses for tardiness or absence from classes. One day she was sent home to bring an important document, the birth certificate of her little brother Billy, who was just starting to go to school. Her mother handed her the certificate and cautioned her to take good care of the precious paper.

Agnes turned up at school crying.

"What's the matter now?" asked the teacher.

"I've lost Billy's excuse for being born!" she wailed.

Immediate Allergic Response Following a Schick Test

ALVIN E. KELLER, AND SEALE HARRIS, JR.
Department of Preventive Medicine and Public Health; and the Department of Medicine, Vanderbilt University School of Medicine, Nashville, Tenn.

AN immediate allergic reaction following a Schick test in individuals who have been immunized against diphtheria is unusual. Recently Harrison [1] called attention to the fact that McGinnis * observed a number of reactions of the immediate type in children who were given a Schick test 8 weeks after receiving an injection of alum precipitated diphtheria toxoid. To one of these individuals it was necessary to give an injection of adrenalin. This report deals with 2 reactions of this type in persons who were given a Schick test some time following immunization with alum precipitated diphtheria toxoid.

The first instance was in a graduate nurse who in 1925 received 3 doses of toxin-antitoxin without a preliminary Schick test. In 1927 a negative Schick test was reported. In 1931 she was employed in Vanderbilt Hospital and a routine Schick test resulted in a "combined reaction." No immunization was attempted at that time. During the years 1932 and 1933 this nurse was either not employed in the institution or was away from work on account of illness. In September, 1934, she returned to work and another Schick test was done with a questionable "positive reaction." On November 19, 1934, the Shick test was repeated and a "positive reaction" was obtained. On December 5, 1934, one subcutaneous injection of 0.5 c.c. of alum precipitated diphtheria toxoid was given after a toxoid skin test was found to be negative. On January 2, 1935, a Schick test was negative. In a routine check-up of all nursing personnel who had received diphtheria immunization during the previous year another Schick test was done on this individual on May 23, 1935. With each of these Schick tests control tests were made in the opposite arm with heated diphtheria toxin.

From 15 to 30 minutes following the Schick test on May 23, 1935, the patient developed marked local reactions at the sites of injection. In some respects these were similar to the immediate reactions described by Neill, Fleming, and Gaspari [2] following the intracutaneous injections of diphtheria culture filtrates. The edema in the arm into which unheated diphtheria toxin was injected was perhaps somewhat more marked than in the arm receiving heated toxin. Shortness of breath, swelling of the face and eyelids, together with itching and urticaria over the upper part of the chest followed immediately. The patient was given a subcutaneous injection of adrenalin and the shortness of breath, itching, and urticaria slowly subsided. The edema at the sites of injection of

* Personal communication to Harrison, 1935.

the heated and unheated diphtheria toxin disappeared more slowly than did the itching, edema, and urticaria over the face and chest.

The second reaction of this type was encountered in a medical student who in November, 1934, was found to have a positive Schick test. A control test with heated diphtheria toxin at that time was negative. A toxoid skin test was performed a few days later and was found to be negative also. This student was given 0.5 c.c. of alum precipitated diphtheria toxoid subcutaneously on December 5, 1934. Four weeks later another Schick test was performed. It was positive and a control test with heated toxin was negative. In order to determine whether or not a dosage of 0.5 c.c. was sufficient to immunize, no further injections of alum precipitated toxoid were made. A Schick test 8 weeks after the single injection of alum precipitated toxoid was negative. To determine whether or not the immunity which had developed was lasting another Schick test was made on May 22, 1935. It was negative.

In October, 1935, 10 months after the single injection of alum precipitated diphtheria toxoid, this individual received a Schick test and a control test with heated diphtheria toxin. Within 10 minutes after the injections it was noted that a marked immediate local reaction developed at the sites of injection similar to those observed in our first case. Immediately following the development of the local reaction the patient developed dizziness, suffusion of the eyes, and became very uncomfortable. The reactions at the sites of injection increased in size and edema developed over these areas. Burning and itching of the feet and of the upper part of the chest and axillae then developed. A few small urticarial lesions developed over the arms. Following a subcutaneous injection of adrenalin the symptoms subsided slowly and after about an hour and a half the urticaria and the itching had practically disappeared although the patient still complained of feeling uncomfortable. A scattered urticarial eruption reappeared on the arms a few hours later. These disappeared, however, after the oral administration of ephedrine sulphate and no further symptoms were noted.

In the other patient no further reaction occurred after the immediate allergic reaction subsided. In each individual both the tests with the heated and unheated diphtheria toxin were negative after 4 days.

These 2 instances of hypersensitiveness, apparently induced by immunization with alum precipitated diphtheria toxoid are the first in our experience. Since neither of the individuals exhibited reactions to the heated toxin before immunization, and since the manifestations of hypersensitiveness followed retesting after a subcutaneous injection of alum precipitated toxoid, it seems probable that these patients became sensitized as a result of the immunization with the alum precipitated toxoid. A similar experience with alum precipitated toxoid has been observed by McGinnis. It seems not unreasonable to predict an increasing incidence of such reactions in the future as a result of the more extensive use of alum precipitated toxoid in diphtheria immunization. This should be borne in mind when individuals who have been immunized are subsequently given Schick tests in order that appropriate procedure for the control of an immediate allergic response may be instituted.

Inhibitory Action of Colloidal Sulphur in Corper's Agar on the Growth of Four Strains of Mycobacterium Tuberculosis Hominis

A. B. MASSEY AND G. E. SNIDER *

Associate Professor of Bacteriology and Plant Pathology, Virginia Polytechnic Institute, Blacksburg, Va.; and Instructor in Bacteriology, Medical College of Virginia, Richmond, Va.

LAWSON and Bengtson [1] found that the growth of a strain of *Mycobacterium tuberculosis hominis*, which was isolated from sputum in the spring of 1933, was inhibited by the addition of 1.5 mg. of colloidal sulphur per 100 ml. of Corper's potato-glycerin agar.

This paper is a brief report of work done in collaboration with the above mentioned workers. Four strains of *Myc. tuberculosis hominis* were used, including the strain used by Lawson and Bengtson. Strain " L " was culture No. 4173 of the American Type Culture Collection. It was isolated by E. J. Lynch, Laurel Heights, Shelton, Conn., May, 1927, and was still virulent to guinea pigs in September, 1927. It came to us on glycerin agar, and probably had been so maintained for a number of transfers. After the third transfer on Corper's potato agar it proved to be a very rapid grower.

Strain " H " was obtained from Dr. Zinsser of Harvard, and was referred to by him as an old laboratory strain originally isolated in Saranac, N. Y. We judge this to be the well known " H-37 " strain. This culture was on egg medium when received.

Strain " R " was obtained from Dr. Theobald Smith of the Rockefeller Institute. It was isolated from human sputum by passage through a guinea pig in April, 1933, and had been maintained on egg medium.

Strain " C " was that studied by Lawson and Bengtson and isolated by the latter from sputum in April, 1933. It was received on Corper's agar, on which medium it had passed several generations. Strain " C " was the only one accustomed to Corper's agar when received in this laboratory. Consequently, the results with the first few series of cultures compared with the other strains show discrepancies which, no doubt, were due to the change of culture media.

The medium used was Corper's potato-glycerin agar prepared by the same procedure as followed by Lawson and Bengtson in their work. The reaction of the medium was adjusted colorimetrically to a pH of 7.2 to 7.4, after which the hot agar was distributed into bottles containing sulphur. These were autoclaved for 20 minutes at 15 lb. pressure, removed from the autoclave, the hot agar tubed aseptically into 17 mm. diameter tubes, and slanted in pans of crushed ice. Inoculations were made by smearing a loop of a physio-

* This work was done while Mr. Snider was a Fellow in Bacteriology in the Virginia Polytechnic Institute.

logical salt suspension of the organisms over the surface of the slant. The tubes were closed by inserting a paraffined cork above the cotton plug. A groove was cut in one side of the cork for ventilation.

The following conclusions seem to be warranted:

Strain " L," an old culture of *Myc. tuberculosis hominis*, is a very rapid grower on Corper's agar (good growth appearing in several days), and tolerates at least 200 mg. of colloidal sulphur per 100 ml. of agar; however, some inhibition is noticed on agar containing between 7 mg. and 200 mg. of sulphur. Tests indicate that this strain is only slightly, if at all, virulent for guinea pigs.

Strain " H " tolerated 5 mg. of colloidal sulphur per 100 ml. of Corper's agar, though very little growth is obtained on agar containing this amount of sulphur. It is indicated that this strain is moderately virulent for guinea pigs.

The recently isolated strains, " R " and " C," did not grow on agar containing more than .1.5 mg. of sulphur per 100 ml. These strains are of practically the same age and were found to be highly virulent for guinea pigs.

The original experiments were suggested from observations of Dr. Lawson of the statistics of the incidence of tuberculosis among workers in the dust trades; which indicated that there is a lower incidence among sulphur workers. Our work indicates that there is a negative correlation between the virulence of the organism and the amount of sulphur tolerated. It is apparent that a much larger number of tests must be made before anything positive may be stated as to such a correlation, and we cannot, as yet, give any explanation as to the apparent lower incidence of tuberculosis among sulphur workers. While our results are drawn from study of hundreds of cultures of 4 strains it is essential that the tests for sulphur tolerance be made with a much larger number of strains. We are also unable to explain the reasons for the inhibitory action of sulphur but would venture the hypothesis that by direct action on the sulphur the organism produces toxic thionic acids or thionates. During the process of autoclaving the medium some hydrogen sulphide is evolved, but this is not enough to inhibit growth, as has been shown by experiments. There does not seem to be enough change in the pH of the medium to check growth.

Causes of Insanity

IN a recent total of 660 cases of Insanity studied by the American Medical Association, the statistics of the causes of insanity were reported as follows:

Drunkenness, 110; Social diseases, 100; Ambition, 73; Excessive Labor, 73; Misfortune, 69; Old age, 69; Disappointment, 54; Love, 47; Religion, 29; Politics, 26; Crime, 10.

Significance of the Small Variety Endameba Histolytica*

BERTHA KAPLAN SPECTOR, PH.D.

Associate Protozoölogist, U. S. Public Health Service, and Research Associate, Department of Medicine, Douglas Smith Foundation of the University of Chicago, Chicago, Ill.

IN December, 1933, the *E. histolytica* producing small variety cysts attracted attention in Chicago and soon assumed a prominent rôle in the parasitology of the human intestinal tract. It reached its climax in June, 1934; declined gradually until December, picked up again in January, February, and March, 1935; and declined until September, 1935. Now it is almost impossible to find an individual heavily infested with the small variety *E. histolytica* cysts.

E. histolytica is a collective species composed of distinct strains differentiated by the size of their cysts. Wenyon and O'Connor state: "Cysts of *E. histolytica* vary greatly in size. There occur strains of *E. histolytica* 7–10 microns in diameter, strains with intermediate cysts, and finally large strains with cysts 15–19 μ in diameter."[1] Also, "Cases infested with the small strain pass small cysts regularly, at any rate for some weeks, with no tendency for the small cysts to be replaced by the larger ones."[1]

In 1909, Elmassian[2] described the first precystic stage of *E. histolytica*, considering it a distinct species and naming it "E. minuta" as distinguished from *E. histolytica*, the large form. He stated that *E. minuta* give rise to cysts 10–16 μ in diameter.

In 1912, Prowazek[3] called these "*E. hartmanni*." In 1913, Kuenen and Swellengrebel[4] called the large *E. histolytica* forms "*E. tetragena*" and the precysts "minuta" forms. They give the following measurements for *E. histolytica*: *E. histolytica* 20–40 μ, "minuta" stages 12–20 μ, and cysts 10–15 and rarely 19 μ. In 1914, Ujihara[5] encountered very small as well as large cysts: 10–13 μ, rarely 3.4–4.27 μ. Wenyon and O'Connor,[1] 1917, give 7–19 μ as the diameters for *E. histolytica* cysts. In 1917–1918, Dobell and Jepps,[6] in their study of the diverse races of *E. histolytica* found that the cysts vary from 5–20 μ in diameter; 7–8 μ being commonest among the small cysts. They found that different races of *E. histolytica* may coexist. Brug,[7] 1917, gives 7–20 μ (average of 10–15 μ) for *E. histolytica* cysts. Dobell and O'Connor,[8] 1921, give very careful descriptions of *E. histolytica* and discuss their various races. Brumpt,[9] 1927, speaks of *E. minuta* as a non-pathogenic ameba producing cysts 5–10 μ in diameter. Craig,[10] 1934, reviews the literature on the subject and quotes the work of Dobell and Jepps, who have described 5 races of *E. histolytica* differentiated

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

by the size of cysts produced: 6.6, 8.3, 11.6, 13.3, and 15 μ. He quotes Boeck,[11] who divides the races into 3 groups: small, having cysts 6–9 μ, medium with cysts 10–12 μ, and large, 13–15 μ in diameter.

It may be well to cite the essential characteristics of the *Endameba histolytica* which produce large cysts and differentiate from it those producing small cysts.

TROPHOZOITES

Cytologically the trophozoites of *E. histolytica* have clear, hyaline, refractile, glass-like ectoplasm and finely granular endoplasm. The ectoplasm is best seen in the motile amebae. The motility is usually in a straight line by means of a single large, blade-like pseudopodium which moves rapidly and explosively. Usually the nucleus flows into the pseudopodium first, the red blood cells, if present, and finely granular material follow it. In fresh bloody mucous stools (from acute cases of amebic dysentery) the motility is very rapid. In cold stools the organisms are sluggish and the pseudopodia are more commonly blunt.

In stained preparations (iron hematoxylin) the nuclear membrane appears thin and delicate, upon the inner surface of which is a ring of minute chromatin granules. In the center of the nucleus or less commonly slightly eccentrically is a small black dot of chromatin, the karyosome which is about 0.5 μ in diameter. The karyosome is surrounded by a clear achromatic zone or halo. Between the karyosome and the peripheral layer of chromatin granules is an achromatic linin network. In degenerating amebae, however, there may be masses of chromatin in this network.

PRECYSTIC STAGE

Before encystment the active forms leave the tissues, enter the lumen of the gut where they undergo one or two divisions, diminish in size, lose motility, rid themselves of red blood cells, become spherical or oval in shape, and thus become precysts. In the living unstained condition the precystic *E. histolytica* appear colorless, hyaline, or finely granular, round or slightly oval, measuring 6–20 or more μ in diameter. The distinction between ecto- and endoplasm is less apparent than in the trophozoites. Progressive motility is absent, although blunt pseudopodia may be sent out, but the organisms commonly remain stationary. The nuclear structure is the same as in the trophozoite and the nucleus is usually more clearly visible. The precyst secretes a delicate wall and encysts.

CYSTIC STAGE

In living unstained preparations (saline or water) the cysts appear as colorless, hyaline bodies, usually round, but they may be oval. The cyst wall is refractile, fairly thin, and has a double contour. The nuclei appear as refractile bodies. The chromatoid bodies appear as refractile bars or rods with blunt ends. The cytoplasm is free from inclusions and appears clear. In iodine preparations (5 per cent aqueous potassium iodide saturated with iodine and diluted with equal parts of distilled water for use) the cyst and nuclear walls appear dark brown, the glycogen stains a diffuse brown, and the karyosome appears as a refractile dot. In iron hematoxylin preparations the cytoplasm appears bluish gray, the chromatoid bodies as black rods with blunt ends, the karyosomes and nuclear walls black. The glycogen appears as a vacuole. In old cysts the glycogen and chromatoid bodies are usually absent (used up as reserve food). In cysts with 1 and 2 nuclei the nuclear membrane is usually the same as in the trophozoite, but in the 4 nuclear stage the nuclei are smaller and membrane finer.

The *E. histolytica* producing small cysts differ from those producing large cysts physiologically, culturally, immunologically, clinically, and in pathogenicity for lower animals.

The trophozoites of the *E. histolytica* producing small cysts are usually smaller and not so motile as those producing large cysts, and they do not ingest red blood cells.

Bloody mucous stools from acute cases of amebic dysentery usually show quite large and very motile trophozoites, whereas the trophozoites found in soft stools from mild cases of amebic dysentery and carriers are usually smaller in size, approaching those giving rise to the small variety *E. histolytica* cysts.

The *E. histolytica* producing small variety cysts differ culturally from those producing large variety cysts. They grow infrequently (5–8 per cent) and with greater difficulty in Cleveland and Collier's medium * in which the large variety grows readily and luxuriantly. In my experience, cultures for *E. histolytica* from bloody mucous stools of active cases of amebic dysentery were positive in 100 per cent of the cases (49 cases), but only about 95 per cent of the cultures of stools from carriers of the large variety *E. histolytica* were positive (30 carriers). These figures are of clinical patients seeking medical care and are higher than those of food handlers, some of whom take amebicides before coming for examination in order to get a negative report, the reason being that they may retain their positions or get new ones. Arsenic was found in some of the stools that showed large variety *E. histolytica* cysts which failed to grow in culture.

In culture the trophozoites of the small variety may be small or they may be as large as those of the large variety. They may be long and slender or short and slender. The morphology and motility are identical with those producing large cysts.

The cultures of the small variety *E. histolytica* must be sub-cultured every 24–48 hours, whereas those of the large variety need not be sub-cultured so frequently—every 48–72 hours is sufficient. The *E. histolytica* producing small cysts differ immunologically from those producing large cysts. They fail to give positive complement-fixation when the antigen prepared from the sediment of cultures of *E. histolytica* producing large cysts is used in tests with serum from patients infected with the small variety *E. histolytica*. Complement-fixation tests with sera from 25 patients infected with the small variety *E. histolytica* were thus run, all of which gave negative reactions, whereas sera of untreated cases of the large variety *E. histolytica* tested similarly gave strongly positive reactions in almost every instance. See Table I.

TABLE I

SHOWING THE CORRELATION BETWEEN INFECTION WITH E. HISTOLYTICA (LARGE VARIETY) AND COMPLEMENT-FIXATION TESTS USING THE ANTI-SHEEP SYSTEM

E. histolytica Infection	*Complement-Fixation Tests* +	*Complement-Fixation Tests* —	*Total*
Pos. dysentery	13	3	16
Pos. carriers	2	3	5
Neg.	15	135	150
Total	30	141	171

CLINICAL ASPECTS

The clinical picture is rather indefinite, but the patients frequently

* The medium consists of 30 gm. liver infusion agar (Digestive Ferments Co., Detroit, Mich.), 3 gm. dehydrated sodium phosphate, 1,000 c.c. distilled water. Dissolve, tube, autoclave 15 lb. for 30 minutes and slant. These slants are overlaid with sterile serum—saline (1–6), sterilized by filtering through a Berkefeldt filter and testing for sterility. Wassermann negative human inactivated serum, horse, rabbit, or other sera may be used. A little sterile rice flour or rice starch is added to the medium before making sub-cultures if one desires to maintain positive cultures. Rice starch or rice flour need not be added for diagnostic purposes.

3 cleared on medication and 1 improved.

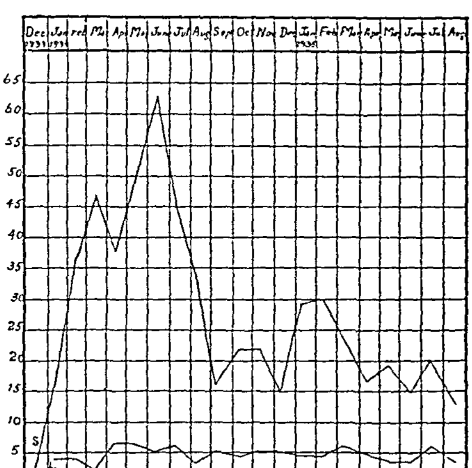
complain of distress and crampy pain in the abdomen followed by 2 or 3 soft stools usually in the morning, a feeling of fatigue, and the elimination of large amounts of gas. Ulceration of the rectum, pus, gross blood, or evidence of organic involvement of the colon have not been encountered nor have liver abscesses been observed with this variety.

The data[12] of 82 cases (7 food handlers of whom only 1 complained of abdominal cramps) are of interest (Table II).

Practically all of the data in Table III are of persons with sufficient intestinal symptoms justifying stool examinations for *E. histolytica*. Routine stool examinations were not made of hospital and clinic patients. (There were, however, several food handlers and contacts with clinical cases.)

There is a difference of opinion as to whether the *E. histolytica* producing the small cysts are pathogenic. The symptoms are much milder than those caused by the large variety, yet they seem to be typical and are eliminated upon specific treatment, especially if the symptoms are of short duration. (The longer the duration of the symptoms, the less readily did the patients respond to amebicidal treatment.) A number of persons, including members of the staff, infected with the small variety *E. histolytica* have been observed whose complaints seemed to have been typical and whose symptoms cleared up upon specific medication. Until we know more about these organisms, infected persons showing symptoms should be treated.

In our experience, liver and lung abscesses have not been produced by the small variety *E. histolytica*. In none of our cases of amebic liver or lung abscesses were we able to find small cysts in the stools, whereas in every such case the large variety *E.*



S = Small
L = Large

FIGURE I—Showing Number of Cases of Amebiasis Among the Clinic and Hospital Patients at the University of Chicago Clinics from the Summer of 1933 to September, 1935.

histolytica had been found. (We have had 4 patients with liver abscesses and 2 with both lung and liver abscesses.)

Our experiments on the pathogenicity for lower animals are still in progress. Thus far, by feeding experiments, we have been able to infect 8 out of 37 kittens with the small variety *E. histolytica* cysts, of which 2 showed minute ulcers of the large bowel, and 10 out of 22 with the large variety.

Intra-rectal inoculations of kittens with bloody mucous stools from amebic dysentery as well as with cultures of the large variety resulted in typical and severe amebic ulceration of the large bowels, whereas similar inoculations with cultures of the small variety *E. histolytica* have thus far failed to produce such results.

Faust, on the other hand, has observed fulminating dysentery in dogs resulting from small cysts taken from human carriers.

DISCUSSION

In the summer of 1933 when the Chicago epidemic started we did not encounter the small variety of cysts. They made their first appearance in December, 1933, and soon assumed a prominent rôle, reaching their height in June, 1934, declining gradually until December of the same year, picking

up again in January, February, and March, 1935, and have been on the decline since then (see Table III).

We do not know where they came from nor what is becoming of them. We know that they appeared in December, 1933, became widely distributed among the people of Chicago and its environs and perhaps in the entire country, assuming a prominent place in the parasitology of the human intestinal tract. When these cysts first appeared, they were typically round and quite numerous, most of the positive stools containing large numbers. This condition persisted for almost a year when more pleomorphic forms, irregular in shape, started to appear, and their incidence as well as number in infected individuals have decreased. At present it seems almost impossible to get a heavily infected specimen.

Table III gives the number of cases of amebiasis by month among the hospital and clinic patients examined from the summer of 1933 to September, 1935, at the University of Chicago Clinics. Under "small" we have included all the varieties from 5 μ or less up to about 12 μ in diameter which includes the intermediate forms.

In our experience, *E. histolytica* may produce cysts ranging from 5 μ or less to 20 μ in diameter. At times one encounters cysts so small that only those well trained at the microscope detect them. Since *E. histolytica* cysts range between 5 μ or less to 20 μ in diameter, thus overlapping *E. coli* and *Endolimax nana*, it is important to differentiate between these cysts.

CONCLUSIONS

1. The *E. histolytica* producing small cysts differ from those producing large cysts—culturally, immunologically, clinically, and in pathogenicity for lower animals.
2. *E. histolytica* comprise many strains or "races" differentiated by the size of cysts produced.
3. These different races may coexist in the same individual.
4. The *E. histolytica* producing small cysts seem to produce milder symptoms than the large variety, but we have no definite evidence that they produce intestinal ulceration. Specific medication seems to eliminate the symptoms as well as the parasites.
5. In our experience liver and lung abscesses have not been produced by the *E. histolytica* producing small cysts. These are produced by the *E. histolytica* producing large cysts.
6. Since the *E. histolytica* cysts vary from about 5 μ or less to about 20 μ in diameter, overlapping *E. coli* and *Endolimax nana* cysts, it is important to differentiate these cysts.

An Evaluation of Huddleson's Dye Bacteriostatis and Hydrogen Sulphide Methods for the Identification of Brucella*

G. D. CUMMINGS, PH.D., F.A.P.H.A.

Bureau of Laboratories, State Department of Health, Lansing, Mich.

THE purpose of this study was to evaluate Huddleson's method for differentiating organisms of the Brucella group. Five state public health laboratories coöperated. The classification of strains is based on ability to grow on thionin liver infusion agar and on basic fuchsin liver infusion agar and on production of hydrogen sulphide. Seventy-five strains which had been previously classified by Huddleson were distributed. The method of classification and the number of strains used were as follows:

	Growth on *Thionin*	Growth on *Basic Fuchsin*	*Hydrogen Sulphide*
23 *Br. melitensis*	+	+	none or trace in 4 days
23 *Br. abortus*	—	+	moderate to marked in 2 days
29 *Br. suis*	+	—	moderate to marked in 4 days

The results from the five laboratories were tabulated and are summarized in the following statements.

Thionin Plates—Agreement was obtained on all the *Br. abortus* and all the *Br. suis* strains. Five of the *Br. melitensis* cultures failed to grow on this medium in two laboratories, and 8 others failed to grow in one of these laboratories.

Fuchsin Plates—Agreement was obtained on all the *Br. suis* strains. One laboratory failed to obtain growth with 1 *Br. melitensis* culture. This same laboratory disagreed with the other four on 4 *Br. abortus* strains and reported indefinite results with 2 other strains.

Hydrogen Sulphide—All laboratories agreed on all the *Br. suis* and *Br. melitensis* strains, on the basis of results obtained in the specified 4 day observation period. In all laboratories including Huddleson's 4 cultures of *Br. abortus* failed to produce hydrogen sulphide in 2 days or produced only a trace.

The data obtained in this study show that with reasonable care in technic excellent agreement between different laboratories can be obtained in these specific tests for differentiating the organisms of the Brucella group. The classification of the various strains was not as satisfactory but this was due chiefly to difficulty in the interpretation of the results of hydrogen sulphide formation. The *Br. suis* strains were classified best, the *Br. melitensis* strains next and the *Br. abortus* strains less satisfactorily. In view of the trouble encountered in the hydrogen sulphide test, it is recommended that the thionin and basic fuchsin media be used as a basis for classification and that the hydrogen sulphide test be regarded as of secondary importance.

* Abstract of paper read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

VENEREAL DISEASES

WE have called attention to the fact that among the six major objectives of Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, the control of syphilis is included.

It is needless to recite the difficulties in the way of control of venereal diseases in general. These have been recounted time and time again. In spite of many agencies devoted entirely or partly to the control of venereal diseases, there has been a constant increase in their incidence, certainly as far as the United States is concerned. There is perhaps no other single disease which plays so large a part in dealing injury to the population of our country as syphilis. Its effects are far reaching. The late Sir William Osler used to put it something like this—Venus and Bacchus are both hard masters; both demand payment, Bacchus promptly; Venus for practically the rest of one's life.

We believe that too many of the agencies interested in the control of venereal diseases have done preaching instead of practical work. Preaching will never get anywhere in the control of venereal diseases. Unfortunately perhaps, we do not at the present day see the pictures described by Astruc, in writing of the pandemic of the 15th century, so severe and far reaching as to be "one of the notable events in medical annals." "From the Pope of Rome on his throne to the lowest scullion in christendom, all were infected with syphilis" (Astruc). Syphilis is now mild compared to what it was at that time. Death is rare except in the very late stages. "Malignant types that are now curiosities were then the regular form of the disease and the mortality was enormous" (Osler). The worst forms of syphilis are seldom seen by general practitioners. A comparatively few years ago, before steam had controlled ocean traffic, one would encounter

practically untreated cases of syphilis on ships after long voyages, as from China to New York, but even in the experience of specialists in large cities, such cases are now comparatively rare. Doubtless if these were seen more often the medical profession in general would realize more keenly than it does the horrors of syphilis, and this would be reflected in the attitude of the average health officer.

A recent study[1] has brought out facts which should have wide circulation, not only among the profession, but also among people in general. In this study a 1 day census covering 49 representative counties in the United States, was made, and reports were received from 39,000 medical sources. It was shown that the prevalence rate for venereal diseases was 7.7 per 1,000 and that there are constantly under medical care for syphilis 4.3 and for gonorrhea 3.4 per 1,000. From the standpoint of control as well as of the patient himself, one of the worst features was shown to be that 71 per cent of those who had contracted syphilis did not apply for treatment until the infection had become late, and of those with gonorrhea 51 per cent did not apply until the disease had reached the chronic stage.

From the facts obtained, it is estimated that there are approximately 493,000 in this country constantly under treatment or observation for gonorrhea and 683,000 for syphilis, a venereal disease population of 1,176,000. Fresh infections per year are 4 per 1,000 for syphilis and 8 per 1,000 for gonorrhea, which justifies the estimate that there are each year 1,500,000 persons seeking treatment for early syphilis or gonorrhea. It is estimated that 7 out of every 100 individuals 40 years of age or over remain potential syphilitic problems as far as treatment goes. The highest attack rate for syphilis is in the early adult ages, 16 to 30 years. The trend for syphilis seems to be upward, with a possible 3.4 per cent increase in the rate per 1,000, but there is a decrease in the prevalence rate for early cases. This cannot be interpreted as evidence of progress in the control of the disease since it has been shown that many cases fail to seek treatment until the late stages and some remain untreated for life. The data concerning gonorrhea actually under treatment show that the number of cases has decreased, but there is evidence that this decrease reflects the neglect of treatment during the economic depression and not a decrease in the number of infections.

We believe that these figures demonstrate the wisdom of selecting syphilis as one of the major points of attack. If they do not tell the story clearly, argument cannot avail. We trust we are not unduly pessimistic in expressing doubts as to the immediate success of the movements against venereal disease proposed. Human nature has not changed greatly during many centuries. Venereal diseases have been with us since the dawn of history. We are entirely too much accustomed to them. Too many of our young men, for example, boast of having gonorrhea and regard it, if not as a matter or pride, as one showing that they know their way about and are men of the world.

Certainly, as far as this country goes at least, the right way of attacking the problem has not yet been demonstrated, in spite of the scientific knowledge we have concerning the diseases, methods of transmission, etc. We cannot frighten the average person about venereal diseases. Like the poor, we have them with us always and have become accustomed to them.

ANNUAL MEETING OF THE WESTERN BRANCH

MANY things conspired to make Vancouver the health center of the American continent during the meeting of the Western Branch. It is Jubilee year of the city. It is hard to believe that where this beautiful city now stands with its fine buildings, its extensive parks, its health centers, hospitals, and so forth, there was, only 50 years ago, a forest of gigantic firs. Marvelous are the works of man!

The celebration of the Jubilee year began properly on July 1, but His Worship the Mayor of Vancouver issued a proclamation declaring a "Health Week," and granting to the public health organizations meeting there the privilege of introducing the Jubilee festivities. Five organizations met during the week:

Canadian Public Health Association (25th Annual Meeting)
Western Branch A.P.H.A. (7th Annual Meeting)
Conference of State and Provincial Health Authorities of North America (51st Annual Meeting)
Canadian Tuberculosis Association (36th Annual Meeting)
British Columbia Public Health Association (1st Annual Meeting)

Of somewhat more remote interest, as far as public health matters are concerned, is the fact that June 23, one of the days of the meetings, the King's birthday took place and was celebrated in the city. Apart from the very real affection and admiration which all have for the British King, the occasion was made use of to raise money through a dinner for the cancer funds of the Province.

Perhaps most important of all is the fact that the five organizations got together principally in honor of Dr. H. E. Young, dean of the public health profession in Canada, a man who is as well known and as much beloved in the United States as in Canada. His services have been extraordinary in times of plenty but especially so in times of distress. Apart from his personality and his accomplishments, he is none the less noted for the number of young men who have taken their training under him and their inspiration from him.

The first two days of the meetings were given up to the State and Provincial Health Authorities of North America, the Canadian Tuberculosis Association, and the British Columbia Public Health Association. On Wednesday, the third day, meetings of the Canadian Public Health Association and the Western Branch of the American Public Health Association were begun conjointly.

The attendance was good and the papers were exceptionally so. Of course, there was a tendency to consider chiefly those things in public health which concern the West and the Northwest, but, after all, while certain conditions prevail in one section more than another, public health is a unity and all its aspects are of interest to those who have the general cause at heart.

A particularly interesting feature of the meetings was the very graceful gesture of conferring honorary life membership in the Canadian Public Health Association on Dr. Walter H. Brown, President of the American Public Health Association, and Dr. A. J. Chesley, Executive Secretary of the Conference of State and Provincial Health Authorities of North America. Dr. John W. S. McCullough, Toronto, and E. S. MacPhail, of Ottawa, were similarly honored.

The scientific exhibits were especially notable. The commercial exhibits were not extensive, but excellent, and it is particularly interesting to note that the firms supplying these exhibits were keenly interested in public health and the success of these meetings. In fact we have been told repeatedly that they made possible many of the arrangements for the meetings.

Abundant provision was made for the ladies, more abundant and perhaps more entertaining than for the men, probably because the ladies had nothing else to do, while the men were expected to work. However, the men were taken to see the water works of Greater Vancouver, a remarkably fine plant from mountain streams, with the watershed thoroughly protected and policed.

The meeting was notable as being the first joint meeting of the Canadian and American Public Health Associations, an example which we might do well to follow from time to time in the future. Some of the members of the Canadian association stated that the stronger the Canadian association becomes, the stronger will be their admiration and adherence to the parent Association in the States.

The meeting of the Western Branch was brought to a close on Friday evening, when the annual banquet was held, at which the new officers were installed, headed by Dr. H. E. Young as president. The new officers are as follows:

President—H. E. Young, M.D., Victoria, B. C.
President-Elect—Platt W. Covington, M.D., Salt Lake City, Utah
Vice-President—F. D. Stricker, M.D., Portland, Ore.
Vice-President—F. E. Trotter, M.D., Honolulu, Hawaii
Vice-President—J. Rosslyn Earp, Dr.P.H., Santa Fe, N. M.
Secretary—W. P. Shepard, M.D., San Francisco, Calif.
Treasurer—W. F. Higby, San Francisco, Calif.

The banquet was marked by two special features: the granting of an honorary life membership to Dr. Arthur J. McCormack and the presentation to the Western Branch by Dr. Young of a gavel, made of wood taken from the "Beaver," a vessel closely connected with the development of the West and the Northwest.

The members left for Victoria, some at midnight and some on Saturday morning. They were met at the dock by the health authorities of the Province and City. Citizens had provided cars in which the visitors were taken for beautiful drives through the city and about the island, including the wonderful Burchart Gardens.

Too much cannot be said of the hospitality shown by the citizens of Victoria and by the Provincial and City health authorities.

The weather was perfect—a trifle warm but not as warm as the reception which was given to delegates. The whole city conspired to make us welcome. Everything was done for our comfort, and for those who were privileged to attend there will remain for many years the most pleasant and grateful memories of the hospitality shown.

The 1937 meeting place of the Western Branch will be Phoenix, Ariz.

NOISE

DURING the past few decades infectious diseases have been better understood, and controlled to a considerable extent. The incidence of such diseases as tuberculosis, diphtheria, and typhoid fever has declined markedly. Drinking water has been purified. Sewage disposal is carried out in a decidedly more sanitary way than in earlier days. Streets are being kept cleaner. Dwellings, though universally not yet what they should be, are more sanitary. Coincident with these notable achievements from a public health standpoint there has crept into our lives a new

public health problem—noise. This has come about largely as the result of the extensive mechanization of our daily life by such devices as the automobile and radio.

Noise is unwanted auditory stimulation. Thus it may be seen that otherwise beautiful music may be noise. Unlike garbage or street dirt, noise has the peculiar property of radiating instantaneously in every direction from its source to annoy every one within the zone of its penetration.

Loudness is one of the most distressing attributes of noise. Its intensity may be measured in units, called decibels, by which the noise of a busy city street corner can be accurately compared with that of an automobile horn, the roar of a jungle animal, the loud speaker of a neighbor's radio, or the boisterous cocktail party in the wee hours of the morning in an otherwise quiet suburb. Although fatalities have seldom (if ever) been reported from noise directly, the eardrums of heavy artillerymen may be burst, and it is a well known fact that boilermakers become deaf.

Another aspect of noise that is annoying, to say the least, is the ambiguity of its direction. To puzzle about the source and the unfamiliarity of sounds that are distracting often prevents one from devoting his attention to more important things. Intellectual workers are more affected by noise than others. Nevertheless, some experiments with industrial workers indicate that noise prevention in factories tends to increase the quality and quantity of output and the workers have quite generally voiced greater satisfaction with quieter conditions and felt lessened fatigue.

Watson has demonstrated that noise is an elemental fear-producing stimulus. It is one of two things that will frighten a baby that has lived in a protected environment and has never experienced fear. From a physiological standpoint noises tend to increase muscular tension and thus the energies of many people are insidiously dissipated without their awareness. Although unawakened by noises at night, their effect on muscle tension deprives persons of adequate recuperation during sleep hours and unfits them for the ordeals of another day. The persistent accumulation of such effects may be tolerated by some people better than by others, but it is safe to say that millions are stimulated and harassed when they should rest properly to promote well-being.

There is little doubt that the people of the United States are among the noisiest. Much of it is unnecessary. New York City has done much recently to lessen its noise. Many cities, including London, Rome, and Paris, within the last year or two have completely controlled the automobile horn by ordinance. Despite belief to the contrary, there was a reduction in automobile accidents in these cities after these ordinances went into effect—a fine demonstration that drivers could use their heads instead of their horns.

In some countries for many years anti-noise societies have been organized to arouse the public consciousness to the importance of noise prevention. The responsibility of manufacturers and merchants in these matters is clear. Quiet automobiles, street cars, radios, home devices, will be in demand to replace the noisy ones. Individuals have a great responsibility. The time should not be far distant when it may be as much a breach of good manners and public health to to emit an unnecessary noise as it is to expectorate on the sidewalk. When the public gets sufficiently conscious of the need for preventing unnecessary noise, ordinances may not only be passed, but enforced, to protect every one. Hospital zones are now protected by law. If such measures are good for the ill, they

will undoubtedly help to keep many not acutely ill from being uneasy or dis-eased. With noise on the increase, cities must be planned in the future to protect their citizens. The proper construction of dwellings, the arrangement of streets and parks, with sound-absorbing trees, shrubs and vines, and quiet, efficient transportation systems leading to decentralization of overpopulated regions, hold possibilities as yet but little realized.

This problem, so essential to coöperative living, should be a challenge to education. Children should be taught noise prevention as well as cube root. There was a time when we were ignorant of and indifferent to the consequences of polluted water supplies. This is now interesting history. There will be a time when society will look back and say, "How could they exist with such a jumble of barbaric noises to harass the equanimity of man!"

INTESTINAL ANTHRAX

THE older literature carries accounts of a number of serious outbreaks of intestinal anthrax due to infected food. Such reports are now so extremely rare that they deserve mention in order to keep physicians and health officers on their guard, especially as the diagnosis is not easy to make and is only positive after laboratory examinations.

The outbreak in question [1] occurred in September, 1934, in a Rumanian regiment stationed on the western shore of the Black Sea. It was confined to private soldiers, 14.5 per cent of whom were attacked with severe gastrointestinal symptoms, muscular weakness and chills, with a case fatality rate of 30 per cent. Autopsy revealed an extensive enteritis with hemorrhages in the lower part of the ileum. The diagnosis was confirmed by the findings of the laboratory at Bucharest. Several diagnoses were made—food poisoning, paratyphoid B, and even cholera being suspected. The infection was traced to food eaten by the troops in transit between Jassy and Constantza.

In September Journal

PUBLIC HEALTH EDUCATION*

"Death In Safety Week"—Under this title, Dr. N. L. Burnette of Ottawa, and in an editorial headed "The Accident Problem: An Opportunity and a Responsibility," automobile accidents are presented as a public health problem.

Dr. Burnette says:

> Might it not be that in the major causes of accidents we are dealing unknowingly with a certain proportion of medical, neurological, and psychiatric cases? It would seem worth while to explore this possibility. Certainly we will never touch these cases through our present methods of initial driving instruction and licensing, nor will we ever correct their faulty driving habits through exhortations to be careful.

The editorial further emphasizes the actual ignorance of health and control authorities as to the real nature of the problem.

> The derivation of the word accident indicates that it was formerly employed to denote an event unpreventable and unforseen, or due to chance. This conception is still widely held in the public mind, but the sooner the conception of accident as a chance or unfortunate event, the result of "bad luck," etc., is discarded, the better. Scientific evidence has shown that many accidents have an explanation in physiological and psychological defects or maladjustments and inadequacies of the persons involved. Once the relative importance and the character of the various causes of accidents are determined, the solution would become clear and there is no doubt that "the human factor" is one to which increasing attention must be paid
>
> As a result of our ignorance in regard to the underlying factors involved in accidents, the methods of prevention and control which have been employed have lacked any semblance of the scientific approach which is so necessary to success.

The "conclusions" of Dr. Burnette:

> 1. Death and injuries from automobile accidents have reached a volume where the public health field must be concerned about them.
> 2. In many major causes of accidents, the reasons advanced are purely guesses.
> 3. Safety education cannot be successful until its teaching is based on the proper application of tested methods designed to correct conditions for which the cause has been established.
> 4. Public health organization could bring into the field of safety education a viewpoint at present lacking because public health is based on preventive medicine and the traditional attitude of preventive medicine is experimentally to establish causes and test methods of control before embarking upon propaganda.
> 5. In public health work, there is already a well established precedent for combining medical knowledge with engineering and pedagogical psychology.
> 6. Public health should interest itself in traffic accidents, to the end that, with the exception of such matters as highway construction, law enforcement, and certain factors in motor engineering, the public will eventually look to the public health field for the explanation of important problems, as well as leadership in plans for their solution.

The reasoning of the writers sets up a fresh objective for health education in automobile safety. The long range job is to lead public health and other authorities to a new viewpoint and a new line of attack.

Editors of bulletins or house organs will wish to quote liberally from the full text of the article and the editorial.

In *Canadian Public Health Journal,* 105 Bond St., Toronto 2, Ontario. June, 1936. *35 cents.*

---

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

To Health Educators Everywhere—To you is addressed this message from Dr. W. W. Bauer, Chairman, Public Health Education Section:

The American Public Health Association, Public Health Education Section, wants to be of the greatest possible service to everyone interested in health education. One of the best ways to accomplish such a purpose is to exchange ideas. There is no one who has a monopoly on originality. Not all the good ideas come from persons whose names are well known, nor do they all originate in the big and well financed health education agencies. The lone worker in public health such as the nurse in a distant county may contribute an idea which is fresher and more original than the most elaborately conceived plans of the health educator in a national agency.

Health education is basically the same in all countries because human beings are basically alike. Differences in language and customs are superficial. The peoples of all lands respond to the same basic appeals.

All this merely leads up to what I wish to say in support of the paragraph "To Our Readers In All Lands" which appeared in this department last month. As the meeting of the American Public Health Association at New Orleans approaches, we are particularly eager to hear from readers of this department in foreign countries. If you cannot be present, will you not send your materials to the Clinic Session of the Public Health Education Section at which they will be discussed. We would like you to send posters, pamphlets, film strips, motion pictures, and exhibits. If the material itself is too bulky, send photographs and descriptions. Be sure to tell how it was made, what it cost for equipment, what it costs to keep in operation, and what responses it has brought. Of especial interest are devices which show originality and which have been developed without the expenditure of unusually large sums of money.

Syphilis Campaigns Desirable—Active effort throughout the year, plus short term intensive campaigns are desirable against syphilis, according to Savel Zimand writing in *Better Times*, Welfare Council, 122 E. 22d St., New York, N. Y. June, 1936. *35 cents.*

The "taboos" associated with this subject can be overcome and the campaign approach is especially useful for this purpose.

The aims of the syphilis campaign should be two-fold: to familiarize the people with the essential facts concerning the disease and to induce as many persons as possible, suffering from syphilis, to seek advice and treatment. At every turn of the campaign difficulties of approach will be encountered, but these can be overcome by tactful methods. . . .

The instruments popularly used for conducting mass health educational work are varied, but whatever their nature, there are certain fundamental conditions without which they cannot accomplish their purpose. These are: scientific accuracy, emotional appeal, concreteness, and simplicity.

A "campaign" may be city-wide or limited to a certain district. In either case, the active support of the medical profession, nurses, social workers, religious leaders, head of industries, etc., should be obtained. The organized health center districts of the health department continuously receive generous assistance from the medical advisory and general advisory committees of the centers.

In addition to this active participation from organized groups, it will prove useful to secure the support of a group of outstanding citizens residing in the district. Such volunteer committees may well include among others a considerable representation of leading conservative elements of the community.

The outstanding clergyman of the district, the respected chairman of the local women's club, the outstanding civic, physician, or business leader, presiding at a meeting for dissemination of facts on syphilis, will do a great deal to bring general community approval of this work. It will often add to the effectiveness of lectures or meetings if they are conducted in church houses or at women's clubs. . . .

The "campaign" approach in itself is not

sufficient. The campaign should be supplemented by personal instruction of individuals through private physicians, health department staffs, nurses, social workers, and teachers, all of whom can and are influencing the conduct of the public. We should try to determine the nature and extent of any objections to the discussion of these diseases, so that, as far as possible, they may be overcome. To this end it is well that the enlightened men and women of the community understand and accept the new orientation on venereal diseases. They will help to destroy the false taboos created about these diseases.

New Orleans in October, 1936—At the Annual Meeting of A.P.H.A. the Public Health Education Section will provide a series of programs for those concerned with adult health education, together with recognition of the specialized interests of those engaged in child health education.

Many other programs will supply useful material and mental stimulus for both adult and child health educators.

As usual, the "lobby sessions" will bring the personal contacts and exchange of experiences which are so valuable to alert public health workers.

If present plans are realized a health education headquarters and display will be maintained. *It is hoped to give special attention to personal conferences.* Delegates are invited to plan in advance outlines of their problems and the kinds of information they would like to gather at New Orleans. They are requested to come well prepared to talk over the details of their local or state health education programs.

A portfolio of specimens, with generous explanatory notations, would be appreciated by many of the visitors.

"Mass Education On Marriage"—How to reach numbers of young people is discussed under the above title in *Journal of Social Hygiene,* 50 W. 50th St., New York, N. Y. March, 1936. *35 cents.*

Marriage education experts such as Professor Maurice A. Bigelow and Paul Popenoe believe that the thing to do is to "begin where they are." In other words, to provide educational information at the point and from the sources through which this large group receives most of its knowledge. Among these sources the newspapers are chief, and Professor Bigelow and Mr. Popenoe have experimented during the past year with a number of feature articles, prepared in popular style by special writers. Such titles as "By All Means," "Let 'Em Marry Young," "How to Make Love to Your Wife," and "Do College Girls Make the Worst Wives?" vie with feature story headlines on other topics, and wide circulation is assured by release through press services such as the King Features Syndicate and the *Every Week Magazine,* which serve hundreds of newspapers. Even the dignified *New York Times Magazine* recently published an original article by Mr. Popenoe entitled "Is There a Scarcity of Good Husbands?" Under these attention-getting titles the authors of course set forth solid, accurate educational facts, and the many inquiries and comments received prove the effectiveness of this method of education.

Newspaper fiction also may be effective, as witness the short story, "No Right to Marry," by Margaret Culkin Banning, reprinted in this number of the Journal from the *New York Herald-Tribune's* Sunday magazine, *This Week.*

The monthly magazine, another source of popular information, are open channels for marriage education. Such articles as "Marriage a la Campus," by Florence Haxton Britten, in November, 1935, *Red Book,* which summarized the opinions of a dozen or so college deans on the pros and cons of marriage during student days, and the articles "Can't I Save My Marriage?" and "Repeat Course in Matrimony," in *Good Housekeeping,** discussing divorce prevention, are real marriage education placed where it will do the most good.

The radio, too, which reaches this same group of "normal young people" offers great opportunity for marriage education, but so far this opportunity has not been fully realized. Many single talks, and short series of talks, on marriage and family problems have been given by various speakers, but it yet remains for some leader in this educational field to build up a day-to-day program and the large popular following

* See issues for January, 1935, and February, 1936.

among young people which such a program deserves. Neither have the possibilities for dramatizing such material over the air been utilized, to the extent that they offer.

One more great medium of education, for young and old, should be more fully employed for constructive efforts. When the motion picture screen and its talking accompaniment really sets about showing young people normal, wholesome marriage and family life with the same thoroughness with which the seamy side of these relations has in the past often been exploited, progress in mass education on marriage will really occur. Recent films show promise in this respect. Let us hope for further encouraging developments.

Learning the Language and Understanding It—When we interpret health work to the community, or seek to influence the health habits of adults and young people we face a wide range of technics from which to select our weapons.

Not many of us will have the time to become thoroughly at home with printing, photography, optical projection, broadcasting, etc. But we do need to know our way about, and to talk intelligently with those who are specialists in one or the other of the technics we may wish to utilize.

A similar situation faces many men in commercial advertising. What to do about it is illustrated by suggestions to advertising people who need to learn more about photography and the reproduction of photographs. The answer is entitled "Camera!" by R. Hertzberg.

A superficial acquaintance with cameras and dark rooms, gained from occasional visits to studios and engraving shops, proves embarrassingly inadequate when you are called upon to discuss . . . with the production people at the plants. Needless to say, such ignorance leads to unnecessary grief and expense.

The simplest, cheapest, and most pleasurable way to acquire an understanding of photography is to become a photographer yourself—on a small scale, of course. If you don't already own a camera . . . buy an inexpensive one that will take pictures at least "vest pocket" size ($1\frac{5}{8} \times 2\frac{1}{4}$ inches), or larger. Also buy a developing and printing kit, which includes everything you need for the actual production of photographs. You can spend as little as five dollars for the whole outfit, camera and all.

The bathroom at home, with the shade drawn and a breadboard across the hand basin for a work table, makes a perfectly good darkroom. Shoot a roll of film of the wife and kids in bright sunshine, read the instruction book, and go to it. You'll get a tremendous kick watching the images come up on the negative, and you'll get another thrill when you make the positives, or contact prints.

After an hour's dabbling, you'll have a clear picture (no pun intended!) of how a negative, made by a camera from a . . . is "printed" photographically on sensitized zinc to make a planographic printing plate for the offset press; and how a similar negative . . .

Of course, other manipulations are involved. For instance, . . . These other operations become mere details once you see for yourself how a negative is made from a piece of copy (which is a positive) and how other positives can be made from negatives and more negatives from these positives and progressively without end.

The next step is to learn how enlargements and reductions are made from either negatives or positives, usually the former. The popular Eastman Kodak book "How to Make Good Pictures," will give you a general idea; a visit to your photographer's studio will make the mechanical-optical processes clear. From then on, planographic and intaglio printing will hold no terrors for you.

If you are naturally lazy or lack experimental inclinations, make a date to spend several hours, or half a day, at your photographer's place, and at least observe how he works. However, prepare yourself by reading the early chapters of the aforementioned book, so that you won't have to ask silly questions. Your picture man will be glad to give you darkroom demonstrations, because a better understanding of photography on your part will simplify his job to a large extent.

Of course, a visit to the offset or roto house that does your work will also be of educational value. If you display any knowledge at all of photography, you'll find that the men will be anxious to explain every detail and will take the time to do so. The visitor who knows nothing about photography is rushed through with a lot of

mumbled explanations. He is merely impressed by the dazzling lights, the smelly *darkrooms, the air-conditioned retouching* rooms and the noisy pressroom, and he leaves more confused than edified.

In *PM*, 325 W. 37th St., New York, N. Y. June, 1936.

A series of first hand contacts might be worked out in a city, or even a state where a group of interested people could come together for the purpose. Some one must do some wise planning in advance.

"For Sale by Superintendent of Documents"—Written by, published by, and for sale by, are usually functions of three different arms of the federal government. This simple fact seems unknown to many makers of reading lists, and editors of bulletins and other periodicals.

Elsewhere we mention a pamphlet, "What Every Teacher Should Know," etc. This was written by the U. S. Office of Education (through a staff member). It is published, or rather printed, by U. S. Government Printing Office; but it is "For sale by the Superintendent of Documents, Washington, D. C."

The simpler reference is the clearer, and takes less space. Readers usually wish to know not alone the name of the author, but also the sponsoring agency of the government. Beyond those facts, mention only "Superintendent of Documents, Washington, D. C.," and the price. To add "U. S. Government Printing Office" adds no more information of value than to mention the name of the printer of your annual report, or your new folder on measles. And it does cumber the page to add words without significance.

When an order is sent direct to the sponsoring part of the government the filling of the order must be delayed until the letter and the cash sent to the Office of Education (or whatever it may be) has been forwarded to the Superintendent of Documents.

Certain publications, carrying a price and "for sale by the Superintendent of Documents," will be supplied free if the sponsoring government agency is asked for a single copy. But this fact need not be allowed to confuse the printed reference.

Taboo Words—We need a taboo list, a black list of words not to be used in public health education. Some words are easily misunderstood. Other words are dull and heavy. Yet others are inaccurate, at least as they are commonly used. In the third class are words discussed in *Bulletin*, National Tuberculosis Association, 50 West 50th St., New York, N. Y., issue for July, 1936:

One of them is our old friend "tubercular" as a substitute for "tuberculous." The adjective "tubercular" (it can never be used correctly as a noun), means a nodular formation in the tissues of the body that is produced by something other than the tubercle bacillus. Any process caused by the tubercle bacillus is a "tuberculous," not a "tubercular" process.

Recently a newspaper in California wrote about a "tubercular test in a preventive campaign." Certainly the use of the term "tubercular" to describe a tuberculin test is about as wrong as wrong can be.

Another of these tabooed words is "preventative." Once in a while there is use for the noun "preventative" though usually the shorter word "preventive" is quite as good if not better. There is no use for the word "preventative" as an adjective; it is distinctly out of place used thus.

Hygeia, July, 1936—Material to use or to adapt:

Noise . . . Quacks and quackery . . . The tetanus bacillus . . . Cataract: its facts and fallacies . . . Tomorrow's drivers (safety education) . . . Cancer education: fight cancer with education . . . The care of the skin . . . How to follow the doctor's orders . . . The Martin family vacation (episodes V, VI, and VII) . . . The preschool child who misbehaves . . . The language of the heart

(electrocardiograph) . . . The gases of the air in medicine . . . Walking revelations (walking posture and its correction; see illustration) . . . Curious stories about health (a series) . . . A visit to Jenner's home . . . Everything in its proper place—even dogs . . . How diseases came with the white man (a series) . . . The ductless glands: the foremen of the body . . . Ivan Petrovich Pavlov: the Darwin of physiology (died in Moscow, February 27) . . . New books on health . . . Questions and answers.

In "School and Health":

Can the teacher help children to bear their physical defects and peculiarities? . . . A new health education course for a high school (Amherst, Mass.) . . . A high school class gets things done (Camden, N. J.) . . . A lesson plan on teaching safety in the third grade (Abcata, Calif.) . . . A copy free to a health worker or health teacher. Write to 535 N. Dearborn St., Chicago, Ill.

The "Martins," the Bauers, and Others—Here is more from the Bauers about their creation, the "Martin" family. Says Dr. Bauer:

I am not sure whether my good friend, Evart Routzahn was trying to start an argument when he asked "Why Memorize a Broadcast?" What Mrs. Bauer and I had in mind when we wrote that introduction and suggested the use of the Martin Family Vacation episodes in a darkened room with a radio in the spotlight was that it would be necessary to memorize broadcasts because of the absence of sufficient light to read the scripts. At the same time, we are grateful for the suggestion that the whole broadcasting process be reproduced in the bright light of publicity.

With respect to the further question about granting permission to produce material provided no admission charge is made, we amplify our attitude as follows: It was our purpose to grant, without further correspondence, the right to produce these plays by genuine health agencies. Such agencies customarily do not make an admission charge. It was not our purpose to grant permission to those who might wish to use this material in order to make money for purposes which might not be in accord with the objectives of public health. It is quite true, as suggested, that possibly we are, as health educators, giving away too much. Neither *Hygeia* nor the authors will raise any objections to having admission charged providing we are informed in advance as to who is going to charge admission and for what purposes. Success in getting a paid audience for health education material would, indeed, as suggested by Mr. Routzahn, "be a real achievement, and a distinct advance in getting attention for health messages."

Health Education for Pan America—The recent meeting in Washington of Pan American Conference of National Directors of Health gave quite a little attention to health education and to activities which call for phases of health education. Resolutions covered recommendations as follows:

Campaigns for the prevention of industrial accidents, etc., etc.
Extension of free maternity centers
Special education of women in hygiene and public health
Popularization of the newer knowledge of nutrition
Campaigns of education against drug addiction
Education of mothers in the prevention of trachoma

The above is reported in *Bulletin*, Pan American Union, Washington, D. C. June, 1936. *15 cents.*

BOOKS AND REPORTS

Veterinary Military History of the United States, with a Brief Record of Veterinary Education, Practice, Organization and Legislation—*2 Vol. By Louis A. Merillat, Lt. Col., Vet. Res., Chief Veterinary, American Expeditionary Forces, and Delvin M. Campbell, Lt. Col., Vet. Res., Editor, Veterinary Medicine, sponsored by the American Veterinary Medical Association. Chicago: Veterinary Magazine Corporation,* 1935. 1,173 pp. Price, $10.00.

The authors state that chapters I to IX are, in fact, the preface of this history, since the ground covered is too complex and extensive to be introduced in a few words. The authors say:

> We have undertaken for the first time not only the writing of an American veterinary history but also cultivating a taste for its details. . . . This book is the outgrowth of a series of articles published in 1932 on "The Veterinary Service of the American Expeditionary Forces" on the Western Front of the World War which were intended for publication in book form. . . . With these data as the inspiration it was decided to expand the manuscript so as to include the entire history of the military-veterinary service of the United States from the Revolutionary War to the present time, and to include a list of the World War veterinary officers, their ranks, promotions and assignments, and finally of all who had served in our army since 1879 when, by act of the Congress, graduation from a recognized veterinary college was made a prerequisite to such service.

Perusal of these volumes enables one to discern that the World War was not only the inspiration for the book but the explanation of why in the title they have used the word "military." If cognizance of these facts were not taken one might be inclined to criticise the title.

The authors have done a splendid work in compiling the history of our veterinary existence in the United States and have produced one of the most valuable contributions to veterinary science as a whole that have ever been made, for which they are to be congratulated.

This veterinary history will be of interest to the medical profession for two reasons: (1) that veterinary medicine and human medicine are allied subjects; (2) that at present the veterinary corps of the United States Army is under the direction of the Surgeon General, and so veterinarians, medical men, and others will find much of interest in this history.

The authors said in their preface that they were not only writing an American veterinary history but also cultivating a taste for its details. This is an actual fact. The reviewer has found the reading of these volumes intensely interesting, and would recommend them to all who desire to know the detailed facts not only of American veterinary history but of the experiences and functions of the veterinary corps during the World War.

It is regrettable that the authors in their prejudices against agricultural colleges and experiment stations have failed to include in this history the valuable contributions of these organizations the personnel of which have contributed unceasingly to the advancement of veterinary science in the United States.

The book is abundantly illustrated, mostly with reproductions of photo-

graphs. The veterinarians of the country in general and especially those who served during the World War, will recognize many of their old friends and comrades, and this holds true for the medical men who served with them.

A. J. DURANT

The Medicine-Man of the American Indian and His Cultural Background—*By William Thomas Corlett, M.D., L.R.C.P. Springfield, Ill.: Thomas,* 1936. 369 pp. Price, $5.00.

This is an unusual and an extremely interesting book. As the author says, it is not a medical book and contains "as much religion as medicine, and more theology than pathology." However, it tells us of the medicine-man of the American Indians and gives an insight into their way of thinking and their primitive methods in surgery as well as medicine. There has been among all peoples an ingrained longing for those who were able to mitigate pain and to preserve life, and all peoples have had physicians and priests, often combined in one person.

Among the Indians it has been impossible to separate the religious beliefs and rites from the practice of the healing art, and this accounts for the sacerdotal atmosphere found here and there throughout the book. Even in the witchcraft which was found among these aborigines, and in spite of its attendant enormities, we find useful elements, and in many ways the medicine-men were useful to the people and were held in high esteem.

In Part I we find a discussion of the racial origin of the American Indian and the peopling of the New World, the author concluding that the American Indian belongs to the Mangoloid division of the human race and that he came from Asia via the Bering Strait to the New World between 8,000 and 20,000 years ago.

In this Part also are treated the diseases of Indians, their religion, and their medicine-men. Following this, the various sections of the country beginning with the Arctic region and ending with Patagonia, are considered. The book shows a great amount of study and is amply documented.

The author frequently quotes Dr. Roy Lee Moodie, whose work on paleopathology is so well known, and credits him with giving advice and assistance in reading the manuscript as well as for lending photographs and other illustrations of objects of prehistoric as well as later periods. He points out that accounts of the aborigines have dwelt too much on their savagery and barbarism and not enough on their good qualities. What has ever been written finer than the speech of Nezahualcoyotl to his nobles, ending with this beautiful paragraph:

> The great, the wise, the valiant, the beautiful—alas! where are they now? They are all mingled with the clod; and that which has befallen them shall happen to us, and to those that come after us. Yet let us take courage, illustrious nobles and chieftains, true friends and loyal subjects, let us aspire to that heaven where all is eternal and corruption cannot come. The horrors of the tomb are but the cradle of the Sun, and the dark shadows of death are made brilliant by the light of the stars.

We cannot but feel sad that some of these splendid tribes have disappeared, that many of those remaining have become degraded through contact with the white man, and perhaps all of them are on the way to extinction.

The book is beautifully printed and profusely illustrated. Specimens showing operations such as trephining and even double trephining, dressings of head injuries, cupping for pneumonia, etc., are given. An excellent index completes the volume, which can be recommended on account of its historical as well as its scientific and social interests.

MAZŸCK P. RAVENEL

The Specificity of Serological Reactions—*By Karl Landsteiner, M.D. Springfield, Ill.: Thomas,* 1936. 178 pp. Price, $4.00.

This work is a critical review of both the old and new literature pertaining to serological specificity, with particular reference to the chemical aspects of specificity. It is a revision and extension of an earlier German edition by the author. It includes a discussion of the serological specificity of natural antigens and antibodies, including proteins and cellular antigens, of artificial conjugated antigens and reactions with chemical substances of known constitution, and a consideration of chemical investigations of specific cell substances, including carbohydrates and lipoids.

The author has included material sufficiently elementary to orientate the inexperienced worker in this field, and at the same time has included material of such complexity as to make the work invaluable to workers more familiar with this type of study. The bibliography accompanying each chapter is particularly valuable. The volume is unusually free from typographical or other errors. It is well printed on non-glazed paper. The name of the author assures us of the authenticity of the material. NEWELL R. ZIEGLER

Food, Health and Income: Report on a Survey of Adequacy of Diet in Relation to Income—*By John Boyd Orr. New York: Macmillan,* 1936. 72 pp. Price, $1.00.

It seems to be a well established principle of economics that more adequate nutrition and resultant better health are found in persons in the higher income groups than in those in the lower groups. This is confirmed by the noteworthy study conducted by Dr. Orr for the Rowett Institute, reported in this well printed monograph.

In order to determine the adequacy of the diets of the people of Great Britain, they were divided into 6 groups according to income, and the average diets of each were compared with the optimal requirements for nutrition, as suggested by Stiebeling of the U. S. Department of Agriculture.

The average diet of the poorest group, comprising some 4½ million people, was found to be deficient in every essential constituent, whereas in the highest income groups there was complete adequacy and even a surplus of all food constituents. Thus, in the poorest group, the consumption of milk was only 1.8 pints per head per week, but in the wealthiest group it was 5.5 pints. The wealthiest group spent about twice as much for eggs and fruits as the poorest group, but the consumption of bread and potatoes was practically uniform in all groups. To make the diet of the poorer groups adequate would involve an increase of from 12 to 25 per cent in their expenditures for milk, eggs, butter, fruit, vegetables, and meat.

"A review of the state of health of the people of the different groups," concludes the author, "suggests that, as income increases, disease and death rate decrease, children grow more quickly, adult stature is greater, and general health and physique improve."

The practical application of the newer knowledge of nutrition is a social problem demanding economic statesmanship, not only in Great Britain, but in the United States. This interesting report should be helpful in drawing attention to this world-wide problem. JAMES A. TOBEY

"Do's and Don'ts for Health, Happiness and Abundant Life"—*By John J. Sutter, M.D. Bluffton, Ohio: Bluffton News Printing and Publishing Co.,* 1935. 151 pp. Price, $1.00.

A compendium of short statements covering human habits and ailments

ranging from athlete's foot to "tantrums and tears."

Its chapters deal with brief essentials of health and happiness, prevention of diseases, accidents and hazards, nutritional diseases, and "essentials" for infants, children, and adults.

This is a unique presentation of the menaces to health, happiness and life, and the means of their avoidance.

CHARLES H. KEENE

The Diagnosis and Treatment of Pulmonary Tuberculosis—*By John B. Hawes, 2nd, M.D., and Moses J. Stone, M.D. Philadelphia: Lea & Febiger*, 1936. 215 pp. Price, $2.75.

Unique in its field, this small volume furnishes for practitioners, social workers, nurses, and students a brief, concise, and yet fairly complete summary of the present-day knowledge of the diagnosis and treatment of pulmonary tuberculosis. From more than a quarter of a century in the practice of medicine the authors have drawn vividly on their vast experience and have made a valuable contribution to the literature on tuberculosis.

A foreword by Dr. Richard C. Cabot sums up admirably the chief characteristics of the book, *viz.*, "the firm hold on essentials and its corresponding elimination of 'frills.' I recognize and admire the book's closeness to experience. It tells what its writers have found reliable in the years of their intimate contact with patients."

Beginning with a short chapter on historical aspects of tuberculosis, the reader accompanies the patient through the steps incident to his first visit to the doctor's office, the taking of the personal history, the physical examination, the diagnosis, and the treatment.

Modern methods used in diagnosis and treatment are described, including the roentgenological examination, the significance and importance of the tuberculin test in diagnosis, laboratory methods, pneumothorax, and other forms of compression and collapse therapy. Respective chapters are assigned to the subject of heliotherapy and the part climate plays in the treatment of pulmonary tuberculosis.

After having surveyed the results of various attempts by physicians and others in different parts of the world to produce a serum, vaccine, or drug as a specific treatment for pulmonary tuberculosis the authors conclude "it is evident that the long looked for specific drug, vaccine, or serum which will have a specific curative effect on tuberculosis is still as elusive as in the days of Robert Koch."

Separate chapters are devoted to pulmonary tuberculosis in childhood with special reference to its significance, pulmonary tuberculosis in the aged, diet, rehabilitation, the heart in pulmonary tuberculosis, questions relating to marriage and pregnancy among the tuberculous, dangerous trades, and finally a chapter on the prevention of tuberculosis.

The reviewer suggests more recent reference for the chapter on Rehabilitation of the Tuberculous, a phase of the community control of tuberculosis which has been greatly neglected in the past.

For completeness a brief summary and selected references for supplementary reading follow the majority of the chapters, and throughout the book are well considered diagrams, charts and X-ray reproductions.

Public health administrators also will find this book of interest and of value for ready reference purposes.

BERNARD S. COLEMAN

A Textbook in Physiology—*By William D. Zoethout, Ph.D. (5th ed.) St. Louis: Mosby*, 1935. 694 pp. Price, $4.00.

Since 1916 this splendid text has

gone through 5 editions. The present one has been extensively rewritten, and chapters on material concerning which modern research is bringing such rapid changes have been brought up to date.

This book is definitely an effort to reach the happy medium between the extensive and intensive text needed by students and specialists in medicine, and the much briefer and often too elementary short texts in physiology.

Following brief chapters on Protoplasm, Enzymes, Tissues, and the "Translocation of Matter" the author discusses the usual divisions of physiology. The practical side of physiology has been kept in mind, and the chapters on nutrition, physical exercise, mental work, and fatigue are good bases for personal hygiene guidance.

Certain chapters are headed by lists of related subjects with page references to the text. This is a decided help in giving students the concept that body parts and "systems" are definitely interrelated. CHARLES H. KEENE

BOOKS RECEIVED

THE CHILD OF THE TEXAS ONE-TEACHER SCHOOL. By Annie Webb Blanton. Study No. 17, Bureau of Research in the Social Sciences, The University of Texas Bulletin, Austin, Tex. 111 pp.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Diphtheria in Large Cities—Again evidence is presented that where diphtheria immunization is practised consistently, diphtheria deaths and morbidity drop. Though diphtheria death rates in the large cities were lower in 1935 than in 1934, there are far too many preventable deaths from this cause.

ANON. Diphtheria Mortality in Large Cities of the United States in 1935. J.A.M.A 106, 24:2060 (June 13), 1936.

Less Typhoid Fever—In the annual compilation of typhoid fever deaths in the largest cities of the United States is shown a gratifying reduction during the year 1935 as compared with 1934. All sections except the South Atlantic and the Western groups showed decreases.

ANON. Typhoid in the Large Cities of the United States in 1935. J.A.M.A. 106, 23:1983 (June 6), 1936.

They Still Go Unvaccinated—At this college, 33 of each 1,000 students admitted never having been vaccinated. Those with scars gave an immune reaction in 75 per cent of cases; those with history of vaccination but no scar revealed 35 per cent immune reactions, while only 5 per cent of those never vaccinated were immune.

BULL, R. C., and RANKIN, S. L. Smallpox Immunity in 5,000 College Students. Pub. Health Rep. 51, 23:734 (June 5), 1936.

What Can Health Do for Safety?—Pleading for public health participation in highway accident prevention, this Canadian author points out the opportunities for the experimental method of preventive medicine in establishing causes and testing control measures.

BURNETTE, N. L. Death in Safety Week. Canad. Pub. Health J. 27, 6:267 (June), 1936.

New Field for Nurses—Summary of the way various countries are using the nurse in commercial aviation and in the development of air ambulances.

CARTER, M. L. The Nurse and Aviation. Internat. Nurs. Rev. 10, 2:118, 1936.

Interviewing the Midwife—Leading questions by which supervising nurses may evaluate midwives' services are discussed.

DERRYBERRY, M., and DANIEL, J. The Development of a Technique for Measuring the Knowledge and Practice of Midwives. Pub. Health Rep. 51, 24:757 (June 12), 1936.

Toward Preserving Public Health—Another excellent paper on the economics of public health. (We have had several lately.) The author quotes the remark that, though the horse can be led to water but not made to drink, still it is possible to make him thirsty. Health education is the way to make the public thirsty for health. A dispassionate view of medical economic problems ends the paper.

EMERSON, K. Health Security. New Eng. J. Med. 214, 24:1211 (June 11), 1936.

Nursing for a Community—Nursing service for a community, to be adequate, must be based upon a satisfactory program of nursing education that prepares nurses not only for hospital service but for the varied health and sickness needs of the community. Suggestions are made for setting up necessary machinery for distributing this service, so that it will be available according to the needs of the individual

and family, rather than according to his ability to pay.

GOODRICH, A. W. The Community Nurse. Ohio Nurses Rev. 11, 2:78 (Apr.), 1936.

Difficulties in Polio Prophylaxis—Accepting the hypothesis that the virus of poliomyelitis enters the body through the olfactory tract, and migrates intracellularly through the nervous system to the cord, where it makes the tissue resistant to reinfection, and that only then does it escape to excite antibody formation in the blood, it is probable that artificially induced antibodies are not necessarily a measure of nerve tissue resistance.

HUDSON, N. P., *et al.* Factors of Resistance in Experimental Poliomyelitis. J.A.M.A. 106, 24:2037 (June 13), 1936.

Antirachitic Milk Values—Relative potency of vitamin D, as it affects human infants, and as found in the various commercial vitamin D milks is the subject of this report, presented in two installments. Its object is to aid physicians, health workers, and milk producers alike.

JEANS, P. C. Vitamin D Milk. J.A.M.A. 106, 24:2066 (June 13), 1936.

Eugenics vs. Cancer—Controlled experimentation with mice reveals definite information about hereditary factors which influence development of cancer. But human nature, being what it is, there is little chance of putting this information into practical use.

LITTLE, C. C. The Present Status of Our Knowledge of Heredity and Cancer. J.A.M.A. 106, 26:2234 (June 27), 1936.

All about School Child Health—What the school teacher and the school nurse may do to make their combined efforts a satisfactory health education program for school children, leads this series of excellent articles on school hygiene.

WHITNEY, A. Team work in School Health Education. Pub. Health Nurs. 28, 6:372 (June), 1936.

BEATTY, W. W. Sex Education in the Public School. p. 376.

CLINE, L. V. The Nurse in the Modern School. p. 380.

CHAYER, M. E. Changing Conceptions of School Nursing. p. 385.

PLEASANT, F. J. A New Deal for the Preschool Child. p. 393.

Tuberculosis among Nurses—Incidence of tuberculosis among nurses employed in tuberculosis sanatoria is reviewed, with valuable recommendations on ways to minimize the hazard.

MARIETTE, E. S. The Tuberculosis Problem among Nurses in a Tuberculosis Sanatorium. Am. J. Nurs. 36, 6:605 (June), 1936.

Cheerful Findings about Heart Disease—In this Canadian study it was found that 75 per cent of heart deaths occurred in people over 60, and that the percentage of later deaths is increasing. The average age at death grows greater, and hence the causes of death must change.

OILLE, J. A. The Problem of Heart Disease in Adults. Canad. Pub. Health J. 27, 6:261 (June), 1936.

Home Emergency Care of Postpartum Patients—Describes the procedure used in giving hypodermoclysis to postpartum patients in the home to prevent shock from hemorrhage and to replace fluids lost through dehydration.

PERRY, H. Hypodermoclysis for the Post Partum Patient in the Home. Am. J. Nurs. 36, 6:588 (June), 1936.

Milk Improvement in England—This discussion of the "accredited herd" program in Great Britain will be of interest to American sanitarians who are concerned with the improvement of our milk supply, not so much because of new proposals, but as a comparison with this country's problems.

RABAGLIATI, D. S. The Accredited Producers' Scheme of the Milk Marketing Board. Pub. Health. 49, 9:310 (June), 1936.

Home of General P. G. T. Beauregard on Chartres Street—The fine example of New Orleans Colonial architecture, home of the Confederate hero, is now being saved as a shrine for his relics and Civil War records by a group of New Orleans patriots under the leadership of Gen. Allison Owen.

THINGS IN NEW ORLEANS YOU WILL WANT TO SEE

THE Sub-Committee on inspection trips has arranged a tentative program for the Annual Meeting of the American Public Health Association, which embraces visits to the New Orleans Water Purification Plant and a survey of the sewerage and water systems of New Orleans.

The Sewerage & Water Board, which is a non-political board, was organized and began to function in 1899. Before that time rain water collected in wooden cisterns and the raw Mississippi River water were the only sources of drinking water in the city. At that time the water was obviously not very pure or clean.

The following table will give an idea of the improvements which have resulted in the water supply since the formation of the Sewerage and Water Board.

The water purification station, which has been copied in the essential details by several municipalities around New Orleans, is a model type of the rapid filtration systems generally in use for turbid waters.

The Purification Plant is reached readily in 20 minutes from the center of town and transportation will be provided, with the coöperation of the Sewerage and Water Board, for those desiring to visit the plant, where competent guides will explain the technical details which are necessary to put out the very satisfactory water which is furnished the City of New Orleans.

There are 28 filters with a total filtering area of 40,068 sq. ft. When operated at rated capacity, they are capable of filtering 112 million gallons of treated water per day.

	Before Treatment (Miss. River Water)	*After Treatment* (N.O. Tap Water)	*Maximum Allowed Under U.S. Public Health Standards*
Physical Characteristics (Parts per million)			
Turbidity	600	0.5	5.0
Color	10	5	20
Odor	Earthy	0	0
Chemical Characteristics (Parts per million)			
Calcium (Ca)	38	15	..
Magnesium (Mg)	8	6	100
Iron (Fe)	0.03	0.015	0.3
Zinc (Zn)	..	.03	5.0
Lead (Pb)	..	.001	0.1
Copper (Cu)	..	.05	0.2
Sulphate (So4)	42	44	250
Chlorides (Cl)	16	16	250
Total Solids	850	150	1,000
Bacterial Characteristics (1934)			
B. Coli per 100 ml.	1,940	0.06	1.0

This particular trip should prove of interest to all attending the Convention, and especially to the Laboratory and Public Health Engineering Sections.

In addition to providing water, the board is responsible for the adequate drainage of the city, and the achievement of this objective has been one of the triumphs of science in New Orleans.

New Orleans, as a whole, is below high water in the Mississippi River, which borders it on one side, and the greater portion of it is also below high water in Lake Pontchartrain, which bounds it on the north, and high water in the navigation canals and high level outfall drainage canals, which extend into or through the city. The city depends for its protection on the great levees along these waters, and the further judicious operation of the Bonnet Carré Spillway built by the United States Government at Bonnet Carré, La. As compared with mean tide level, the various portions of the city range from, say 14 ft. above to 3 ft. below mean tide, and extreme high lake tides are, on rare occasions, as much as 5 ft. above mean tide, and the highest water in the river reaches over 20 ft. mean tidal level.

From the above, it is evident that New Orleans depends on pumping for the removal of all the storm water and sewage which has to be removed.

The pumps used both in the sewerage and drainage work were especially designed by the engineer in charge of the Sewerage and Water Board Power and Pumping Stations; the drainage pumps being of very unusual size and high efficiency, and the sewage pumps combining very high efficiency with the ability to pump any kind of trash which enters sewers without any tendency to become obstructed thereby.

It might be said that pumps modeled after the pumps referred to are in use in Holland, Calif., and various other places. Their inspection and explanation alone would amply repay any visitor interested in mosquito eradication by drainage or in the salvage of marsh lands for agricultural purposes.

A third function of the Sewerage and

Water Board is the disposal of sewage. The sewage, consisting of polluted waste water from houses, factories, etc., is collected in a system entirely separate from the system of pipes and canals that receive the surface water or storm drainage. House connections, 76,306 in number (serving about 110,000 premises), and nearly all 6″ in size, conduct the sewage into 653.7 miles of sewers. More than 556 miles of these are 8″ in size, others are larger; the largest main sewer is of brick, 7′ in diameter. There are 9,236 manholes giving access to these sewers.

The sewerage system covers about 652 miles of streets and receives the sewage of about 110,254 premises with the scattering of population over very wide areas.

Eight first-lift pumping stations lift the sewage on its way to the main pumping stations, and, in three cases, a second lift pumping station is needed before the final discharge stations can be reached, making 11 intermediate stations in all. These are all electrically driven and automatically operated, without any screening of the sewage or any attendance other than periodic visits to see that all is well.

Four final discharge stations A, B, and D, on this side of the river, and C in Algiers, pump the sewage through cast iron discharge mains into the Mississippi River well down stream, whence the continuous flow of the river soon brings it to the Gulf. These too, are electrically driven, and operate without screening of the sewage, but attendants are constantly on duty.

In the 11 intermediate stations there

The Conciergerie—Old New Orleans—Combined entrance and janitor's quarters—only conciergerie in the United States—of the original Ursuline Convent on Chartres Street; built in 1727, Mississippi Valley's oldest building. Through these gates "Les Filles a Cassette" passed.

are 27 pumps having a total capacity of 306,180,000 gallons per day. In the 4 final discharge stations there are 15 pumps having a total capacity of 528,768,000 gallons per day. Pumping Station A, alone (the largest of the sewage pumping stations) pumps 17,000,000,000 gallons in a year, enough to make a lake 10′ deep, covering an area of over 8 square miles. Even this vast quantity of water is lost in the immensity of the flow of the river; the sewage never reappears at the surface; and no test made further down stream has ever indicated its presence in the river water.

Another trip of particular interest which has been arranged, will require approximately a day for its accomplishment, and to which will be attached a small cost, is a visit to the National Leprosarium at Carville, as well as a visit to the State Capitol at Baton Rouge, with its marvelous capitol building.

Located in New Orleans also is one of the finest hospitals of the U. S. Public Health Service, the Marine Hospital, which is located next to Audubon Park, one of our most beautiful places of interest in the city. It is thoroughly modern and from a standpoint of handling imported communicable diseases, will amply repay any visit made by health officers or others.

It must not be forgotten that New Orleans has located on its west bank a very modern Quarantine Station, where the most efficient methods of gaseous disinfection are carried out. The officer in charge of the station at present has gained world-wide note for his constant research for improvement in the use of hydrocyanic gas in the disinfection of vessels which come into port and require treatment.

There are many canneries of syrup and seafoods located in or near the city which should offer an attractive exhibit of modern methods in the handling of the most important industry of food canning.

The laboratories devoted to rodent control are operated continuously, and in view of the interest in endemic typhus and the other members of the Rocky Mountain spotted fever group, as well as bubonic plague, offer an opportunity for those unacquainted with the methods used for rodent examination to make a study of the subject.

A particular matter of interest, which is an object lesson of the value of drainage, and which is a great source of pride to New Orleanians, is the reclamation of the marsh area just behind the shores of Lake Pontchartrain, which has resulted in the creation of one of the largest and most beautiful parks in the world, the New Orleans City Park, as well as the creation of a park area and future residential district, where before only swamps existed, and in the erection of one of the finest airports in the world, if not the finest.

Many other inspection trips of in-

St. Louis Cathedral—The site of this old church was laid out by Bienville when he founded New Orleans in 1718; the present church is the third to occupy the grounds. It was built in 1796.

Madame John's Legacy—This building dates back to the days before the Louisiana Purchase (1803) when the colorful Dons of Spain imposed upon the resentful Creoles of Louisiana an obnoxious government.

terest for those of special trend are available and ample facilities for transportation will be provided.

Space does not permit any further statement, at this time of the points of interest in New Orleans, but the visitor may be assured that every effort will be exerted to make available for him all places of sanitary, as well as historical interest, and anyone contemplating visiting New Orleans, who is interested in any particular subject, is invited to write in advance to the Chairman of the General Committee of Arrangements, Dr. J. M. Batchelor, New Orleans, La., in order that the desires of the writer may be satisfied when he visits New Orleans.

ASSOCIATION NEWS

Recommended Change in the Constitution and By-Laws

THE Committee on Constitution and By-laws, acting on a suggestion made at a meeting of the Governing Council in Milwaukee, has recommended a change in the Constitution to provide that all members of the Executive Board will automatically be members of the Governing Council, thus obviating the confusion which has sometimes occurred. Some members of the Executive Board have been able to attend meetings of the Governing Council only by sufferance, although they were charged with acting for the Council during the intervals between Council meetings. The first paragraph under Article III Governing Council, therefore would read:

A. Composition: There shall be a Governing Council consisting of:

1. The officers of the Association and the elective members of the Executive Board.

Nominations for the Governing Council

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that " upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing such petition is received fifteen days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Milwaukee will be elected for the three year term 1936–1939.

G. F. Amyot, M.D., D.P.H.
Health Unit

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Charles F. Blankenship, M.D., 302 Marine Hospital, New Orleans, La., Assistant Surgeon, U. S. Public Health Service, with Regional Consultant, 4th District

Anthony S. Culkowski, M.D., City Hall, Lackawanna, N. Y., Health Officer

Charles P. Drury, M.D., City Hall, Marquette, Mich., Health Officer

John E. Dunn, Jr., M.D., Rm. 204, Federal Office Bldg., San Francisco, Calif., Assistant Surgeon, U. S. Public Health Service

Oswald F. Hedley, M.D., Maloney Bldg., University of Pa., Philadelphia, Pa., Passed Assistant Surgeon, U. S. Public Health Service

Frederick W. Kratz, M.D., State Health Dept., Bismarck, N. D., Passed Assistant Surgeon, U. S. Public Health Service

Samuel B. McPheeters, M.D., Health Dept., Goldsboro, N. C., Director, Wayne County Health Dept.

Robert A. MacTaggert, 4 Nott Terrace, Schenectady, N. Y., Acting Health Officer

William L. Orr, M.D., Ozark, Ala., Health Officer, Dale County Health Unit

Hermon B. Smith, D.V.M., P. O. Box 71, Farmville, N. C., Health Officer

Michael J. Sullivan, M.D., 66 W. Main St., Meriden, Conn., City Health Officer

Russell E. Teague, M.D., C.P.H., 306 Guthrie Bldg., Paducah, Ky., Health Officer

Laboratory Section

Lewis W. Brown, M.D., 160 Roseville Ave., Newark, N. J., Pathologist, Essex County Hospital for Contagious Diseases

John M. Dannecker, 1425 Lesseps St., New Orleans, La., Chemist, City Board of Health

Isaac H. Erb, M.B., 67 College St., Toronto, Ont., Canada, Pathologist, The Hospital for Sick Children

Anne G. Irwin, 519 Dexter Ave., Montgomery, Ala., Bacteriologist, State Dept. of Health

Raymond A. Kelser, Ph.D., D.V.M., Army Medical Research Board, Ancon, C. Z.

Walter H. Nolan, 63 Old Harbor St., S. Boston, Mass., Volunteer Assistant, Bacteriological Laboratory, City Health Dept.

James E. O'Brien, 545 W. 111 St., New York, N. Y., Chief Bacteriologist, W.P.A.

Monroe A. Rosenbloom, M.D., 1100 Park Ave., New York, N. Y., Senior Clinical Assistant Gynecologist, Out-Patient Dept., Mt. Sinai Hospital

Morris Scherago, D.V.M., University of Ken-

tucky, Lexington, Ky., Head, Dept. of Bacteriology

Public Health Engineering Section

Louis A. Cornelius, 2089 Robinson Rd., Grand Rapids, Mich., Member, Advisory Committee, Local Health Dept.

Clare H. Currie, C.E., Webster City, Ia., Consulting Sanitary Engineer

Benjamin L. Grimes, Jr., Box 933, Juneau, Alaska, Territorial Sanitary Engineer

Horace G. Tuggle, 440 Reese, Memphis, Tenn., Director, Sanitation and Malaria Control, Shelby County Health Dept.

Industrial Hygiene Section

Norman DeNosaquo, M.D., 219 Butler Ave., Providence, R. I., Student, Harvard School of Public Health

Charles C. Dills, 2028 New Hampshire St., Lawrence, Kans., Industrial Hygiene Engineer, State Board of Health

Joseph J. Eller, M.D., 745 Fifth Ave., New York, N. Y., Consulting Dermatologist

Donald O. Hamblin, M.D., Calco Chemical Co., Inc., Bound Brook, N. J., Chief Physician

Harry J. Johnson, M.D., Life Extension Institute, 25 W. 43 St., New York, N. Y., Chief, Examining Staff

Masayashi Yamaguchi, M.D., Dept. of Public Health, Yale Medical School, New Haven, Conn., Student

Child Hygiene Section

Elizabeth I. Adamson, M.D., 67 Park Ave., New York, N. Y., Consultant in Psychiatry

Emilio de Soto, M.D., Harriet Lane Home, Johns Hopkins Hospital, Baltimore, Md., Student

Nathan E. Silbert, M.D., C.P.H., 19 Goodale Rd., Mattapan, Mass., Student, Harvard School of Public Health

Public Health Nursing Section

Rocia Dority, R.N., Box 404, Canton, Ga., Field Consultant Nurse, State Dept. of Health

Jose Familar, Central Luzon Agricultural School, Nueva Ecija, P. I., Supervising Teacher of Hygiene and Sanitation, Bureau of Education

Bessie P. Hanson, R.N., 743 Sixth Ave., Troy, N. Y., Executive Secretary, Rensselaer County Tuberculosis and Public Health Assn.

Leeta A. Holdrege, R.N., 301 City Hall, Omaha, Nebr., Executive Director, Visiting Nurse Association of Omaha

Hetty I. Joach, Rm. 302, Court House, Jefferson City, Mo., County Public Health Nurse

Alice N. Jones, 42 N. Sheridan Ave., Indianapolis, Ind., Supervisor of School Nurses, Indianapolis Board of Health and Charities

Louise J. Keiber, 428 E. 133 St., New York, N. Y., Supervising Nurse, Mott Haven Health Centre

Martha J. Long, Heber Springs, Ark., County Health Nurse

Sadie E. McCarty, R.N., 708 Walnut, Fall River, Mass., Supervisor of Nurses, Board of Health

Clarina H. Morier, R.N., 759 Merrimack, Lowell, Mass., School Nurse, Board of Health

Ethel F. Murray, Hotel Aragon, Madera, Calif., Health Supervisor, Madera County Dept. of Education

Ethel Phillips, 115 E. Church St., Elmira, N. Y., Director, Visiting Nurse & Tuberculosis Assn.

Irma E. Reeve, 35 Elm St., New Haven, Conn., Associate Director, Visiting Nurse Assn. of New Haven

Emma E. Roberts, 332 Boston Place, Toledo, O., Director, Toledo District Nurse Assn.

Lila Sallee, Pocahontas, Ark., Public Health Nurse, Randolph County

Virginia D. Virgin, R.N., State Health Dept., Charleston, W. Va., Associate Director, Bureau of Venereal Diseases

Mary A. Ward, 3209 Delachaise St., New Orleans, La., Field Supervisor, Child Welfare and Community Health Assn.

Blanche Webb, 300 W. York St., Norfolk, Va., Director, The King's Daughters Visiting Nurse Assn.

Public Health Education Section

Embree G. Jaillite, 30 Rockefeller Plaza, New York, N. Y., Director of Publications, Public Health Committee of the Cup and Container Institute

Donald S. Lacroix, 25½ Pleasant St., Amherst, Mass., Hygiene Teacher, Amherst High School

Jacob A. Salzmann, D.D.S., 9915 Herrick Ave., Forest Hills, N. Y., Director, Dental Service, New York City Vocational Schools, Board of Education

Justin J. Shapiro, 707 Broadway, Paterson, N. J.

Epidemiology Section

Dr. Jose A. Lopez del Valle, Linea 78, Habana, Cuba, Director of School Sanitation, Finlay Institute

Roscoe L. Mitchell, M.D., 10 Burleigh St., Waterville, Me., Assistant Director, State Bureau of Health

Aurang Shah, M.D., C.P.H., P. O. Box 211, Boston, Mass., Student, Harvard School of Public Health

Unaffiliated

Harold Abramson, M.D., 1097 Madison Ave., New York, N. Y., Medical Inspector, and Field Epidemiologist, Bureau of Child Hygiene and Bureau of Preventable Diseases, New York City Dept. of Health

George F. Cottle, M.D., U.S.S. Pennsylvania, San Pedro, Calif., Medical Officer, U. S. Fleet

Luis Mazzotti, M.D., Huasteca 311, Mexico City, Mex., Student, School of Hygiene, Johns Hopkins University

Mary C. Raymond, 3307 Prytania St., New Orleans, La.

Howard Weinstein, 358 Ellsworth Ave., New Haven, Conn., Student, Dept. of Public Health, Yale School of Medicine

DEATHS

Jules Constantin, M.D., D.P.H., Roverval, P. Que., Elected Member 1933

Gertrude M. DeWitt, Chicopee, Mass., Elected Member 1920

Andronique Lafond, M.D., D.P.H., Parisville, P. Que., Canada, Elected Member 1933

Leslie Wentzel, Scranton, Pa., Elected Member 1922

CLOSING DATE FOR FELLOWSHIP APPLICATIONS

THE Committee on Fellowship and Membership wishes to announce that September 1 is the closing date for accepting Fellowship applications for action at the New Orleans Annual Meeting. Eligible members who desire to apply for Fellowship this year are requested to submit their applications to the committee as much in advance of September 1 as possible.

ASSOCIATIONS MEETING WITH A.P.H.A. AT NEW ORLEANS

THE following meetings of other associations will be held in New Orleans October 20–23, 1936, at the same time as the Sixty-fifth Annual Meeting of the American Public Health Association.

American Association of School Physicians
American Association of State Registration Executives
Conference of State Laboratory Directors
State Conference of Sanitary Engineers
Association of Women in Public Health
International Society of Medical Officers of Health

NEWS FROM THE FIELD

ANOTHER PUBLIC HEALTH AWARD GOES TO NEW YORK STATE

AT the 51st Annual Conference of the State and Provincial Health authorities of North America, held in Vancouver, B. C., June 22–24, 1936, a testimonial was presented to the New York State Department of Health. The awarding of this testimonial indicated, in the opinion of the Grading Committee, that the staff of the New York State Department of Health had in 1935 done more to develop an interest in the Health Conservation Contests than the staff of any other state department.

A testimonial on the above basis is given annually by the United States Chamber of Commerce. Dr. Arthur T. McCormack, State Health Officer of Kentucky, a member of the Health Conservation Contest Committee, made the presentation, and in the absence of Dr. Edward S. Godfrey, New York State Health Commissioner, Dr. John A. Ferrell accepted the testimonial. In making the presentation, Dr. McCormack stated that, in his opinion, in conducting these Contests the United States Chamber of Commerce and the American Public Health Association had undertaken one of the most inspiring public health activities. The Health Contest for cities and rural communities had already resulted in a great deal of publicity and, through the interest of the chambers of commerce, business men have had their attention definitely directed to the importance of public health. Business men and employers of labor had been impressed in a manner unknown hitherto, and were coöperating in programs for health betterment. The Contests have been the means of putting into actual practice many of the ideas and principles which health workers have discussed, but had never been able in whole or in part to convert into concrete public health advances.

Dr. Ferrell, in accepting the award, stated that New York State, with its large and complex population, had unusual public health problems, but, notwithstanding all this, it compared most favorably with other states in its solution of its problems, and in advances along public health lines. The interest shown in the Contests indicated that the state was ready to give time, thought, and effort to them because they were a specific aid in health promotion.

CRIPPLED CHILDREN DEPARTMENT IN NORTH CAROLINA

THE North Carolina State Department of Health has established a Department for Crippled Children in coöperation with the Children's Bureau of the U. S. Department of Labor, in the administration of the Social Security Act.

Objectives outlined in the bulletin of the health department are to locate crippled children, of whom it is estimated there are about 20,000 in the state; to obtain expert diagnosis in all parts of the state; to provide expert treatment and hospital care; to establish a field of supervisory service and follow-up service, and to engender public interest in the problem of the crippled child.

INDIANA APPOINTMENTS

THE following changes in Health Officers in the Indiana Division of Public Health have been announced:

Dr. Elmer D. Johns, of Zionsville, succeeding Dr. Lawrence S. Bailey as town Health Officer.

Dr. Camden G. Bothwell, of Martinsville, succeeding Dr. George B. Breedlove as Health Officer of Morgan County.

Dr. James L. Denaut, Health Officer of Hamlet.

Dr. Clyde J. Munns, of Newburgh, succeeding Dr. John T. Samples as Health Officer of Warrick County.

CANCER CAMPAIGN IN MAINE

A STATE committee has been formed to carry on a campaign against cancer which was recently launched under the auspices of the American Society for the Control of Cancer, the State Board of Health of Maine, and the Maine Medical Association.

The committee, of which Dr. Magnus F. Ridlon, of Bangor, is chairman, will provide free services of a pathologist, a radiologist, a roentgenologist, and a surgeon.

A woman's "field army" against cancer has been organized; and clinics have been established at Lewiston, Waterville, and Portland.

DIABETES CAMPAIGN IN OHIO

THE Public Health Federation of Cincinnati has recently formed a special committee on diabetes in coöperation with the Academy of Medicine of Cincinnati, with Dr. Cecil Striker as chairman.

The committee plans to establish an information bureau for physicians and the public, to make a study of the morbidity and mortality of diabetes, and to carry on public health education.

AUTOMOBILE VACATIONS

NEARLY 37 million persons in 11 million automobiles took vacations by motor in 1935, says the American Automobile Association.

AUTOMOBILE INSPECTION IN CHICAGO

SINCE July 1, all owners in Chicago, Ill., are required to have their automobiles inspected. This compulsory inspection is expected to reduce accidents by eliminating mechanical defects, and to lessen noise in the city.

Every automobile registered in Chicago must have an inspection twice a year.

CONNECTICUT HEALTH BULLETIN CELEBRATES FIFTIETH YEAR

THE *Connecticut Health Bulletin* celebrated its fiftieth anniversary with the May issue.

The May *Bulletin* reproduces various covers and pages from its earlier issues. The first number appeared in June, 1887, and it has been printed continuously since that time.

MME. IRENE JOLIOT CURIE HONORED

IRENE JOLIOT CURIE, daughter of the discoverers of radium, has been named Undersecretary for Scientific Research in the recently organized cabinet of the French Government.

Madame Joliot Curie, who from her childhood collaborated with the late Madame Curie in her research, shared the Nobel Prize in Medicine in 1935 with her husband, Frederic Joliot, for their work on radium.

PNEUMONIA RESEARCH GRANT

THE Commonwealth Fund of New York has approved an annual grant of $16,800 to the Michigan State Department of Health, Lansing, to promote study of antipneumococcic serum and to reduce the cost so as to make it available to the person of ordinary means. It will continue three years or longer, if sufficient progress is shown. . . . Last year the death rate from

pneumonia in Michigan was the highest since 1929.—*J.A.M.A.*, July 18, p. 219.

EVANSTON WINS SAFETY PRIZE

IN the Fourth National Traffic Safety Contest, sponsored in 1935 by the National Safety Council, Evanston, Ill., won the grand prize for the second time. Its motor death rate was 2.9 per 100,000. The national average for all cities of all population groups was 18.1.

MENTAL HYGIENE EXAMINERS APPOINTED

UNDER the provisions of a law passed by the 1936 legislature establishing a board of qualified examiners in the New York State Department of Mental Hygiene, the following have been appointed to constitute the board:

Dr. Frederick W. Parsons, Commissioner of Mental Hygiene

Dr. Vernon C. Branham, of Woodbourne, appointed by the Commissioner of Correction

Dr. Lloyd H. Ziegler, of Delmar, appointed by the Superintendent of Education

Dr. Israel Strauss, of New York, selected by the Medical Society of New York.

The code of criminal procedure has been amended to require that courts appointing a commission to examine persons charged with crime include at least one qualified psychiatrist.—*J.A.M.A.*, July 11, 1936, p. 137.

FLORIDA MATERNAL AND CHILD HEALTH BUREAU

A BUREAU of Maternal and Child Health in the Florida State Department of Health, Jacksonville, Fla., has been established. Dr. Emile Bryant Woods, Assistant Professor of Obstetrics and Gynecology, University of Georgia School of Medicine, Augusta, Ga., has been announced as the Director.

The new bureau will act in an advisory capacity to city, county, and district health departments, and will sponsor a statewide educational program. It was made possible through funds provided under the Social Security Act.

NETHERLANDS ANTIVENEREAL DISEASE CAMPAIGN

IN the conduct of an antivenereal disease campaign, each country selects a method in keeping with the national character. This explains why in the Netherlands the organization of this campaign is imbued with a spirit of independence and of hatred for coercive measures.

In place of official examinations of the genitalia of prostitutes and the compulsory registration of those infected, a policy based on persuasion and free will has been instituted. This operates through therapeutic stations open during the evening hours. The work of the stations is supplemented by consultation offices and by the coöperating services of women social workers who visit the infected women undergoing treatment.

It is the same approach that has been used with notable success in the fight on tuberculosis. In addition, propaganda against the venereal diseases is carried on through lectures, moving pictures and so on. The results in big cities such as Rotterdam have been most encouraging. — *J.A.M.A.*, July 18, p. 226.

BIRTH CONTROL GROUP ORGANIZED

THE National Medical Council on Birth Control was organized in June, 1936, for these purposes:

1. To control and supervise all medical policies of the American Birth Control League.
2. To initiate, encourage, and execute appropriate scientific research in the medical aspects of birth control.

The Executive Committee of the

Council is as follows: Frederick C. Holden, M.D., Chairman; Eric M. Matsner, M.D., Executive Secretary, member A.P.H.A.; Eliot Bishop, M.D.; A. N. Creadick, M.D.; Foster Kennedy, M.D.; Edgar Mayer, M.D., member A.P.H.A.; Richard N. Pierson, M.D.; Owen Toland, M.D.; Wilbur Ward, M.D.; and Prentiss Willson, M.D.

Headquarters of the National Medical Council on Birth Control are established at 515 Madison Avenue, New York, N. Y.

INSANITY OF WAR

PSYCHIATRISTS warn the world against the surrender of civilization to the insanity of war.

The Netherlands Medical Association, at The Hague, sponsored a document signed by 339 psychiatrists from 30 nations, in which they warn the statesmen of the world against unleashing the "destructive instincts which break loose as soon as the community feels itself threatened by danger."

NEW YORK'S CHILDREN'S CAMPS MUST REGISTER

IN a further effort to safeguard the health of New York City children, the New York Department of Health is requiring every agent, or agency, representing out of town camps for children to register detailed information with the Sanitary Bureau. This includes: a complete description of the camp's sanitary arrangements; description of the source of its milk supply; data on how many children are housed—what examination of food handlers is made before employment—whether the camp is operated under a State permit—whether or not the camp has a resident physician—whether or not a trained nurse is employed, and so forth.

Section 217a of the Sanitary Code provides that—

. . . All agencies in the City of New York taking children out of town to camps on vacation periods of more than one day shall register annually with the Department of Health of the City of New York through an authorized executive of such agency, stating the name, location and post office address of the camp, name of the director, the license number of the previous year and whether the camp is inspected by the Department of Health of the State where located.

While the majority of out of town camps operating out of New York City are licensed by the respective States, occasionally one is found not to have this protection.

HAY FEVER STUDY

A CHEMICAL study of substances in agricultural products and by-products that contribute to the allergic disturbances—hay fever, asthma, hives, and related afflictions—is being established in the Bureau of Chemistry and Soils of the U. S. Department of Agriculture, it has been announced.

One-tenth of the population of the country suffer seasonal distress or continual discomfort and restricted activity as the result of allergic diseases known by such familiar names as hay fever, pollen fever, rose fever, rose colds, asthma, hives, and so on. These afflictions affect people of all ages. Some individuals suffer from abnormal sensitiveness to certain normal constituents of the pollens produced by many varieties of trees, grasses, and weeds. Similar substances present in common foods, textile fibers, furs, and other farm products are also capable of causing distressing disturbances when absorbed through the skin or the membranes of the respiratory or digestive systems of supersensitive persons.

Chemists and specialists in other lines of scientific investigation will attempt to isolate these offending components and to determine their composition. Dr. Henry Stevens, biochemist of the Protein and Nutrition Division of the Bureau of Chemistry

and Soils is organizing the staff which will undertake the allergen investigation.

SILICOSIS PREVENTION

WHILE expressing gratification over the coöperation of employers in complying with the provisions of the silicosis prevention provisions of the industrial dust-hazard acts which became effective this month in New York State, State Industrial Commissioner Elmer F. Andrews today cautioned employers against final commitment, acceptance, and installation of dust-collecting and eradicating machinery before such machinery had been formally approved by the State Industrial Board.

Commissioner Andrews announced that he would immediately appoint an Advisory Committee to make a comprehensive study of machinery and methods and rules and regulations for the prevention of dust disease hazards, this committee to make recommendations to the Industrial Board which would take final and formal action. He called attention to the fact that the law requires the installation of approved dust-removing devices at the earliest opportunity, but also pointed out the danger of installing machinery which might later fail to meet official approval. While awaiting the action of the Industrial Board on various devices now being manufactured, the Commissioner admonished every employer to " take every reasonable precaution to reduce the dust hazard in his plant."

PERSONALS

WILLIAM H. PARK, M.D., F.A.P.H.A., Biggs Professor of Preventive Medicine and Director of Bacteriological Laboratories, New York University College of Medicine, has been granted a leave of absence for the session 1936–1937, and will retire after that period. Dr. Park has been connected with the University since 1895. He was Professor of Bacteriology and Hygiene from 1900 to 1933, when he received his present title. In the session of 1914–1915 he was Dean of the School of Bacteriology and Hygiene.

Dr. Park, for many years Director of the Department of Laboratories of the New York City Department of Health, reached the retirement age for that position December 20, 1933, but his term was extended, and was again extended June 5, to September 30.

ROBERT H. HAZEMANN, M.D., member A.P.H.A., has recently been made " Chef du Cabinet Technique " of the Ministère de la Santè publique. This is the first time that a secretary with public health training has been appointed.

CHARLES W. MCDONALD, M.D., member A.P.H.A., formerly Director of County Health Work of the Alabama State Department of Health, has been named head of the Gadsden County Health Department, recently organized, with headquarters in Quincy, Fla.

FRANK WINFIELD LAIDLAW, M.D., F.A.P.H.A., of Middletown, N. Y., formerly a District State Health Officer, has been provisionally made District Health Director of the New York State Health Department.

JOHN L. JONES, M.D., member A.P.H.A., of Medina, Ohio, has been appointed Special Investigator in the Bureau of Child Hygiene of the Ohio State Department of Health. He will make a detailed investigation of maternal deaths, in coöperation with the Hospital Obstetric Society of Ohio.

DR. ROBERT V. BOYCE has been named Acting Superintendent of Health of Hartford, Conn., succeeding Thomas F. O'Brien, M.D., member A.P.H.A., who was granted a leave of absence.

VERA H. JONES, M.D., member A.P.H.A., of Denver, Colo., has been named Director of Maternal and Child Health and Care of Crippled Children, under the Colorado State Board of Health and the Social Security Administration.

SAMUEL WEISSROSS, M.D., member A.P.H.A., has been appointed Director of the Bannock County Health Unit, Pocatello, Idaho.

HERBERT A. MCCLURE, M.D., member A.P.H.A., is Health Officer of the newly formed Health Department in Taylor County, with headquarters in Perry, Fla.

CHARLES HOWE ELLER, M.D., DR.P.H., member A.P.H.A., of Charlottesville, Va., has resigned as Health Officer of Albemarle County, to become Assistant Director of Rural Health with the Virginia State Health Department.

DR. JAMES R. KINGSTON, of Deer River, Minn., has been appointed Health Officer of the Northern District of Minnesota, with headquarters in Bemidji. The district is composed of Koochiching, Itasca, Hubbard and Beltrami Counties.

DR. ALICE HAMILTON, of Boston, Mass., F.A.P.H.A., technical adviser on industrial poisons, U. S. Department of Labor, was presented with the National Achievement Award of the Chi Omega Sorority, June 22.

ELLEN C. POTTER, M.D., member A.P.H.A., Director of Medicine of the New Jersey Department of Institutions and Agencies, received the honorary degree of doctor of laws at the annual commencement of the New Jersey College for Women, New Brunswick, N. J., June 6.

MILLARD E. WINCHESTER, M.D., F.A.P.H.A., of Brunswick, Ga., Health Officer of Glynn County, was presented in Superior Court, June 29, with a set of resolutions passed by the grand jury acknowledging his service and that of his staff in achieving national recognition for the Glynn County Board of Health in the Health Conservation Contest sponsored by the U. S. Chamber of Commerce and the American Public Health Association.

JAMES F. EDWARDS, M.D., member A.P.H.A., has retired as head of student health service and the Department of Hygiene, Iowa State College, Ames, Iowa, and is succeeded by Dr. John G. Grant, his assistant for several years.

PHILIP DRINKER, member A.P.H.A., has been promoted from Associate Professor to Professor of Industrial Hygiene, at Harvard University School of Public Health, Boston, Mass.

DR. RICHARD E. SHOPE, of the staff of the Princeton laboratory of the Rockefeller Institute for Medical Research, received a prize of $1,000 awarded by Sigma Xi on the occasion of its semicentennial in June. The award was made in recognition of Dr. Shope's work on swine influenza.

BENJAMIN G. HORNING, M.D., of the Connecticut State Health Department, has been named Superintendent of the Hartford Board of Health.

DR. WILDRIDGE C. THOMPSON, JR., who recently received the Certificate in Public Health at Johns Hopkins University, has been appointed full-time Medical Consultant in Social Hygiene in the New York State Department of Health.

DR. HELEN H. OWEN, of Albany, N. Y., has been provisionally appointed Assistant Director of the Division of Maternity, Infancy and Child Hygiene in the New York State Department of Health. She was formerly on the staff of the Division of Laboratories and Research.

DR. LLOYD A. MASTERSON, of Opelou-

sas, La., for 2 years Director of the St. Landry Parish Health Unit, has been promoted to Director of the Bureau of Maternity and Infant Hygiene of the Louisiana State Board of Health. Dr. Franklin V. Boyd, member A.P.H.A., of Lake Providence, succeeds Dr. Masterson as Health Officer.

DR. WILLIAM DOCK, Associate Professor of Medicine, Stanford University School of Medicine, San Francisco, Calif., has been appointed Secretary of the San Francisco Heart Committee, to succeed Dr. Amos Christie, who has resigned to engage in a two-year study at Johns Hopkins University Hospital for the U. S. Children's Bureau.

DR. WILLIAM BLAIR HUNTER, of Gastonia, N. C., has been appointed Health Officer of Harnett County.

DR. WILLIAM J. DONALD, of Lafayette, Ala., has been named Health Officer of Baldwin County, to succeed Dr. Stephen A. Durick, of Bay Minette, resigned.

RUTH HAY, who has been Assistant Professor of Public Health Nursing at Western Reserve University, has accepted a position as Director of the Course in Public Health Nursing in the School of Nursing at the University of California, Berkeley, Calif.

DR. WILLIS D. GILMORE, of Tombstone, Ariz., has been appointed Tuberculosis Consultant of the Department of Health of Arizona.

DR. JACK B. EASON, of Tucson, Health Officer of Pima County, Ariz., has been placed in charge of the new health unit in Yuma County.

DR. LEWIS C. ROWLES, of Clearfield, Pa., has been appointed Medical Director of Clearfield County, to succeed Dr. Horatio L. Woodside, of Bigler, member A.P.H.A., resigned.

DR. CHARLES E. LYCHT, Assistant Professor of Medicine and acting chief of student health, University of Wisconsin Medical School, Madison, Wis., has been appointed Professor of Health and Director of Physical Education for Men at Carleton College, Northfield, Minn.

DR. LOUIS TUFT has been appointed to succeed Dr. John L. Laird as head of the laboratory in the Pennsylvania State Department of Health.

DR. WILLIAM D. JENNINGS, JR., of Augusta, Ga., has been appointed to the newly created position of Police and Fire Surgeon.

DEATHS

DR. ARTHUR JACOB WOLFF, of Hartford, Conn., died June 22, at the age of 81 years. He was a bacteriologist in the Hartford Health Department for 32 years.

CLINTON T. MESSNER, D.D.S., chief of the Dental Department, U. S. Public Health Service, since 1924, died in Washington May 28.

CONFERENCES AND DATES

Aug. 2–8, Annual Meeting, National Institute for Commercial and Trade Organization Executives, Northwestern University, Evanston, Ill.

Aug. 11–14, American Veterinary Medical Association, Deshler-Wallick Hotel, Columbus, Ohio

Aug. 16–22, National Medical Association, Philadelphia, Pa.

Aug. 16–22, Annual Convention, National Hospital Association, Philadelphia, Pa.

Aug. 17–18, American City Planning Institute, Cambridge, Mass.

Aug. 18–20, League of Iowa Municipalities, Davenport, Iowa.

Aug. 19–21, Annual Meeting—Central States Section, American Water Works Association, Hotel Cleveland, Cleveland, Ohio

Aug. 22, National Conference on Pharmaceutical Research, Dallas, Tex.

Aug. 24–25, American Association of Colleges of Pharmacy, Dallas, Tex.

Aug. 24–29, Symposium on the Environment and Its Effect Upon Man, at the Harvard University School of Public Health, Boston, Mass.

Aug. 24–29, American Pharmaceutical Association, Dallas, Tex.

Aug. 28, Twelfth Annual Convention, California Dietetic Association, Fairmont Hotel, San Francisco, Calif.

Aug. 29–Sept. 6, Third Postgraduate Course of the International Hospital Association, Prague, Czechoslovakia.

Aug. 31–Sept. 5, Second International Medical Week, Lucerne, Switzerland, sponsored by the *Swiss Journal of Medicine*.

Aug. 31–Sept. 12, Harvard Tercentenary Conference of Arts and Sciences, Cambridge, Mass.

Sept. 1–4, Annual Conference, Governmental Research Association, Ann Arbor, Mich.

Sept. 2–4, Annual Convention, National Shade Tree Conference, Hotel Statler, Boston, Mass.

Sept. 2–4, Annual Convention, Union of Nova Scotia Municipalities, Digby, Nova Scotia.

Sept. 2–4, Annual Meeting, Ontario Municipal Association, Toronto, Ont.

Sept. 7–10, International Union Against Tuberculosis, Lisbon, Portugal.

Sept. 7–11, Sixtieth Anniversary Meeting, American Chemical Society, Pittsburgh, Pa.

Sept. 7–12, Third World Power Conference, National Power Policy Committee, Department of the Interior Building, Washington, D. C.

Sept. 9–12, Annual Meeting, American Forestry Association, Hotel Lakeside, Eagles Mere, Pa.

Sept. 14–17, Annual Convention, League of California Municipalities, Santa Monica, Calif.

Sept. 14–17, Annual Meeting, California Sewage Works Association, Santa Monica, Calif.

Sept. 15–30, First International Congress of Sanatoria and Private Nursing Homes; Margitsziget, Sanatorium, Budapest, Hungary.

Sept. 21–23, Annual Convention, American Institute of Park Executives and the American Park Society, South Bend, Ind.

Sept. 21–23, Annual Meeting, Rocky Mountain Section—American Water Works Association, Denver, Colo.

Sept. 22–25, Annual Meeting--New England Water Works Association, Pennsylvania Hotel, New York, N. Y.

Sept. 23–25, Annual Meeting of the New York State Association of Dairy and Milk Inspectors, Van Curler Hotel, Schenectady, N. Y.

Sept. 23–26, Mississippi Valley Conference on Tuberculosis, The Mississippi Valley Sanatorium Association, Hotel Pere Marquette, Peoria, Ill.

Sept. 24–25, Annual Meeting, League of Wisconsin Municipalities, Manitowoc, Wis.

Sept. 28–30, Public Works Congress—American Society of Municipal Engineers—International Association of Public Works Officials, Toronto, Ont.

Sept. 28–Oct. 1, American Society of Municipal Engineers, Toronto, Ont., Canada.

Sept. 28–Oct. 2, American Hospital Association, Cleveland, Ohio

Sept. 28–Oct. 2, American Association of Port Authorities, San Francisco, Calif.

Oct. 1–3, Southern Tuberculosis Conference, Hot Springs, Ark.

Oct. 5–9, Annual Safety Congress and Exposition, National Safety Council, Atlantic City, N. J.

Oct. 6–12, Fire Prevention Week.

Oct. 9, 10, New York State Sewage Works Association, Geneva, N. Y.

Oct. 10–18, National Dairy Show, National Dairy Association, Dallas, Tex.

Oct. 12, 13, Canadian Dental Association, Montreal, Que.

Oct. 12–15, Annual Convention—Southwest Section, American Water Works Association, Fort Smith, Ark.

Oct. 12–17, The Dairy Industries Exposition, Atlantic City, N. J.

Oct. 12–18, Third International Congress on Malaria, Madrid, Spain.

Oct. 14–16, Annual Convention, Pennsylvania Water Works Association, Haddon Hall, Atlantic City, N. J.

Oct. 14–17, Annual Civil Service Assembly of the United States and Canada, Cincinnati, Ohio.

Oct. 17–25, Centennial Exposition Dairy Show, Atlantic City, N. J.

Oct. 19–20, Conference of State Sanitary Engineers, New Orleans, La.

Oct. 19–21, Annual Meeting, International City Managers' Association, Richmond, Va.

Oct. 20–23 (Tues., Wed., Thurs., Fri.), Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Oct. 20–23, American Association of School Physicians, Hotel Roosevelt, New Orleans, La.

Oct. 20–23, American Association of State Registration Executives, New Orleans, La.

April, 1938, American Chemical Society, Dallas, Tex.

Positions Wanted

HEALTH OFFICERS

Young man, M.D. University of Tennessee Medical School; short course in public health at Vanderbilt University; 2 years' experience as director in a county health department; desires position as health officer. A-261

Physician, M.D. University of Maryland School of Medicine and C.P.H. Johns Hopkins University; nine years' experience as county and city health officer; desires position as director of a county or district with headquarters in a city. A-265

LABORATORY

Woman chemist, B.S. and M.S. degrees. Advanced work in food chemistry, nutrition and dietetics. Minor, bacteriology. Experience in analytical, organic and biochemistry. Desires position with hospital or commercial concern. L-259

Man, Ph.D. University of Wisconsin, several special courses in bacteriology, immunology, public health laboratory methods, etc.; 13 years' experience as assistant director in a state department of health laboratory and as Professor of bacteriology and hygiene at a university; desires position as bacteriologist. L-260

PUBLIC HEALTH ENGINEERS

Young man, graduate in engineering; several years' experience as director of a division of sanitation in a county health department; desires a position in public health engineering, administrative work preferred. E-250

Young man, graduate in civil engineering, University of Utah; post-graduate work in public health, Columbia University; 4 years' experience as sanitary engineer and supervisor of a health survey; desires position as assistant public health engineer. Available October, 1936. E-262

MISCELLANEOUS

Young man, M.D. Vanderbilt University; Sc.D. John Hopkins School of Health and Public Health; Dr.P.H. Harvard University; several years' experience as laboratory instructor and research associate; desires position as epidemiologist or teacher of public health and parasitology. M-263

Young man, S.B. Massachusetts Institute of Technology; 6 months' experience as assistant areal supervisor and engineer; desires position as field worker. Available now. M-264

Woman physician, M.D. Indiana University School of Medicine; 13 years' experience as the director of child hygiene in a state department of health, experience in adult education both as a teacher and administrator; desires position in health education or child hygiene. M-249

Woman physician, M.D. Boston University, Graduate work in health education in Columbia University and Massachusetts Institute of Technology; ten years' experience in child hygiene, psychiatry and with delinquent women; desires a position in school, college, child welfare or institutional work. M-248

Young woman, Ph.D. Columbia University; considerable experience in the field of health education with official, voluntary and commercial organizations; is interested in a position as Director of Public Health Education in a city, state or agency. *Available September 1. M-255*

Opportunity

Sanitary Engineer, to develop plumbing code and to direct plumbing inspection activities. Permanent tenure. Salary, $4,200 a year. For details, apply immediately to the Detroit Civil Service Commission, 15th Floor, Water Board Building, Detroit, Mich.

Persons with medical and post-graduate education who are seeking employment are invited to communicate with the Executive Secretary in regard to several available opportunities.

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

"Fine thing, the Telephone"

"HELPS TO KEEP PEOPLE CLOSE AND FRIENDLY"

"I put through a call for my son down East. Must be three hundred miles. 'Hold the line,' the operator said. And next thing you knew, there he was. Sounded just like he was right here. It wasn't like that when I was a young fellow."

THIS COUNTRY has the best telephone service in the world. And it's still getting better—quicker, clearer, more useful to more people. Each year brings improvements in equipment and operating efficiency. Operating errors on local calls—always a small percentage of the millions handled daily—have decreased 40% in the past six years.

Since 1929, the average time required for long distance connections has been reduced from 2.8 to 1.4 minutes and 92% of these calls are now handled while you remain at the telephone.

Time has proved the value of the Bell System plan of operation—"One policy, one system and universal service."

BELL TELEPHONE SYSTEM

Two new, quick diagnostic tests—

1—BRAHDY "RAPID CULTURE" TUBES

Lederle

FOR THE "RAPID CULTURE" DIAGNOSIS of Diphtheria. Identifies diphtheria infections within four hours! Based on a method originated by Folger; confirmed by Sole, tested by Brahdy and Brody (with modifications) in their work at the Willard Parker Hospital. Parish also confirms these findings.

Swabs are used to take nose and throat cultures, returned to the tubes and incubated for four hours. A physician's vest pocket serves as incubator. At the end of incubation period, smear preparations are made on slides directly from the swabs.

Available in packages of 12 swabs each, sealed in tubes and ready for immediate use.

2—TYPHOID GROUP ANTIGENS

Lederle

THESE ANTIGENS are stable over a period of six months; tests may be set up and read within a few moments; reports to physicians can be made the same day specimen is examined. Four antigens in 20 cc. vials covering Typhoid "O" and "H" and Paratyphoid A and B. Prepared acccording to the new method recommended by Welch and Stuart. Lederle outfit includes besides the antigens, 12 glass slides and polished wood slide container, bottle of wax mixture and loop for making wax rings.

Send for literature covering these two new diagnostics.

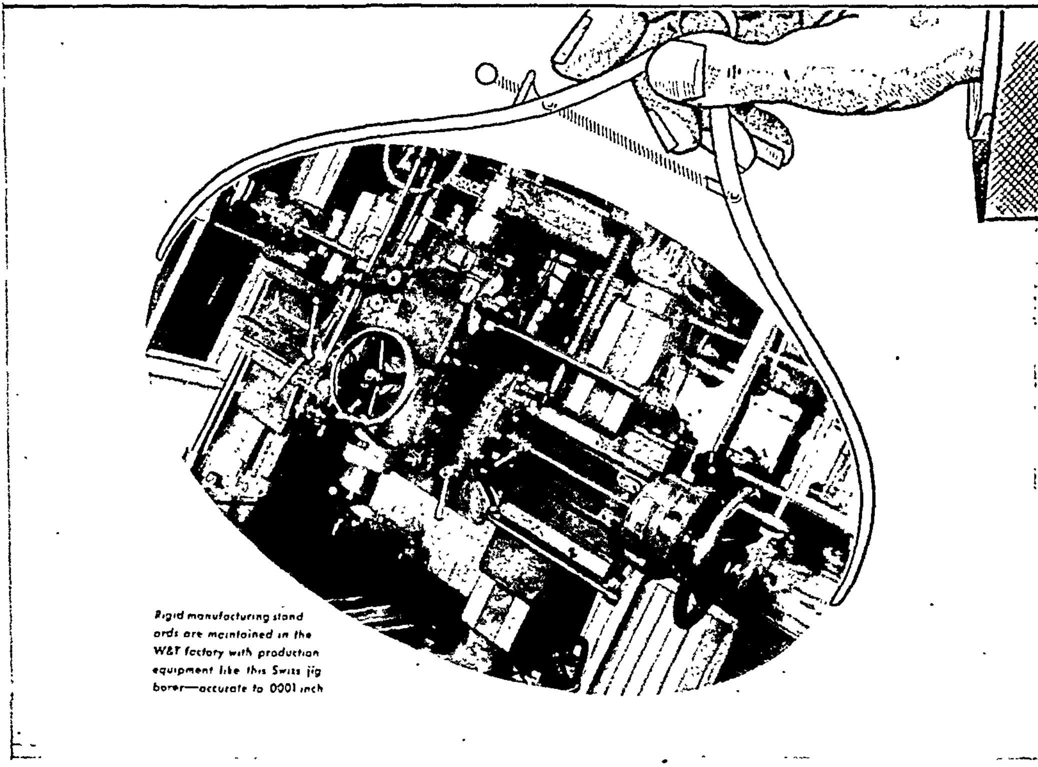
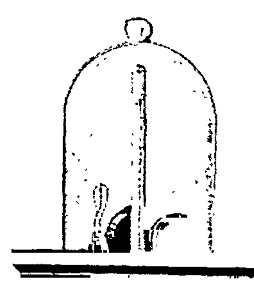
SAVING TOMORROW'S TAX DOLLAR



Rigid manufacturing standards are maintained in the W&T factory with production equipment like this Swiss jig borer—accurate to 0001 inch

THE CHLORINATION DOLLAR MUST BUY . . . UNIFORMITY



DAY AFTER DAY—tomorrow and years hence—every one alike. That's true of every part on a W&T Chlorinator,—it can be duplicated exactly tomorrow — or years from now.

Chlorination, especially of water or sewage, depends upon uniformity. Uniform results, unvarying health protection, can only be achieved with *uniform equipment. Standardize on W&T Visible Vacuum Control* for uniform accuracy, constant dependability and negligible maintenance expense. Standardized manufacturing methods, rigid inspection, continuous research and assured service all protect your investment

Tomorrow's taxpayers will be uniform in praising today's selection of W&T Visible Vacuum Chlorinators.

Health Work on a Sugar Plantation in Hawaii

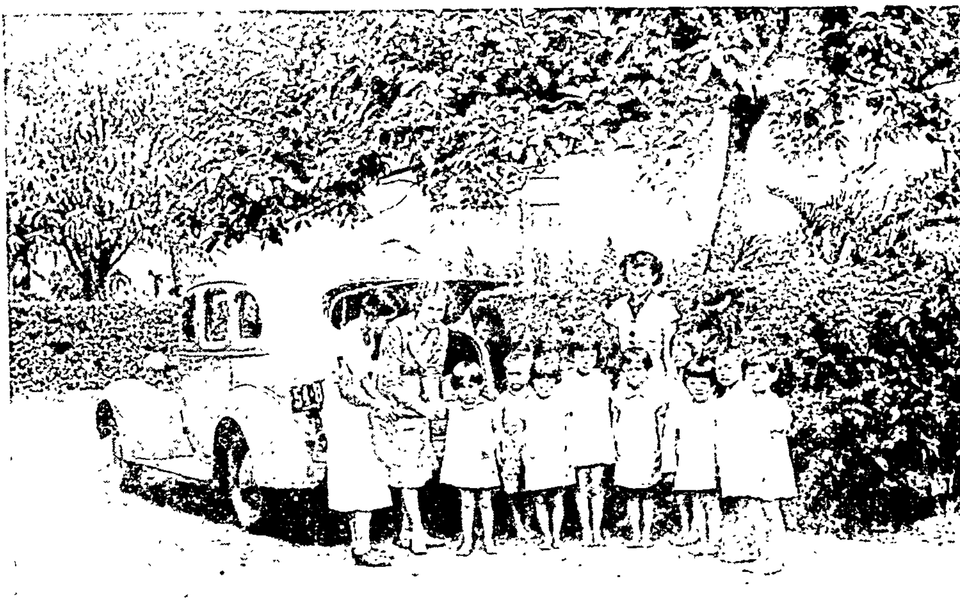
IRA V. HISCOCK, F.A.P.H.A. (*Life Member*)
Professor of Public Health,
Yale School of Medicine, New Haven, Conn.

HAWAII was blessed with many resources which enrich the life of her people; but the modern comforts and scientific benefits so abundantly provided are results of the vision, energy, and careful planning of community leaders. Although the Hawaiian Islands, in the mid-Pacific, are 2,000 miles from their nearest neighbor, California, they compare in progressiveness with the most advanced communities on the mainland. The sugar plantations render a valuable medical and welfare service which is gradually expanding to embrace the essential features of public health.

The achievements in the promotion of health and the reduction of preventable diseases are an illustration of the progress in Hawaii. The quality of medical practice is in general high, and excellent hospital and clinic facilities are available. Through the activities of the Territorial Board of Health, with the coöperation of many official and voluntary agencies, smallpox has become a medical curiosity; typhoid and tuberculosis have been greatly reduced; and diphtheria is well on the way to control. Over 60 per cent of the preschool children have been given prophylactic injections against diphtheria in this Territory of some 400,000 people, and there was not a death from this disease during the fiscal year 1934-1935. The tuberculosis death rate has dropped from over 200 in 1920 to an annual average of under 100 for the past 5 years. The infant mortality rate in the Territory was 65 for the fiscal year 1935, with an annual average rate of 82 for the previous 5 years. The average birth rate for the period 1929–1933 was 28. There is considerable variation in the birth and death rates according to race. Hawaii has become a "melting pot" of races and nationalities, as the islands are relatively free from racial prejudice, and natives and immigrants have intermarried, freely.

Hawaii is the first Pacific outpost of America's health defense, and public health work there is of extreme importance to the rest of the United States and to the Army and Navy forces.*

* On the island of Oahu are several important Army posts, including Schofield barracks, the largest Army unit in the United States, and an important Navy station at Pearl Harbor, adapted for expansion as needs arise.



A plantation visiting nurse inspecting children. The doctor and nurse advise the mother regarding diet, clothing and general care.

With the development of an air route to the Orient, bringing Honolulu within 17 hours of the mainland, our interest is stimulated.

PLANTATION SERVICES

Nearly half of the people in the rural sections of the islands (outside the cities of Honolulu and Hilo) and nearly one-third of the total population live on 39 sugar plantations. In 1934, there were over 105,000 employees and their families living in some 20,000 plantation houses. Each plantation employee receives free housing for himself and family, including water and fuel for domestic purposes, besides medical care and community services. The building programs of many plantations cover houses of the one-family type, with bathroom and flush toilet, each located on a lot sufficiently large for a vegetable garden and other home activities. Some $6,500,000 have been expended on new housing during the past 10 years, besides a similar amount for reconstruction of existing homes. Good living conditions and medical care are regarded as important and are reflected in the health and morale of plantation communities.

The employees and their families on each plantation constitute a distinct community. Almost all of the plantations own and operate modern hospitals with medical and nursing staffs. Those which do not have their own hospitals arrange for medical service with a hospital within a reasonable distance. The plantation physician is also appointed by the Territorial Board of Health as a government physician, and directs public health activities within the plantation community, besides serving as registrar of vital statistics and school physician for the district of which the plantation is a part. Each plantation submits a monthly health and medical record to the central office of the Hawaiian Sugar Planters' Association showing basic statistics of births, deaths from important causes,

cases of illness by principal causes, and medical and surgical services rendered. These data are summarized, and a tabular record is returned to the plantations.

As an example of the scale on which this work is carried on, in 1934, 8 plantations on Oahu having a population of 37,658 persons, spent for operating the free medical, hospital, and public health services a total of $206,927, in addition to $175,955 for sanitation and various other public services.

WAIALUA EXPERIMENT

On the invitation of the manager of the Waialua Agricultural Company, a special study of health conditions in the Waialua district was conducted during the summer of 1935.* This study illustrates the health problems of the plantations and opportunities for future development. It is customary for the plantations to conduct through the H.S.P.A. experiments for the improvement of business methods or of welfare conditions, such as housing, and for this purpose one or more plantations are selected. If an experiment on one plantation offers practical suggestions for advancement, the plan is generally adopted by the others. On the Waialua plantation, an experiment is in progress to determine the best methods of improving the economic and social conditions of the people in a typical rural district, so that these people will prefer to live in this rural district rather than in the city. The experiment is being conducted through a comprehensive organization of the community known as the Waialua Community Association, of which some 20 organizations in the district are members.

* Appreciation is expressed for the assistance received during the course of this study from John Midkiff, Manager, and Dr. A. L. Davis, Physician and Surgeon of the Waialua plantation, and from Dr. Frank Midkiff, Director of the Community Association.

The area of Waialua is about 200 square miles, the village being located in the center of a U-shaped coast line. The activities of the district are agricultural, the chief products being sugar cane and pineapples. In addition, there are incidental crops of bananas, vegetables, avocados, besides some raising of poultry and swine. There is considerable subsistence fishing off shore. The cane and pineapple lands are under corporate control. There is practically no homesteading or small farm ownership of these valuable lands, which constitute the basic natural resources of the district. Most of the water is similarly controlled, being both impounded in great gulch reservoirs and pumped from artesian wells.

HOSPITAL AND STAFF

The hospital has a capacity of 36 beds and includes a dispensary. The hospital staff consists of the plantation physician, 2 graduate nurses, one of whom spends about 80 per cent of her time in field visits (for welfare and public health purposes), a nursing assistant and interpreter, 5 attendants, and a clerk assistant. Two camp policemen make sanitary inspections in addition to the attention given to sanitary problems by the field nurse. Consideration is being given to the employment of another field nurse with special training in public health.

The Territorial Board of Health staff coöperates in the public health work of the plantation and provides nursing, baby conference, tuberculosis clinic, and inspection service for the outside area. The Department of Public Instruction directs health education and dental work in coöperation with the Board of Health.

THE PEOPLE

The people of the Waialua Agricultural Company represent approximately one-half of the population

TABLE I

POPULATION OF WAIALUA PLANTATION ACCORDING TO RACE, SEX, AND CHILDREN

Race	Total			Ratio Men to Women	Per Cent		
	Men	Women	Children		Men	Women	Children
Filipino	906	139	962	7:1	53	21	55
Japanese	516	313	382	1.6:1	30	49	22
Portuguese	119	105	195	1:1	7	16	11
Korean	42	29	96	2:1	2.5	4.7	5.5
Anglo-Saxon	40	31	45	1.3:1	2.5	4.8	2.5
Porto Rican	23	18	48	1.3:1	1.5	3.0	3.0
Others	38	15	30	2:1	3.5	1.5	1.0
Total	1,684	650	1,758	2.6:1	100	100	100

residing in the Waialua District. In the Waialua District as a whole, which is the fifth precinct of the fifth representative district, in 1930, there were 8,129 persons, of whom 5,210 (64 per cent) were males, and 2,910 (36 per cent) females. The plantation census as of June 30, 1934, showed a population of 4,461, of whom 3,310 were living in family groups and 1,151 were single. On the basis of 616 families, there were 5.3 persons per family. A total of 470 men, 248 women, and 1,797 children were classed as citizens.

The plantation census of February 11, 1935, revealed 4,092 persons in the villages of the company. Of these, 1,684 (41 per cent) were men, 650 (16 per cent) women, and 1,758 (43 per cent) children. The wives numbered 510.

The population was divided as to race as shown in Table I.

The public health problems of a

Plantation doctor and nurse receiving the laborers and members of their families at one of the village dispensaries.

community with the above composition are somewhat different from those of the average city, county, or district because of the large proportion of men of young and middle age, together with a fairly large number of young children.

The 1,066 houses on the plantation have an average of 2 bedrooms each, varying from 1 to 4. Most of the water supply is derived from artesian wells, with public connections to the houses. There are 38 cesspools, 90 septic tanks, and 880 privies. Plans for sewage disposal for the new homes are being developed in coöperation with the Territorial Board of Health. The milk supply is obtained from a tuberculin tested herd of a modern dairy, where consideration is being given to pasteurization.* Considerable canned milk is used by plantation families. Milk is furnished to laborers in the field during harvesting time, and to the schools and kindergartens.

HEALTH RECORD

During the years 1933 and 1934, there were 191 births in the district, of which 103 occurred among plantation personnel. During the first 7 months of 1935, 64 per cent of the plantation births occurred in hospital as compared with 50 per cent in 1934, and 42 per cent in 1933. Deliveries by an "informant," which were especially common among Filipinos, have shown a marked decrease in favor of hospitalization. But both the Filipinos and Japanese frequently employ midwives. For several years the plantation physician, the nurse, and the interpreter have stressed the importance of proper care at time of delivery, and

* It is noteworthy that 4 of the plantations on the island of Kauai have provided pasteurized milk for their employees.

their efforts are bearing fruit. The birth rate is very high among these families, one-third of the wives having been confined within a recent 19 month period, the proportion being nearly 50 per cent for the Filipinos and Porto Ricans.

Among the plantation population, during 1933 and 1934 there was an average of 24 deaths each year, 16 of which were of infants under 1 year of age.* Deaths of infants among Filipinos are abnormally high, due to causes associated with early infancy and feeding. In contrast, the Japanese, with a similar number of births, have a highly favorable rate. During 31 months, the infant mortality rate for the plantation was 85 (44 neonatal), the rate for the Japanese being 19; for the Filipinos, 185.

A study of the deaths from all causes on the plantation indicates that the leading causes which offer most opportunity for additional public health work are those related to early infancy, gastroenteritis, beriberi, pneumonia, and tuberculosis. The last two are problems of considerable importance among the laborers themselves, while the others relate to the health of their families and have both a direct and an indirect influence on the work of employees. The absence of deaths from acute communicable diseases of childhood since 1931 is noteworthy. There was no death of a child of school age from any cause during 1932–1935. Most of the preschool children have been given prophylactic injections against diphtheria and smallpox vaccination, and many of the plantation personnel have been given anti-typhoid vaccine. It is proposed to give anti-typhoid vaccine to families routinely upon employment. The problem of nutrition and feeding stands out prominently as a factor in the impressions gained from both morbidity* and mortality rates. Furthermore, in view of the health and welfare problems, consideration is being given to the furtherance of contraception and sterilization measures where indicated in individual cases.

Tuberculosis is recognized as an important industrial and public health problem, especially among the Filipinos and Hawaiians. In 1935, there were 35 known cases and 135 contacts among plantation personnel, with 12 new cases hospitalized. One of 2 chest clinics operated in the district is for plantation personnel. A tuberculosis survey of 7th grade school children was conducted in 1934–1935 in coöperation with the Board of Health. Of 200 children (chiefly plantation) given tuberculin tests, followed by X-ray examination of positive reactors, 1 was found to have tuberculosis and was admitted to the sanatorium. Two other children were classed as suspicious and placed under active medical and nursing supervision.

The plantation physician conducts laboratory work at the hospital, in addition to the examinations of milk and water and diagnostic specimens by the Territorial Board of Health.

Prenatal medical supervision is given to over half of the cases of pregnancy by the plantation physician who also conducts child health conferences at 3 camps. In addition, children are weighed at home in connection with nursing advisory visits.

There were some 1,600 school children in the entire Waialua district at the time of the 1934–1935 census. The plantation physician examines all entering school children each year, vaccinates any children not previously

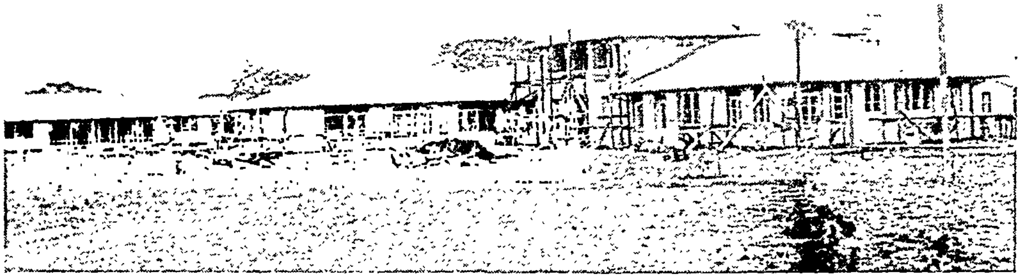
* In 1934, there were 6.1 deaths per 1,000 population, the rate for 38 plantations being 6.5. The rate for Filipinos was 9.1.

* In 1934, there were reported to the plantation physician 209 cases of communicable diseases, besides 36 cases of diarrhea and enteritis (23 under 2 years), 2 cases of beriberi, 25 cases of pneumonia, and 144 cases of other acute respiratory illnesses.

protected, and examines children referred by the teacher or nurse for special purposes. School nursing is rendered by the Board of Health nurse in the district.

SUMMARY

The Hawaiian Sugar Planters' Association and the individual companies recognized many years ago the value of attention to the health and welfare of the employees and their families. The Waialua Agricultural Company, Ltd., has studied the health, education, and welfare problems of the people living on the plantation with a view to future program planning. The people of the plantation are fortunate to have the benefit of a complete medical treatment program, including free diagnostic and hospitalization service. A new hospital will soon be erected, and the public health nursing service will be extended in coöperation with the Board of Health. Meanwhile a comprehensive education and recreation program is being developed in which health education will play a prominent rôle.



New sugar plantation hospital with modern facilities. Waialua Agricultural Company, Ltd.

Emancipation of Women

NOW may we turn to athletics and physical culture. For some years I have been investigating the effects of athletics on women and I am convinced of two things: (a) that physical exercise is as good for women as it is for men; (b) that excessive exercise is more harmful to women than to men. The difficult point to determine is where to draw the line. In recent years girls have been increasingly encouraged to take up different forms of exercise, and there is every indication that the Government intends to foster this movement. It therefore becomes increasingly important to have clear and definite ideas as to what is good and what is harmful. It must of course be axiomatic that nothing can be good for a girl's body which renders her less capable of motherhood. So far as I have been able to discover athletics are no more likely to cause heart trouble or any extra genital physical disability in women than in men. I am further of the opinion that exercise by itself has no harmful effect on childbearing. The idea that over-development of the abdominal musculature is disadvantageous is the direct contrary to the truth. The important points which remain to be determined are whether violent exercise exerts any effect on the development of the uterus or on subsequent fertility.—Geoffrey W. Theobald, M.D., Some Effects of Emancipation on the Health of Women, *J. State Med.*, XLIV, 6 (June), 1936.

Practical Methods of Testing for Mastitis

J. M. ROSELL, M.D.
Ministry of Agriculture of Quebec, Provincial Veterinary School, Oka, Quebec, Canada

"THE highly developed mammary organ of dairy cows is particularly liable to a number of diseases which are less common in the types of cattle in which selective breeding has not been so intensively directed toward udder refinement and functional capacity." "Streptococcic mastitis, the most common and formidable of udder infections, a chronic insidious and readily transmissible disease, usually results in serious permanent udder impairment." These quotations from Leunis Van Es tell nearly all we know of the etiological factors of the prevalent type of mastitis of cows.

The study of this important type of mastitis which affects approximately one-third of the actual milk production, begins with Nocard and Mollereau in 1884,[1] followed by workers from all countries where dairying is an important industry. The results presented in this discussion have been collected over a period of 10–15 years in Germany, Austria, Spain, and later in Canada and the United States. The author[2] presented the first description and report on this continent of *Strepto-cocci agalactiae* being found as the etiological agent of mastitis in Canada, together with the description of many of the methods actually used for the detection of this disease.

The publications on this disease during the last 10 years discussing its frequency, economic importance, diagnosis, etiology, prevention, and treatment are considerable. Of the more comprehensive studies of the disease, reference should be made to the work of Seeleman,[3] Klimmer and Haupt,[4] Rosell,[5] Whalley,[6] and recently Petersen and McCaster[7] containing a bibliography of more than 2,000 papers, Arne Hansen,[8] Hopkirk,[9] and also Steck.[10]

In this paper only a summary of the methods in general used for detecting the disease will be discussed.

The great number of publications on this question during the last 4–5 years, with diverse and opposing opinions, may bring confusion and cast doubt on the diagnostic value of the different tests proposed. In reality the diagnosis is not as difficult as might appear from the academic rather than practical discussions over the relative efficiency of these diagnostic methods. There may be some difficulty in understanding the etiological mechanism of this form of mastitis, but by the study of the physio-pathological or functional symptomatology there has been found the basis which permits the accurate diagnosis of nearly every case of the disease. This is accomplished by testing the function of the gland through the milk. Also physical examination affords the basis for an anatomical or clinical

diagnosis in very many cases if the infection is followed by anatomo-pathological changes, noticeable by expert manual palpation.

METHODS OF DIAGNOSIS

The following discussion deals with establishing the basis for an efficient diagnosis of every case of mastitis, since one of the main objects of the examination of cows from the public health standpoint is to detect every diseased, or better, every infected cow, which could be a source of infection for other animals or for man.

Three bases may be used for the diagnosis of pathological changes in the mammary gland, *viz.*, (a) the presence of the organism, which may be pathogenic for animals or men—this may not mean mastitis in the sense of considering as diseased only those cows showing clinical evidences; (b) the functional alteration which means secretion of abnormal milk, which ordinarily means mastitis in the ordinary clinical concept of the disease; (c) determination of the existence of anatomopathological changes perceptible by physical exploration which permits the detection of an anatomical form of mastitis, of the active type if accompanied by histological reactions. In other cases anatomical changes may be the cicatrices of a completely cured mastitis of no importance to public health or to farm prophylaxis; or else an idiopathic hypertrophy of the connective or mesenchymal tissue.

From the standpoints of public health and animal hygiene, which cannot be separated one from the other, the detection of the infection (a), as well as functional alteration (b), are the most important. The physical examination (c) is also a very important aid in diagnosis, if taken with its natural limitations. It should not in itself be accepted as a diagnostic procedure but should be considered in its relation to presence of infection and the secretion of abnormal milk.

RELATIVE VALUE OF DIAGNOSTIC METHODS

On reading the many publications on mastitis which have appeared in the last 4–5 years, it seems difficult to obtain a concrete opinion on the relative value of the methods of diagnosis from any of the concepts concerning mastitis, especially as to etiology, diagnosis, and therapy. Opinions of authors in this respect vary widely. This may be attributed in part to different findings, and to the possibility that different types of the disease may be present in different countries and circumstances. However, the results of the leading dairy bacteriological and veterinary institutions of this country and abroad are in complete or near accord, at least as to the diagnostic points of the disease. This concordance is especially obvious in the results of the institutions of the European countries, particularly those obtained in Germany, Switzerland, France, Austria, Scandinavia, and Denmark, where the problem of chronic streptococcic mastitis has been studied since 1910. These results are also very similar to those recently published by some important English, American, and Canadian institutions.

The estimate of the value of the various methods discussed in the present survey is based on results obtained in the above institutions in many of which the author has had the opportunity of working; and also on results secured during 8 years in this department and 4 months in the Bureau of Animal Industry in Washington, in cooperation with Dr. W. T. Miller.[11] The results confirm in most essential points those of the important milk institutions to which I have referred.

Bacteriological methods—Reference is made especially to the streptococcic or micrococcic forms of mastitis which

constitute the ordinary type of udder infection which are considered nearly exclusively in the mastitis campaigns at present going on in all countries. The more occasional infections of the udder (tuberculous, staphylococcic, colic, pyogenic, bacilloses, actinomytic, etc.), and also infections with the so-called *Streptococcus epidemicus* or beta hemolytic infection of the udder pathogenic for man, are not considered in this survey. The diagnosis of these is based upon the same methods or principles as those used for agalactiosis, or the *Streptococcus agalactiae* form of mastitis which, from a clinical standpoint, may often be present in an acute form.

Although in many cases the microscopic or cultural examination may be positive without other evidences of infection, the positive finding of the organism supposed to cause streptococcic mastitis or agalactosis should be one of the principal objectives of milk examination.

Besides the ordinary culture on blood or nutrient agar, some special methods are used for a better cultivation of *Streptococcus agalactiae* *i.e.*, the Klimmer serum-alkali-albuminate-saccharose brom-cresol purple agar plates [12]; Edwards [13] glucose 5 per cent serum agar containing 1:200,-000 crystal violet to prevent growth of staphylococci, or 0.1 per cent blood asculin 1 per cent Lenko agar containing crystal violet; or Bryan's [14] liver infusion broth agar containing 1:110,-000 brilliant green or gentian violet; and the Steck milk serum-dextrose deep agar method in special test tubes.[15]

For the technic of these methods and other questions of bacteriological testing, reference should be to the original papers or to other publications given in the attached bibliography. The author [16] earlier discussed many of these problems of testing for mastitis.

It should be stated here the Streptococcus connected with mastitis was first described by Nocard and Mollereau in 1884 [1] with all the precision that was possible at that time. Later, in 1890, it was described by Guillebeau and Hess,[17] and in 1894 as *Streptococcus agalactiae* contagion by Kitt.[18]

Since that time, the names *Streptococcus mastitidis* and *Streptococcus agalactiae* have been used interchangeably for this species of streptococcus. The characteristics given by Bergey [19] do not agree with those for 15 years universally accepted as typical for this streptococcus, which never ferments raffinose or inulin and very seldom mannitol; nor does it give a yellow surface fluid in litmus milk as stated by Bergey.

Cultural differentiation of *Streptococcus agalactiae* from closely related types is not difficult. The most important cultural characteristics of *Streptococcus agalactiae* or *Streptococcus mastitidis* are its ordinary flocculent aspect with clear supernatant media in lactose nutrient broth, and its non-beta hemolytic properties, and with generally an alpha, alpha prime, or gamma type of hemolysis. This streptococcus never produces a typical hemolysis of the washed blood corpuscles either under aerobic or anaerobic conditions, or the hemolysis in blood disk agar test described by the author, which consists of placing a small disk or piece of blood agar in a 15–18 hours old serum broth culture and incubating for 24 hours. In regard to hemolytic tests, the differences of opinion based on the work in different laboratories, may be due to the dissimilar technics and interpretations, as I have recently observed on a visit to many European institutions. Some even considered as a beta hemolytic those forming the smallest clear zone of less than a millimeter in diameter around colonies.

Other more important cultural char-

acteristics of *Streptococcus agalactiae* are a typical acid coagulation of litmus milk with sometimes a small reduction of the litmus at the bottom of the tube in 18–28 hours although ordinarily no reduction is apparent, no curdling of milk containing 1:20,000 of methylene blue; ability to hydrolyze sodium hippurate in 4–6 days; a final H-ion concentration of below pH 5.0 in glucose or lactose broth after 5 days, and a fermentation of sucrose, lactose, maltose, salicin; but not of mannitol, raffinose, arabinose, or inulin. These are the most important cultural characteristics which differentiate this type of bovine from all other streptococci. In a study of more than 400 strains isolated from separate quarters of diseased udders in Canada and at the Bureau of Animal Industry in Washington,[11] and in a comparative study of 208 strains of human, animal, and milk streptococci made at McGill University, it has been found easy to differentiate clearly between the *Streptococcus agalactiae* and other streptococci although strains giving some atypical cultural reactions were often encountered.

For the bacteriological test in mastitis, microscopic examinations of smears, especially those made from individual samples, aseptically taken and incubated, or, better, from centrifugated incubated samples, is often sufficient. The presence of leucocytes in numbers ranging approximately over 200,000 per c.c. of milk (1 in every 2 fields of 0.16 mm.) should make one suspect mastitis. This is in accordance with Udall and Johnson,[20] Ernst,[21] Hucker, Trudel, and Jennings.[22]

For streptococci to be found on a smear it is necessary that a relatively great number of chains be present in the milk, or that an impracticable amount of time be employed for their detection. In order to find a chain of streptococci in 100 fields, there must be, according to Steck,[15] at least 2,000 chains in 1 c.c. of milk. Culture offers a greater possibility of positive finding, but unfortunately streptococci are not detected by a single examination in all cases of streptococcic mastitis. The chances of culturing streptococci depend on the number present in milk and their biological condition. In using a loop of milk spread over an area of 2 mm., there should be at least 1,000 organisms in 1 c.c., all capable of growth in order to obtain 2 colonies and, in addition, the organisms must be equally distributed through the milk.

The etiological cause of the disease may not be found in diseased quarters on some days or periods of the disease, or even in some part of any single milking, and, in addition, they may be found occasionally in udders without any demonstrable functional or anatomical abnormality.

The functional diagnosis—The functional diagnosis, or the study of the physio-pathological alterations or disturbances is very much more efficient than the anatomical or even histopathological, diagnostic considerations.

In view of the fact that the functional diagnosis of mastitis, or the testing of its physio-pathological alterations or abnormalities, affords a more certain method of detecting the disease in its different degrees of intensity, than the anatomical examination does, this functional diagnosis should have preference, though the physical examination of the udder must not be neglected.

The detection of the inflammation of the udder through its functional disturbances by means of the many biological, chemical, physical, or physicochemical tests developed in the last 20 years, has the advantage of revealing the disease in many cases before the anatomical changes may be noticeable, at least by exterior examination, and even before histological changes may be perceptible. This functional diag-

nosis has also the advantage of measuring to a certain extent the degree of the disease, and even of approximating the border line between normal and pathological, which is still a matter of discussion. Also, only with the physiopathological diagnosis is it possible to differentiate between a carrier without mastitis and a diseased udder.

The functional diagnosis of mastitis is made by the determination of the abnormality of the milk or udder secretion; by testing the milk with test substances which will detect any change in its quantity and composition, depending upon whether the gland is normal or diseased or even in certain cases upon the general condition of the cow to which the gland gives a reflection as shown by Little and Jones.[23]

In mastitis not only is the quantity of milk reduced, but the quality is changed in chemical, biological and other aspects. The most commonly used tests for mastitis are based upon the determination of some of these alterations, the most important of which are given in the order in which we believe they can be most readily utilized for a practical and rapid diagnosis: (1) chloride increase detectable by field or laboratory tests; (2) catalase increase, detectable by field or laboratory tests; (3) decrease in H-ion concentration, detectable by field or laboratory tests; (4) cell increase, demonstrable by the leucocytic examination or by the microscopic sediment test; (5) diminishing of the sensibility to rennin, and appearance of soft curd; (6) presence of streptococci or pathogenic bacteria in incubated or non-incubated aseptically taken milk samples; (7) lactose decrease demonstrable by field or laboratory tests; (8) presence of clots as shown by the black cloth filter or strip cup tests; and (9) visible abnormalities or changes in the milk.

Other alterations in the milk which are not of as much practical importance for diagnosis are: fat decrease; effect on character and amount of casein; increase in heat coagulable albumin; decrease in solids not fat; decrease in specific gravity of serum; decrease in amount of ash; decrease in calcium and potassium; increase in sodium; decrease in electric conductivity; decrease in viscosity, and increase in per cent of water.

From the above outline we can see that milk substances elaborated by the glandular cells are decreased in the diseased udder, while those due to inflammatory reactions (chloride, leucocytes, catalases, etc.) are increased. The chemical and biological tests should be considered as more practical and effective for diagnosis than the bacteriological procedures.

All tests, especially the chemical and biological, give their best diagnostic results when employed on the milk of individual cows, preferably milk of separate quarters, and in fresh milk, except the chloride test which can be used in old milk.

Chemical alterations cannot be detected so well by studying the mixed milk of the 4 quarters as by testing the milk of each quarter, as frequently only 1 or 2 of the quarters may be infected. Because of this, diagnosis on mixed milk cannot be taken as definite. Although it is very important that the tests be carried out on the milk of each quarter separately by the use of certain tests, mastitis may be detected in some cases in mixed milk, if this milk contains approximately 10 per cent of milk from diseased udders.

One of those listed as the more efficient tests may suffice, if clearly positive, to establish the diagnosis, but no one alone is 100 per cent efficient, and the accuracy of the diagnosis increases by using simultaneously 2 or 3 tests.

Other biological and physico-chem-

ical tests have been given to differentiate normal from abnormal milk secretion as: freezing point depression; refractometer index; simplified molecular constant; and also, as a more or less indirect bacteriological test, the reductase test and certain serological tests, such as agglutination, complement test, etc. Many enzyme tests such as per cent of amylase, peroxydase, and the retarded rennet coagulation have been recommended.

For rapid and efficient work, the order in which it is recommended to proceed to test a herd for mastitis, including every quarter, is the following: (a) pH with brom thymol blue; (b) rapid catalase with 9 per cent hydrogen peroxide; (c) rapid chloride test, and after or before this test, (d) the black sieve cloth test, and (e) palpation and clinical examination of the udder.

With these 5 tests, but especially with the first 3, it is possible to find all, or nearly all, the diseased cows; and one person alone, or with a helper, may test in this way approximately 15 cows per hour.

After these tests, samples should be taken from the doubtful and such other cows as may be desired and more extended laboratory tests made. The comparative quantity of milk in different quarters by milking out and measuring should also be determined.

The samples for bacteriological examination should be taken aseptically, immediately cooled, and kept on ice. The technics for the tests, especially those of more practical value, as the pH, catalase and chloride, are given in a great number of other publications, and also have been summarized [14] in an earlier discussion.

The comparative value of the biological or chemical tests has been widely discussed with nearly unanimous agreement among many institutions, and dissent among many others.

These opinions can be summarized as follows:

The catalase and chloride tests are the most effective in finding cases of diseased udders according to function: we may say 98 per cent of the cases, if used simultaneously. The pH appears capable of detecting 80–85 per cent of diseased cows in some herds, especially if repeated on different days and hours, but in certain herds the per cent of detection by this method may be somewhat less.

With the simultaneous use of these tests, repeated if necessary in doubtful cases, it is possible to detect nearly 100 per cent of the diseased cows, even those only slightly diseased, although the exact border between the normal and pathologic has not yet been established.

The leucocyte count, and especially the bacteriological test, may give the lacking information in some special cases. The black cloth sieve test is useful only for cases where abnormal visible particles are present, which is not more than 10–20 per cent.

These tests may confirm the clinical examination or palpation test. Sometimes an abnormal palpatory finding, may be present without demonstrable infection. In these cases only the functional diagnosis can decide the existence of physio-pathological disturbance of the active disease.

The clinical or external examination—The importance of clinical examination is very great for many forms of mastitis. It includes history, all possible exterior examinations and observations on the general health of the cow, glandulary infarct, edema, local sensitiveness of the udder, and visible changes in the milk. Some changes in the milk can be detected by taste. The most important of all these clinical explorations is the skilled superficial and deep palpation after the quarters have been completely milked out.

The udder examination, although requiring more time because of the necessary emptying of the udder, should, if possible, be practised in every field test for mastitis.

The value of the physical examination is sometimes exaggerated, and it would do great harm for diagnosis and the detection of the greatest number of cases of mastitis if it were considered alone sufficient. Palpation should never be considered equal in diagnostic value to the combined bacteriological and biological tests or even alone, or to the biological or functional tests which are indisputably the most efficient methods of diagnosis at our disposal.

In the testing, during 8 years, of some thousands of healthy and diseased quarters, most of them examined physically at some time by the same principles of palpation used for many years in human medicine, the impression has been gained that it can never give the definite diagnosis obtained by biological and bacteriological testing. In studies carried on in the Bureau of Animal Industry with Dr. W. T. Miller,[11] 280 quarters were examined, of which 232 (82.8 per cent) were found to be abnormal. The number of quarters found to be diseased were positive to the individual tests as follows: chlorine test 192 (82.7 per cent), catalase test 167 (78.6 per cent), brom thymol blue test 69 (30 per cent) (in this case the pH value showed less efficiency than in many other circumstances); macroscopic and microscopic sediment tests 137 (69.5 per cent), palpation of the udder 151 (65.6 per cent), and the black cloth test 15 (6.0 per cent). Streptococci were present by only one examination in 94 (41 per cent) of the diseased quarters; they were also present in 10 (21 per cent) of the 48 quarters which failed to react to any of the tests, but in a second test many of these failed to show streptococci. This was the herd of a public institution where the mastitis and also the abortion have been prevalent for a long time.

SUMMARY

In view of the facts given, it is concluded:

1. The palpatory and clinical examination are not able to detect all the cases of mastitis.
2. The biological method of testing is the most accurate for the diagnosis of mastitis.
3. In consideration of the importance for the sanitation of a herd and for a successful campaign against mastitis, correctly used palpation and inspection, although very valuable, should be employed in conjunction with the biological and chemical and, if possible, bacteriological mastitis diagnostic tests.

American Sewerage Practice

". . . The twenty years which have elapsed since the publication of the second edition have witnessed some striking developments in sewage disposal. The activated sludge process, which was then in its experimental stage, has made great headway and now occupies a foremost place among methods of sewage treatment. The digestion of sludge in separate tanks is now widely practised, and forms the subject, particularly in America, of an enormous amount of research. Of late years there has been a marked revival of interest in the chemical treatment of sewage, and new modes of precipitation have been introduced which, though as yet in the experimental stage, have attracted favourable notice in many quarters.

In the course of the past twenty years the purification of sewage has made great strides in America. In 1915 only 3,900,000 people, 4¼ per cent of the population of the United States, lived in towns provided with sewage works. Treatment, more or less complete, is now given to the sewage of 20,000,000 of the people who inhabit cities having populations of 100,000 or over. From the point of view of the American engineer, the delay in putting schemes of sewage treatment in hand is not without its advantages. He starts with a clean slate, and he has the benefit of all the experience which has been gained in England and elsewhere. Usually too he has a free hand in the design of his works.

The sewage from 16,900,000 people is disposed of by dilution alone, and that from 8,500,000 by fine screening and dilution. The self-purification of polluted rivers has been closely studied in America, and seventy-five pages of the book are devoted to a consideration of the subject in all its bearings. Where sewage is discharged in the vicinity of bathing beaches or sources of water supply, chlorination is usually resorted to."—Excerpt from review in *J. Roy. San. Inst.* (Supp.), July, 1936, of *American Sewerage Practice*—Vol. III. *Disposal of Sewage*, by Leonard Metcalf and Harrison P. Eddy.

Adaptation of a Proposed Standard Methods Medium to General Bacteriological Culturing

Preliminary Report

C. S. BOWERS AND D. EVELYN WEST
Bureau of Laboratories, State Department of Health, Hartford, Conn.

THE desirability of using one simple, inexpensive, easily prepared, and readily available basic medium for different types of bacteriological culture work prompted the investigation of the suitability of a proposed Standard Methods milk medium.[1, 2, 3] This medium is composed of 0.5 per cent hydrolyzed casein—Tryptone,* 0.1 per cent glucose, 0.5 per cent fresh skim milk, and 1.5 per cent agar. Casein † and its various digestion products have been used previously in general culture media and for specialized studies of bacterial nutrition, toxin and indol production, and agglutination.

Separate studies were made to compare slight modifications of the proposed milk medium with special culture media in routine use for growing beta hemolytic streptococci, pneumococci and stock cultures and for some miscellaneous culture studies. Individual attention is given each of these subjects below.

BETA HEMOLYTIC STREPTOCOCCI

A comparison of the incidence of growth of beta hemolytic streptococci on tryptone blood agar and peptone beef extract blood agar plates was made with 553 swabs. The swabs used were those received routinely for examination of *Corynebacterium diphtheriae* with a request for an examination for beta hemolytic streptococci. The swabs were streaked first on the routine blood agar plates and then on the tryptone blood agar plates. After 18–24 hours' incubation at 37° C., the plates were examined for the presence of beta hemolytic colonies. Of the 553 swabs used, 113 (21 per cent) showed beta hemolytic colonies on the tryptone agar, and 95 (17 per cent) were positive on the beef extract agar. Seventeen swabs were positive on the tryptone and not on the beef extract, and 3 swabs were positive on the beef extract and not on the tryptone. One culture on the tryptone and 10 cultures on the beef extract were indefinite after 24 hours, and further incubation was necessary before complete hemolysis was observed. The colonies were of equal size on both media and the zone of hemolysis was equally clear.

For this study the original formula of the tryptone medium was modified by the omission of the skim milk and the addition of 0.5 per cent sodium

* Prepared by the Difco Laboratories, Detroit, Mich.
† See bibliography.

chloride. The routine medium was Standard Methods agar with 0.5 per cent sodium chloride. Both media were adjusted to pH 7.4 sterilized at 15 lb. for 20 minutes, and before use 5 per cent defibrinated sheep blood was added to each medium, and the poured plates were incubated 24 hours for sterility.

PNEUMOCOCCI

Specimens received for routine pneumococcus typing were streaked on one tryptone blood agar plate and one Douglas[20] blood agar plate and incubated 18–24 hours at 37° C. The plates were examined for numbers of colonies present, their size, and characteristic appearance. Both plates were then left at room temperature and the appearance of the colonies observed daily for 3 successive days.

The numbers of colonies appearing on both plates were comparatively the same. In several instances the colonies were slightly larger, and in some instances slightly more moist on the tryptone agar, colonies usually remaining more moist at room temperature a day longer.

Pure cultures of pneumococci inoculated into tryptone broth grew well enough in 6 hours to be used for Neufeld typing.

The tryptone agar was modified for this study by increasing the tryptone and skim milk content to 1 per cent each, adding 0.5 per cent sodium chloride, adjusting to pH 7.8. After sterilization 7 per cent defibrinated sheep blood was added, plates were poured, and incubated for sterility.

STOCK CULTURES

A group of 150 stock cultures were transferred from routine media to tryptone agar slants. These cultures had been carried on various media believed to be necessary for optimum growth of certain different species which do not grow readily in ordinary media. No modification of the original formula of the tryptone medium was made but the hydrogen-ion concentration was adjusted for certain fastidious organisms. Sub-cultures from stock cultures that had been stored in the refrigerator from 2 to 3 months were made, incubated at 37° C., and observed at 15, 24, and 48 hours. Good growth was observed after 15 hours, and luxuriant growth after 24, except in the case of one strain of *Proteus vulgaris* which did not grow well at 37° C., but which showed good growth at room temperature.

Following these preliminary observations the sub-cultures were placed in the refrigerator for 3 months, sub-cultured at the end of this period, and observations repeated. All cultures maintained their viability. The following 150 stock cultures were used: *Brucella melitensis* (6 strains), *Br. abortus* (14), *Br. Sui* (7); *Eberthella typhosa* (16); *Salmonella schottmuelleri* (6), *S. aertrycke* (5), *S. enteritidis* (6), *S. suipestifer* (1), *S. morgani* (3), *S. paratyphi* (1), *S. hirschfeldii* (1); *Shigella dysenteriae* (2), *Sh. paradysenteriae* varieties *Army, Flexner, Hiss, Strong, Harris, Sonne* (35), *Sh. alkalescens* (3), *Sh. dispar* (1); *Proteus vulgaris* (19), *P. hydrophilus* (1); *Bacillus anthracis* (1); *Serratia marcescens* (1); *Pasteurella tularensis* (1); *Escherichia coli* (1); *Pseudomonas aeruginosa* (1); *Actinobacillus mallei* (2); *Staphylococcus aureus* (2), *S. albus* (2), *S. citreus* (1); *Streptococcus stenos* (1), *Str. faecalis* (5); *Vibrio comma* (2); *Monilia candida* (2), and *Blastomyces* (unclassified) (1).

MISCELLANEOUS CULTURING

1. *Corynebacterium diphtheriae*—Tryptone broth (tryptone 0.5 per cent, glucose 0.1 per cent, fresh skim milk 0.5 per cent, pH 7.4) was substituted for the nutrient broth in Loeffler's blood serum medium and inoculated

with positive routine throat cultures of *Corynebacterium diphtheriae.* Luxuriant growth was obtained by overnight incubation at 37° C. and morphologically typical organisms were found upon microscopical examination.

2. *Neisseria intracellularis from a suspected case of meningitis*—Spinal fluid submitted for cultural examination was streaked on a tryptone blood agar plate as above referred to in the isolation of pneumococci and the plate was incubated at 37° C. for 24 hours. Typical colonies of *Neisseria intracellularis* were secured. Only one specimen of this type was available.

3. *Mycobacterium tuberculosis*—Six strains of *Mycobacterium tuberculosis* isolated from sputum in 1934 and kept at 37° C. for 13 months on a coagulated egg-yolk medium were inoculated on tryptone glucose skim milk agar slants and incubated at 37° C. Fairly good growth occurred in 5–7 days. Further work on the use of a modification of this medium for the culturing of *Mycobacterium tuberculosis* is being done.

4. *Antigens for Macroscopic Agglutination Tests*—The use of this medium for the production of antigens for use in macroscopic agglutination tests is also being studied and will be reported later.

SUMMARY

The proposed Standard Methods milk medium containing tryptone, glucose and skim milk proved excellent for use in general laboratory culture work. One hundred and fifty cultures of 37 types of organisms grew rapidly and abundantly. Organisms, such as brucellae, pasteurellae, meningococci, and pneumococci which usually are cultured only on special media were observed to grow rapidly on the tryptone medium with slight modification of nutrient material or adjustment of the hydrogen-ion concentration.

The use of digested casein products in bacteriological culture media has been known for several years, and while this simple basic medium is not presented as a solution for all the difficulties encountered in bacteriological culturing, it has been found suitable for many types of routine work as well as for milk plating. Its use eliminates the necessity of having divers media in stock, many of which are expensive and time consuming in their preparation.

Development of Leprosy Clinics in the Control of Leprosy

LEE S. HUIZENGA, M.D., DR.P.H., F.A.P.H.A.
Superintendent, Christian Reformed Mission Hospital, Jukao Ku, China

SPECIAL clinics for the modern treatment of those suffering from leprosy are comparatively new in our present-day public health programs. The slow development of these clinics is undoubtedly due to our antiquated attitude toward those suffering from leprosy. Such clinics can at present be developed only in the heart of some leprosy area, as no other place would bring sufficient patients, nor would any public health board allow such clinics to be opened except in such centers. Since leprosy patients are restricted in their movements in practically every country because of society's fear of the disease, it would become difficult even for a leprologist of international repute to start a special clinic in any land except where leprosy is prevalent. Suspected cases not yet definitely diagnosed, who have means wherewith to travel, may be able to visit such leprosy specialists as are found in Hamburg, Bergen, London, New Orleans, Calcutta, Honolulu, Manila, and elsewhere: but leprosy clinics of any size operated as public health control centers could hardly be expected to develop anywhere except where leprosy is prevalent.

TUBERCULOSIS AND LEPROSY COMPARED

The tuberculous patient in any stage of the disease is allowed to travel anywhere. Clinics and sanatoria are not limited to areas where tuberculosis is common. On the contrary, they are usually built where tuberculosis is not common, where the air is rare, where sunshine is plentiful. With the present attitude of society toward leprosy leprosy clinics and sanatoria are only found in leprosy infected areas. In this respect health boards and leprologists probably have still much to learn from those who specialize in tuberculosis. In the United States the states of Colorado, New Mexico, Arizona, and California, with their sparse population, are known for their tuberculosis clinics and sanatoria. Sufferers from all over the United States go to these sunshine states. The same is true of some mountain resorts in the east of the United States. This is not a public health measure to get infective cases out of populated communities, but rather a curative measure to get the best surroundings for the patients.

Such an arrangement might seem to be indicated for leprosy even more than for tuberculosis. Leprologists all over the world have observed that leprosy seems to limit itself to more or less definite sections. There are also areas where leprosy is not found. Just why it does not thrive in some areas is not known, yet this fact seems to be a sufficient reason to think of such areas as fit for the sanatorium care of leprosy. As far as the author knows, no leprosarium is built anywhere in an area known to be free from leprosy. Even

the United States Government has built its leprosarium in the only state where leprosy has been endemic for some generations. Would not some Rocky Mountain state suggest itself as a better location for its national leprosarium?

LEPROSY CLINICS IN HISTORY

In the past leprosy clinics developed at various places owing to varying local advantages. In Japan, for instance, a large leper clinic automatically developed near the hot sulphur springs about Kasatsu, as these springs not only are said to have curative qualities, but are found near the shrine of the lepers' god where hundreds of lepers go each year to pray for the return of their health.

Another group of sufferers gathered about persons reputed to have the ability to cure leprosy. The Old Testament priest had at least the authority to pronounce one clean, and the belief in the "royal touch," or the ability of kings and emperors to cure leprosy seems to date far back in history. Chinese history bears record of men who treated many lepers. Sun-Szu-Miao (A.D. 652) is reputed to have treated 600 cases. It is easy to understand how such a man might have had special clinics to see these people, who already in his day were considered outcasts, and who, therefore, most likely were not treated with other patients. In the province of Kiangsu, China, are found several specialists who treat only leprosy, and who have had their secret prescriptions transferred to them from father to son for several generations. These leprosy specialists, of whom the author knows several, give an extensive treatment of more than 3 months, making it necessary for the patient to come to the doctor over and over, thus developing leprosy clinics at their homes. All through the infested section of Kiangsu, the names and towns of these native leprosy specialists are known, and clinics automatically develop.

The spread of leprosy in Europe during the Middle Ages was undoubtedly due in part to the great movement known as the Crusades, and reacted a bit unfavorably toward the development of leprosy clinics as curative centers. Two extreme attitudes toward leprosy developed during the Middle Ages. On the one hand, fanatics in this already highly fanatic age, craved leprosy as a sign of holiness; while others, equally under the guise of religion, pronounced those suffering from leprosy as dead to society, and after preaching their funeral sermon sent them off to asylums for life. These asylums both in Europe and South America became centers for the treatment of lepers and all through history some medical men have given much thought to the treatment of this disease, developing certain clinics about them.

As a result of the Reformation when thinkers sought to give a reasonable account of their religious beliefs, and with the establishment of modern Christian missions, when men transformed their belief into acts, better days appeared for leprosy treatment. Attempts at the scientific mastery of this baffling disease went hand in hand with sympathetic care of those suffering from the disease. In this combined religious and scientific approach to the disease, hope for the patient suffering from leprosy arose, and large leprosy centers with clinics attached, came into existence in various lands.

A chain of such leprosaria and leprosy clinics now girdles the world and reaches out to every land where leprosy is found. In harmony with the present advanced public health consciousness, forced segregation is giving way to home and clinic treatment. The Orient has many leprosy clinics that make treatments possible

for thousands of patients who would not otherwise be able to receive care in leprosaria. The European countries in which leprosy is still found have likewise leprosy treatment centers. India and the Philippine Islands lead in clinic care.

Japan has not strongly developed the clinic idea for leprosy patients, and even in Taikoo, Korea, where there is one of the earliest and best developed leprosy clinics in the Far East, the Japanese Government now has suggested a retreat in this type of public health control.

LEPROSY CLINICS AND THEIR PURPOSE

Leprosy clinics in the ideal sense are public health centers used to control leprosy. This is done as well in treating the already affected individuals as in preventing the spread of the disease in the non-affected population.

The more we learn about leprosy the more difficult it becomes to draw a clear-cut line between the infected and the non-infective groups. It is now generally agreed that the earliest detected infectious cases have already harbored the infecting bacillus for several months before detected. To set a standard whereby to determine if cases are infected or not seems to be of prime importance. Some workers use the laboratory standard. If a case under repeated examination proves negative, the case is pronounced non-infective and hence not dangerous to society. Another group of workers determines its standard upon clinical observations; and a third group upon a combination of the two. The laboratory method is a purely objective one, and should be a safe guide in every positive case. Negative and doubtful cases, however, should be verified by clinical findings. The laboratory method, therefore, has its shortcomings in both early and late cases. When the disease is well marked clinically, the bacteriological findings are usually positive. The clinical method of determining the infective cases is subjective and hence has its limitations. All clinicians are not equally keen on detecting early leprosy. For the present we shall have to content ourselves with a standard that is based upon both clinical and laboratory findings. Even in the absence, however, of positive laboratory findings, a progressive numbness with anhidrosis, and beginning alopecia and discoloration of commonly affected parts in patients in a leper area should put a physician on his guard.

Once a standard is set for the determination of a case of leprosy, the government has a right, if it decrees that leprosy is a disease dangerous to the public health of the community, to compel positive cases of leprosy to submit themselves to treatment. This treatment must necessarily be free of charge to the patient and most human in all its methods. Segregation in institutions may be necessary in some cases, but must always be looked upon as the most extreme method any government can take in its public health control program.

The first method that suggests itself in modern public health control for leprosy infected areas is the organization of leprosy clinics where patients can go for diagnosis, get treatment, and be instructed in proper preventive measures to protect the non-affected population, and still remain at home. The number of such clinics will depend upon the extent of the leper area and the distances patients will have to go to the clinic. Large central clinics with laboratory facilities and small outlying clinics to bring the clinic to the patients, forming one complete unit, are usually found in large infected areas. The best examples of such clinics are found in India, in the Philippines and in the Dutch West and East Indies un-

der the new government program just recently put into effect.

Although this type of public health control of leprosy is still in its infancy, it promises to become the generally accepted method, as it aims primarily at general public health control along the most up-to-date theories of the prevention of other infectious diseases, is the cheapest method for the wholesale treatment of leprosy patients, and brings the greatest number of patients to the small number of fully qualified specialists that is available in the fight against this baffling disease.

LEPROSY CONTROL CLINICS

In practically every modern country of the world leprosy control is in hands of the national health department. Most countries have definite legislation for the control of leprosy. The various colonial possessions of the European nations have similar legislation. During periods of legislative control, leprosy has been greatly reduced in Europe, and consequently occurs rarely now in these countries. In no part of North America has leprosy ever developed to any alarming proportions.

In Africa and the Orient practically every country with the exception of China is now exercising a definite public health campaign against leprosy. Religious institutions have done their part in first calling attention to the need and giving the first help to the sufferers, but without government health legislation all this work had little value from a public health viewpoint.

The exceedingly progressive public health campaigns carried on by the British Government in India and Africa, the American Government in the Philippines, the Dutch and French Governments in their colonial possessions, have made leprosy control one of the major public health questions now discussed at the International Medical Conferences of the East.

A study of the leprosy control situation in China reveals that with the exception of South China, the government up to the present has not been able to take a firm hand. There is every reason to believe, however, that the National Health Administration of China, under the exceedingly able leadership of Dr. J. Heng Liu will before long set machinery into operation aiming at the control of leprosy in China, the most highly infected country of the world.

For the present most of the leprosy control work in China is in the hands of medical missionaries, largely financed by their home churches, and the British, American, and Chinese Mission to Lepers. Without government coöperation, it is evident, that the work done by these mission institutions is of very limited value from an active public health viewpoint. Religiously, philanthropically, and for propaganda purposes, the value of this pioneer work of medical missionaries cannot be overestimated. Much of this is an attempt to do real scientific work as well as religious and philanthropic, and is gratefully accepted by the government.

Leprosy clinics in China are of two kinds—one group is attached to the out-patient department of the general hospitals, the other is independent of the general hospital. Among the first, very few clinics develop to anything really worth while from a public health leprosy control viewpoint. These clinics are held largely with the purpose of keeping the unwanted leprosy patients away from the other out-patients. Sometimes certain days are set aside, in other cases after-clinic-hours are used for these special clinics. In our survey not less than 80 per cent of the leprosy clinics in China are of the latter type.

The second group of clinics, or those independent of the general hospital out-patient department, are either as-

sociated with leprosaria or are run entirely independently. The latter is more desirable as the clinics set themselves to a task quite different from that of most leprosaria. In our survey we find that clinics associated with leprosaria amount to 20 per cent of the whole, and the independent leper clinics make up less than 1 per cent of all leprosy combating agencies in China.

Of all the leper clinics in China we know of not one whose professional personnel devotes its time exclusively to leprosy.

As to the geographical distribution of the leprosy treatment centers, it is encouraging to note that in each of the 6 large leprosy areas of China some such clinics are found. The distribution is as follows:

LEPROSY TREATMENT CENTERS IN CHINA

Shantung Area	6%
Kiangsu Area (including Chekiang)	22%
Kansu Area	3%
Hunan-Kiangsi Area	15%
Kwantung-Fukien Area (largest area)	45%
Yunnan-Kweichow	9%
	100%

It would seem essential in case the National Health Department of China eventually passes legislation to include leprosy control within its scope, to incorporate all these clinics and institutions in its program.

Although the leprosy clinic in Shanghai, operated by the Chinese Mission to Lepers, can at its very best reach only a comparatively small number of patients, since the Shanghai area itself is not a leper area, but harbors several cases that come in from other parts of China, it may be said that this clinic can do very effective work in rounding up all the cases and treating them. The authorities of the various municipalities coöperate with the Mission to Lepers in leprosy control, and the various medical centers are being brought in line to coöperate with the Shanghai Leprosy Clinic in making this clinic accessible for teaching purposes. From various angles, therefore, this clinic becomes one of the most important clinics in China.

The leprosy clinic of Cheloo University Medical School is also largely used for teaching purposes and rates high as an active leprosy control agency in the oldest known leprosy area of China, the Shantung province.

The two largest leprosy clinics, both under mission auspices are one at Swatow under Dr. V. D. Fraser, and another at Jukao, Kiangsu, operated by the Christian Reformed Church of America. At each of these the number of patients attending the weekly clinic has reached 100 or more. Both clinics have laboratory facilities and give the latest in treatment. Both clinics are seeking to develop extension programs into the surrounding countryside.

China is one of the most heavily infected leprosy countries in the world and taking all these clinics together even when they are doing their very best work, it remains to be said of their attempt as of the five loaves and a few fishes to feed a multitude of five thousand, "What are these among so many?"

Administration of Health Education and Health Supervision in Negro Colleges

PAUL B. CORNELY, M.D., Dr.P.H.
Department of Bacteriology, Preventive Medicine and Public Health, School of Medicine, Howard University, Washington, D. C.

ACCORDING to the Committee on Approval of Negro schools,[1] the enrollment in Negro colleges has increased from 2,637 in 1916, to 26,339 in 1934–1935. Thus, approximately 27,000 persons aged 17 to 21 are in attendance at institutions of higher education for 2 to 4 or 5 years. It is said that less than 1 per cent of the population of the United States is composed of college graduates, and yet more than 50 per cent of the positions of influence and leadership in the life of the people are occupied by college men and women.[2] It may be assumed that if this group of future leaders is made health conscious through good health education and health supervision, they will in turn influence their families and communities and thus help in improving the health of the Negro. It is, therefore, of some importance to know the extent and status of health education in Negro colleges.

A questionnaire dealing with (1) the hygiene teaching, (2) the sanitary supervision, and (3) the health services offered to students during the school year 1933–1934 was sent to 99 Negro colleges. After repeated requests, 40 per cent of the schools responded. As shown in Table I, of the 40 schools, 38 reported an attendance of 11,909 students or about half of the total enrollment in Negro colleges.

TABLE I

ENROLLMENT IN NEGRO COLLEGES

Attendance	*No.*	*No. of 4 Yr. Colleges*	*No. of 2 Yr. Colleges*	*Total Attendance*
50– 99	4	1	3	271
100–299	20	16	4	4,157
300–499	6	6	..	2,283
500 and over	8	8	..	5,198
Attendance not given	2	0	2	....
Total	40	31	9	11,909

Of these 40 schools, 9 were 2 year colleges with an enrollment of approximately 800, since only 7 of these reported their attendance; and 31 were 4 year colleges with an enrollment of 11,131. For the purpose of discussion, the schools have been divided according to attendance. There are 4 with an attendance of less than 100 students; 20 of 100 to 299; 6 of 300 to 499, and 8 with 500 or more students. Thus, the majority of schools are to be found in the second group of 100 to 299 students.

Forsythe,[3] Hughes,[4] and Storey[5] have stated that health education should include 4 phases: (1) Informational Hygiene, (2) Administrative Hygiene, (3) Student Health Service, and (4) Applied Hygiene or Physical Education. In this study we have confined our interest to the status of the first 3 phases.

INFORMATIONAL HYGIENE

Hygiene teaching has become an integral part in the curricula of most colleges. Through lectures, library assignments, laboratory exercises and personal conferences, the student is able to understand the fundamental principles of human physiology, and is better able to comprehend the reasons for the health practices advocated. How is informational hygiene administered in this group of schools? Table II shows that of the 40 schools, 9 have a separate division of hygiene and health education; while in 31, the administration is placed in the hands of one or more departments.

TABLE II

INFORMATIONAL HYGIENE ADMINISTRATION

Attendance	*No.*	*Schools Having Separate Dept.*	*Schools Having Combined Dept.*
50– 99	4	..	4
100–299	20	3	17
300–499	6	3	3
500 and over	8	3	5
Attendance not given	2	..	2
Total	40	9	31

The departments in charge of hygiene teaching are shown in Table III.

TABLE III

Department Having Charge of Hygiene Teaching	*No. of Schools*
Physical Education	10
Natural Science	10
Home Economics	2
Social Science	1
Education	1
Academic	1
Two or more Departments	2
No data	4
Total	31

Thus, it is seen that approximately two-thirds of the schools have placed their educational activities in the department of physical education and natural science. The 9 schools which reported separate departments of health education stated that they had a total of 29 instructors engaged in hygiene teaching; while 28 of 31 schools with combined departments reported a total of 47 instructors. Of the 76 instructors, 47 had only college degrees; while 25 had done graduate work in some special field. These figures show an inadequacy in personnel both from the standpoint of quantity and quality.

Since the emphasis during the past 2 or 3 decades has been on health education, it would seem that one or more courses would be offered by every college. Table IV shows this not to be the case. Of the 40 schools, 34 stated that they offered courses in hygiene, but only 27, or 68 per cent, offered required hygiene courses. Thus, approximately 32 per cent of the schools leave their health education to the whims of the student. The 34 schools

TABLE V

SEX AND MENTAL HYGIENE

Courses	*Schools Responding*	*No. of Lectures Given*				*At Discretion of Teacher*
		None	*2*	*3*	*4–10*	
Sex Hygiene	28	8	7	2	8	3
Mental Hygiene	28	9	3	5	9	2

offered a total of 65 courses or an average of 1.9 courses per school; but approximately 50 per cent of this group offered only 1 course. The 27 schools which reported required courses gave a total of 44 courses, 19 of which were offered to freshmen; 2 to sophomores; 2 to seniors, 7 to physical education students; 12 to education and normal students; and 2 to home economics students.

In view of the importance of sex and mental hygiene in the curriculum, it is interesting to note from Table V that practically one-third of the schools do not include lectures on these subjects in their required courses.

The total attendance in these hygiene courses during the school year 1933–1934 is of interest. Of the 34 schools, 30 reported that 2,983 students attended the required and elective courses, 2,518, or 84.4 per cent, attended the required courses, and only 465 students the elective courses. These 30 schools had an approximate total attendance of 8,660 students. The small number in the elective course would seem to be due to lack of sufficient courses, or the inability of the initial hygiene course to stimulate desire for more knowledge of matters pertaining to individual and community health.

SANITATION

The tendency in public health work is primarily to stress individual health promotion, and sanitation has been somewhat pushed in the background. However, sanitation is an important item in college health activities and should always be considered. Of 40 schools, 35 stated that they carried out sanitary inspection. The administration of sanitation in Negro colleges is in the hands of various groups, as seen in Table VI. The work generally falls either on the matrons and deans or on the superintendents of buildings.

Twenty-seven of 35 schools show this to be true. The reports of 17 schools reveal that much of the function of these supervisors is concerned primarily with lighting, ventilation and water supplies in campus buildings. The dormitories in practically all instances

were inspected daily by the matrons or deans; but only 1 school out of 30 periodically inspected houses not on the campus. From the answers to the questions on sanitation, which were rather incomplete, one received the impression that houses not on the campus are considered approved as long as the proprietor is known to be respectable. Respectability seems to be more important than the knowledge of good sanitary practices. In no answer was the examination of food handlers, sanitation of kitchen, etc., mentioned.

As to the sanitary records, there is no unanimity as to where these should be kept. Only 13 of 35 schools kept sanitary records—6 in the business office or that of the superintendent of buildings and grounds; 2 in the president's office; 1 in the state department of health; 1 in the dean's office; 1 with head of the department of physical education; 1 in the division of hygiene and health, and 1 in the city health department.

STUDENT HEALTH SERVICES

The well conducted student health service is a very important factor in the college hygiene program because it serves as the avenue through which the individual is taught certain procedures which will be of importance to him in later life. The periodic health examination, dental examination, defense against quackery, good personal habits are factors which are generally instilled by association with a well organized health service. What is the status of health services in Negro colleges?

The administration of health services is in the hands of a variety of organizations as shown in Table VII. Only 70 per cent of the schools have this activity under the direction of a physician. The others are in the hands of a nurse, a dean, a matron, or in the physical education department. Of the 40 schools, 37 with a registration of approximately 11,000 students employed 117 physicians and nurses, not all on full-time basis. Table VIII shows that 11 schools employed 16 full-time physicians; 29 employed 46 part-time physicians, but most of these were in the capacity of consultants since only 5 schools had both part-time and full-time doctors; 18 had 32 full-time nurses; 12 had 13 part-time nurses, and 4 had 10 consulting specialists. What is more astounding is that 3 of the 40 schools employed neither physician nor nurse during the school year 1933–1934.

It would seem that an entrance physical examination would be a part of every health service, yet only 24 of the 40 schools require this, and in only 18 of these 24 was the examination exclusively performed by the school

* F.T. = Full-time; P.T. = Part-time.

physician. The figures for the different groups are shown in Table IX. Of the 16 schools which did not require entrance examination, 9 examined all their students during the first year; 2 examined them occasionally, and 5, or 13 per cent, offered no type of examination. Each of these 5 schools had an attendance of less than 300 students.

The results of the entrance physical examination are very short lived unless attempts are made to discover the effectiveness and the extent of corrections due to the entrance examination. Of the 24 schools which gave an entrance examination, 18 stated that they carried out certain follow-up procedures, 7 sent recommendations to parents, 7 performed reëxamination and again recommended corrections, while 4 sent their students to nearby clinics for corrections or offered treatment to them in their own clinic or dispensary. Thus, only 17 per cent of the schools made any effective effort to improve the status of the apparently healthy student. Figures on the percentage of corrections achieved during the first and second years in 3 of the 4 schools just mentioned are of some significance. Cheyney Teachers' College in Pennsylvania, which sends students to clinic in Philadelphia, stated that 25 per cent of the defects were corrected during the first year and 15 per cent during the second year of attendance. Tuskegee, which rechecks and offers treatment for defects during the semester, shows 25 per cent and 50 per cent corrections respectively; and Hampton Institute, where reëxamination followed by treatment is practised, stated that 75 per cent of the defects were corrected dur-

Total	40	39	34	5	20	13	1

ing the first year. Incidentally, Cheyney has less than 300 students, while the other two have more than 700 students each.

As to the health examinations of athletes, which is a definite responsibility of every college, it is seen in Table X that 34 of 39 schools answered this query in the affirmative. However, it is noticed that of these, 13 gave the responsibility to the coach rather than to a physician. Thus, it may be said that only about 50 per cent of the schools actually offer this service.

DISPENSARY SERVICE

The dispensary service plays a very important part in the prevention of disease in the college, since a centrally located and well organized dispensary beckons to the student when he first feels the symptoms of disease. Through friendly, sympathetic and scientific advice, diseases in the early stages are aborted, protracted treatments are avoided, and much loss of time from school and waste of money are prevented. Dispensary service is not found in all Negro colleges—33 per cent stated that they did not offer this service. This varied from 40 per cent in the group with an attendance of 100 to 299 students, to 17 per cent in the 300 or more group as shown in Table XI. Of the 27 schools which had dispensary service, 12, or a little less than half, were in charge of physicians; 10 in charge of nurses, and 4 were administered by matrons or deans.

The value of the dispensary is partly gauged by the number of calls made to it. In Table XII an attempt is made to analyze the problem in 10 colleges

Virginia State	639	No	No	R.N.	Fully Equip.	54.8

with an attendance of more than 300. It has been shown that the number of calls to college dispensaries varies with such factors as equipment, the requirement of a physical examination at entrance, the type of persons in charge, etc. This unfortunately cannot be shown in this table. It is noted, however, that the number of calls per 1,000 students per day, varies from 8.7 to 54.8, and that close to 40 per cent of the dispensaries fall below the standard of 30 calls.

The most common diseases treated in these dispensaries were reported by 18 of the 27 schools. Table XIII gives the diseases and the number of schools reporting them. The results are in agreement with more extensive morbidity studies in schools and in the general population carried out by the U. S. Public Health Service.[1, 2]

Attendance not given	2	2	2	..	..	1	1
Total	40	37	21	16	8	11	2

either through the hospital or the infirmary, or both, but is sadly lacking in Negro colleges. In Table XIV it is seen that only 21, or 57 per cent, of the schools provide this service. No school in the attendance group of less than 100 students had infirmary service, while in the group of 300 to 500 and over the percentage rose to 71. Even in the larger schools approximately 30 per cent have no bed care. As in the case of the dispensaries, the infirmaries are in charge of either a physician, nurse, or matron. As far as hospital care is concerned, only a small number have official hospital connection. Of the 40 schools, only 9 offered these services.

RECORDS AND FEES

Since the college student spends from 2 to 4 years in college, it is the responsibility of the college to keep a complete health record of every individual, so that each illness may be understood in the light of previous ailments, and every bit of advice, corrections, etc., may be recorded. In Table XV it is noted that only 21 of the 36 schools keep health records. Even in the 14 institutions with 300 or more students, only 10 keep such records, and they are kept in a variety of places—7 in a hospital or infirmary, 5 in the superintendent's or dean's office, 3 in the office of the school physician, 3 in the department of physical education, 2 in the office of a nurse, and 1 in the division of hygiene.

Total	40	36	21	15

Although the college is responsible for the health of the student, the latter should contribute financially to the upkeep of this service. In Table XVI it is noted that of 37 schools, only 24 required a health fee. Thus, approximately one-third of the schools make no charges. However, even in the schools which make this requirement, the amount collected is very small. Half of the schools have a fee of less than $4. Both of these factors may in a measure account for the paucity of health activities in this group of 40 schools.

SUMMARY AND CONCLUSIONS

The foregoing data reveal that in the 40 schools with half the total attendance found in all Negro colleges, the

health programs are very inadequate, and the impression is derived that most of these have been developed in a pell-mell fashion with no thought of coördination or completeness. Confusion in the administration and inadequacy of personnel, equipment and procedures are noticed in the hygiene teaching, sanitary supervision and health service. On the basis of this survey, these deficiencies would seem to be due to one or all of the following factors:

1. Very inadequate health fee
2. Lack of coördination of the reported practices and procedures
3. Lack of adequately trained personnel

Each of these factors can and should be ameliorated so that the bulk of Negro college students will receive a thorough training in the principles and practices of hygiene.

What Is the Air Hygiene Foundation?

THE Air Hygiene Foundation of America is an alliance of industry and science which seeks to eliminate or control industrial diseases caused by air pollution. Of special interest is silicosis, which endangers the health of workmen and investments of industry.

Leaders in steel, mining, glass, foundry, refractories, ceramics, the quarry, and kindred industries, realizing the need for coöperative action in facing the industrial dust problem, organized the Air Hygiene Foundation of America in 1935.

The Foundation is now engaged in a far-reaching undertaking, gathering together all pertinent facts relating to pneumoconiosis in the fields of medicine, engineering, and law.

This work is under the supervision of Managing Director H. B. Meller, and three major committees, the medical, engineering, and legal.

The Foundation is coöperating with the U. S. Department of Labor in its National Silicosis Conferences. The department in turn has promised coöperation to the Foundation in its activities. Coöperation has also been pledged by the U. S. Bureau of Mines, the U. S. Public Health Service, the American Standards Association, state medical societies, companies, corporations, and trade associations.

Effectiveness of the Methods of Dish and Utensil Washing in Public Eating and Drinking Establishments

ANDREW J. KROG AND DOROTHY S. DOUGHERTY

Health Officer, and Technician, Department of Health, Plainfield, N. J.

AWARE of the fact that many communicable infections are contracted orally and that public eating and drinking establishments are gaining in popularity, we decided to determine if utensils in these establishments might possibly be considered as vectors in the dissemination of infections which are spread from mouth to mouth. It seemed reasonable to believe that, if upon examination many organisms were found, the dishwashing process was unsatisfactory from a bactericidal standpoint because pathogenic as well as non-pathogenic bacteria would survive.

With this thought in mind we have endeavored to ascertain the bactericidal value of the methods of washing dishes, glasses, silverware, and other utensils in various public eating and drinking establishments. The survey as carried out by this department included restaurants, soda fountains, luncheonettes, and beer and liquor dispensing establishments. In the greater majority of these places, with the exception of those that dispense beer and liquors, the dishes and utensils are washed after each use in soapy water, the temperature of which is in most instances luke warm, followed by a hot or cold water rinse. Glasses used for dispensing beer and other alcoholic beverages are, in a few instances, washed in hot soapy water once daily and rinsed in cold water after each individual use. In the majority of alcoholic beverage dispensing shops, information was obtained which tends to show that the glasses are washed with soap and hot water at intervals varying from two to three times weekly. After each individual use they are rinsed only with cold water followed by polishing with a presumably clean towel.

SAMPLE COLLECTION KIT

The field equipment developed by this department to obtain bacteria counts from spoons, forks, tumblers, and dishes is as follows: Absorbent cotton swabs about ¾" x ¼" were made with 6" applicator sticks, and the upper end forced through a cork large enough barely to fit test tubes ⅞" in diameter by 5" in length. The stopper containing the swab was then placed lightly in the test tube and sterilized by autoclave, 15 lb. for 20 minutes. After sterilization the tubes are removed from the autoclave, and the stoppers are seated. These swab sets, several sterile 20 c.c. screw-cap vials, 10 c.c. sterile pipettes, a 212° F. thermometer, and several small bottles of sterile water constitute the kit used by the inspectors for obtaining the various samples for bacteriological examination.

SAMPLE COLLECTION TECHNIC

Samples were obtained by the following technic: During or just after the noon hour rush, from utensils which were washed and ready for the customers' use, a fork and a spoon were selected from the racks or drawers in which they were contained, and the entire area that comes in contact with the user's mouth was rubbed over at least three times with the sterile swab which had been just previously dampened in sterile distilled water. (It was found that if the swab was highly saturated with water, as it was passed over the surface of the utensil it would leave a film which might have a tendency to withdraw some of the organisms from the swab.) The swab was then immediately placed in the test tube. In the case of tumblers, two were selected and the same procedure was followed, but specimens were taken only from the area which ordinarily comes in contact with the lips, that is, approximately ½" down from the upper edge, and completely encircling the inner and outer surfaces. Samples (10 c.c.) of the wash and rinse waters were also taken by sterile pipette and placed in sterile screw-capped vials.

LABORATORY TECHNIC

The time lapse between the collection of the samples and their arrival at the laboratory for plating was from 1 to 3 hours. The procedure used in the laboratory for evaluating the number of bacteria was carried out as follows:

1. 5 c.c. of sterile water were added to each tube.
2. The swab handle was so adjusted in the stopper that the lower half of the swab was submerged.
3. The tube was then shaken violently against the palm of the hand 50 times for the purpose of liberating the bacteria from the swab.
4. Holding the swab handle between the thumb and index finger, the swab was then drawn up from the water and rolled against

the upper portion of the tube in order to expel therefrom as much of the remaining water as possible.

5. The swab was then removed and 1 c.c. of the water in the tube plated undiluted, and when desirable 1 c.c. of a 1 to 10 dilution was also planted.

The media used was Difco Nutrient Agar. Dilutions of 1 to 100 and 1 to 1,000 or higher when desirable, of rinse and wash water samples were also plated on similar media. In order to attempt to ascertain whether or not organisms of the coli-aerogenes group were present in a few instances, pour plates were made on Endo's media from a 1 to 100 dilution of the rinse and wash waters. An index of the laboratory results will be found in Tables I and II.

At the time of taking samples the inspectors recorded on previously prepared forms the general sanitary condition of the establishment, the method of washing and sterilizing the utensils, the physical appearance and temperatures of the wash and rinse water, the amount of visible debris on the utensils, the kind of soap, detergent, or sterilizing agent used, the method of drying, and whether or not automatic

washing machines were used. Temperatures of some of the wash and rinse waters will be found in Tables III and IV.

In none of the bars were glasses or mugs washed in either hot or cold soapy water after each use.

In view of the fact that the bacterial count was excessive in all wash and rinse waters and of many utensils, it seems conclusive that the methods used act only as a detergent by the partial removal of food particles from the various utensils, but do not have any appreciable bactericidal value. It seems only logical to conclude that the washing of silverware, glasses and dishes in water of a high bacteria content would cause their gross contamination which might possibly lead to the infection of many individuals when these waters are contaminated by utensils used by a person harboring disease producing organisms.

The proprietors of several restaurants and taverns have agreed to coöperate with this department in order that we may carry out control studies relative to various methods of chemical sterilization or disinfection of eating utensils. This work is now being carried out, and a report will be submitted at a later date.

National Medical Council on Birth Control

THE National Medical Council on Birth Control has recently been formed to control and supervise medical policies of the American Birth Control League and to initiate, encourage, and execute appropriate scientific research in the medical aspects of birth control.

Frederick C. Holden, M.D., of New York, is Chairman, and Eric M. Matsner, M.D., member A.P.H.A., of New York, is Executive Secretary of the Executive Committee.

Lead Content of Chewing Tobaccos and Snuffs

C. C. CASSIL AND C. M. SMITH
Division of Insecticide Investigations, Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, Washington, D. C.

IN 1921 Cadenhead and Jacques,[1] impressed by the fact that lead may find its way into smoking tobacco from the foil in which it may be wrapped, performed an experiment to show that, at least when lead was added to the tobacco to the extent of 17 per cent, small quantities might be volatilized during smoking and thus pass into the smoker's system. In 1929 Reitzel[2] summarized the work that had been done on poisoning resulting from lead in snuff. One other publication[3] on this subject has since appeared. No references to the occurrence of lead in chewing tobacco have been found.

In all the publications mentioned the presence of the lead was attributed to the use of lead chromate to improve the color of snuff, or to contamination from the lead containing foils in which the products were wrapped. The lead content is stated to have been over 3 per cent in one case.

It is probable that cases of such gross contamination are rare today, but since lead arsenate is used in protecting growing tobacco from damage by insects, it is evident that many manufactured tobacco products will contain at least traces of lead.* Reitzel[2] refers to this possible source of contamination. The literature appears to contain no recent references to any extended analyses for lead of various brands of tobacco products, probably for the reason suggested by Reitzel, namely, that the Food and Drugs Act does not include tobacco products within its scope. The suspected snuffs in the cases reported by Bauer and Ropes[4] contained about 0.2 grain of lead per pound (30 p.p.m.), which may have been due to spray residue.

Because of the chance of direct entry of lead into the system from the use of chewing tobacco and snuff, an investigation of its occurrence in these two products was undertaken. Seven samples of snuff and 9 of chewing tobacco, representing in each group the products of 6 manufacturers, were obtained from stores in Washington, D. C. The samples of chewing tobacco were first dried so that they could be ground in a mortar. Both the weights as received and the dry weights were recorded so that the results could be calculated back to the original basis. After pulverization and thorough mixing, duplicate samples were taken for analysis.

The snuffs were all in such a form that no grinding was necessary. Two or more boxes of snuff were well mixed together before samples were taken.

Chewing tobacco No. 5 was taken from a package having an outside wrapping of metallic foil that was found to contain a large percentage of lead.

* The present policy of the Department of Agriculture is to discourage the use of lead arsenate for the control of leaf-feeding tobacco pests in cases where large deposits of the material will be left on the crop at harvest time.

There was, however, a sheet of waxed paper next to the tobacco, and it is unlikely that the metal wrapper contributed much to the lead content. The metallic labels on some of the plug tobaccos were found to be free of lead.

Considerable difficulty was encountered in developing a method for the determination of lead. Of several tried, the electrolytic " mush " method as used for the determination of lead in sprayed apples [5] appeared most promising, but the results obtained at first were not consistent because of the formation of a precipitate when the solution containing the lead was made alkaline preparatory to the extraction of the lead with a chloroform solution of diphenylthiocarbazone. It is believed that this precipitate, probably consisting largely of the phosphates of the calcium and iron groups, occludes some of the lead. It was discovered, however, that sodium hexametaphosphate * will prevent the formation of this precipitate, or at least retard it sufficiently to permit the extraction to be made. Even so, 10 grams of tobacco was the most that could be handled, and this forced the adoption of the small anode and the very dilute thiosulphate solution used in the later stages of the procedure. The method as finally adopted is described in some detail here, because careful observance of these details is necessary if satisfactory results are to be obtained.

ANALYTICAL PROCEDURE FOR LEAD

Place 10 gm. of tobacco (dry weight) in a 400 c.c. beaker, moisten with water (to prevent combustion when heated with nitric acid), and add 50 c.c. of concentrated nitric acid. Allow the contents to stand, with a watch glass over the beaker, until the initial action has subsided. Place the beaker over a flame and boil for about ½ hour or until the material is well mushed. Dilute the mushed solution when cool, transfer to a 300 c.c. volumetric flask, make to the mark, allow to stand for 15 minutes (shaking at short intervals), filter, and take a suitable aliquot (200 c.c.) for the analysis. Add to the aliquot in a 500 c.c. separatory funnel, 20 c.c. of citric acid (20 per cent w/v) and 8 gm. of sodium hexametaphosphate, make this solution just alkaline with ammonium hydroxide, and add 10 c.c. of potassium cyanide solution (10 per cent w/v). Extract with small portions of dithizone (diphenylthiocarbazone) solution in chloroform (0.05 per cent w/v) until the color of one portion remains unchanged. Drain the successive chloroform extracts into a smaller separatory funnel containing 20 c.c. of ammonium hydroxide (1 + 99), and shake as a means of washing the chloroform. When the extraction is complete, drain the combined portions of dithizone-chloroform solution (containing the lead) into a 150 c.c. beaker and evaporate to dryness over a steam bath. After the chloroform has been completely evaporated, add 2 c.c. of concentrated nitric acid, place a watch glass over the beaker, and boil until the gases evolved are colorless. Dilute to about 100 c.c., heat to 75° to 85° C., add 2 c.c. of a saturated solution of potassium dichromate, and electrolyze (maintaining the stated temperature) with 80—90 milliamperes for 20 minutes, using a small 1" by 5/16" rotating cylindrical platinum-gauze electrode. Dissolve the lead peroxide in a mixture of 2 c.c. of potassium iodide (2 per cent w/v) and 4 c.c. of acid sodium acetate solution (20 c.c. of saturated solution sodium acetate, 10 c.c. of glacial acetic acid, and 70 c.c. of water). Titrate with approximately

* This compound is available commercially as a detergent, manufactured by Calgon, Inc., Pittsburgh, Pa.

0.001 N sodium thiosulphate* that has previously been standardized against a known amount of lead.

Since no considerable quantity of tobacco that was known to be free from lead arsenate spray residue could be obtained, it was necessary to judge the results from this method by the difference between two otherwise identical samples, to one of which a known amount of lead had been added. Recoveries of only 90 per cent were obtained, and repeated efforts to improve this recovery failed. In an attempt to trace the source of loss of the 10 per cent of lead in the samples, the lead was added after filtration, when all the silica had been filtered off, instead of before mushing. When the lead was added at this stage, the analyses showed a 99 per cent recovery. This places the cause of the loss on some of the insoluble material, which contains for the most part silica and organic matter. Silica has given trouble in other methods that have been tried and is thought to be responsible here. As the time that could be devoted to the study was limited, the results are offered subject to this limitation. Although arsenic was not of primary interest here, it was determined in all samples to confirm the belief that the lead originated in the insecticidal lead arsenate used on the tobacco. The method used was that developed by C. R. Gross.[6] The results for both lead and arsenic are given in Table I.

TABLE I

LEAD AND ARSENIC IN CHEWING TOBACCO AND SNUFF

Sample	Pb* Gr./lb.	As_2O_3* Gr./lb.	Ratio Pb/As_2O_3

15	0.500	0.224	2.2:1
16	0.194	0.116	1.7:1
17	0.711	0.303	2.3:1
18	0.853	0.315	2.7:1

* Calculated on basis of samples as received

If lead arsenate were the only source of contamination, the ratio Pb/As_2O_3 should be 2.1: 1. Many of the observed ratios approximate this value, and those that are lower might be due to the use of other arsenical insecticides in addition to lead arsenate.

The maximum figures for lead in chewing tobacco and snuff are equivalent to 85 and 131 p.p.m., respectively, both in excess of the 30 p.p.m. found by Bauer and Ropes in samples of snuff suspected by them of causing lead poisoning.

SUMMARY

A method for the determination of lead in tobacco has been worked out which yields a recovery of about 90 per cent. This procedure has been applied to 7 samples of snuff and 9 of chewing tobaccos. The amount of lead present ranged from 0.025 to 0.610 gr. per lb. (3.5 to 85 p.p.m.) in the chewing tobaccos and from 0.088 to 0.935 gr. per lb. (12 to 131 p.p.m.) in the snuffs. The arsenic trioxide content of the chewing tobaccos ranged from 0.029 to 0.261 gr. per lb. (4.1 to 36 p.p.m.) and of the snuffs from 0.035 to 0.364 gr. per lb. (4.9 to 51 p.p.m.).

* This very dilute thio may be protected from decomposition for several weeks by adding 1 per cent of amyl alcohol to the boiled water with which it is prepared.

From the Pb/As_2O_3 ratios found, it is probable that the presence of lead is due to dusting of the tobacco in the field with lead arsenate.

Resolution Adopted by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, June, 1936

WHEREAS, at the annual meeting of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association held at St. Louis, Mo., February 25, 1936, a presentation was made by Joel I. Connolly, of the Chicago Board of Health, relating to possible health hazards in apparently modern plumbing installations in public buildings, and

WHEREAS, it was manifest in the said presentation that plumbing fixtures which have been generally regarded as safe and sanitary in design may in fact constitute a real and serious health hazard by reason of the danger of back siphonage and contamination of water supply mains, and

WHEREAS, the probability exists that such apparently modern, safe, and sanitary plumbing installations may exist in numerous school building in the United States, and

WHEREAS, the existence of such apparently safe, modern and sanitary plumbing installations and reliance upon them brings about a sense of false security, therefore, be it

RESOLVED, by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association that this Committee apprehends the possibility of danger to the health of school children from apparently safe, modern, and sanitary plumbing installations in school buildings, and be it further

RESOLVED, that the said Joint Committee earnestly recommends to all school boards and school executives that surveys be instituted by competent engineers to ascertain whether or not the danger of back siphonage and consequent pollution of water supply mains exist in plumbing installations within their jurisdictions, and that such surveys be followed by prompt corrective measures, and be it further

RESOLVED, that these resolutions be offered for publication to all journals dealing with public health, health education and general education.

Factors Influencing the Vitamin C Content of Vegetables*†

DONALD K. TRESSLER, PH.D., AND GUILFORD L. MACK
New York State Agricultural Experiment Station, Geneva, N. Y.
AND C. G. KING, PH.D.
Chemistry Department, University of Pittsburgh, Pittsburgh, Pa.

FRESH raw vegetables have long been known to possess antiscorbutic properties. In 1747 James Lind, a surgeon of the British Navy, indicated that scurvy could be cured by the eating of green vegetables. In 1912 Holst and Frölich demonstrated that experimental scurvy in guinea pigs could be cured by the addition of small amounts of cabbage, turnips, or dandelion to the vitamin C deficient diet. There is little agreement, however, concerning the amount of vitamin C contained in a given vegetable. In a recent survey of the literature relating to the vitamin C content of spinach,[1] we have found that the amount of ascorbic acid reported by various workers ranged from 0.07 to 0.62 mg. per gm. of spinach. These calculations are based upon the assumption that 0.5 mg. of ascorbic acid per day is required for protection of a guinea pig from scurvy (Bessey and King[2]). Similar variations in the reported ascorbic acid content of most other vegetables may be noted.

While variations in technic employed in making the vitamin C estimations may account for some of the differences in the results obtained, it is probable that each of the common vegetables does vary widely in ascorbic acid content.

Variety,[1, 2, 3] freshness,[1, 2, 4, 5] and maturity [1, 2, 4] have already been indicated as factors affecting the vitamin C content of vegetables. However, no one has carried out sufficiently detailed studies of the ascorbic acid content of the different vegetables to show the relative influence of these and other factors.

Von Hahn and Görbing [6] and others have suggested that the nature of the fertilizer has an influence on the ascorbic acid content of the vegetable produced.

There is little agreement among workers as to the effect of open kettle cooking on the vitamin C potency of vegetables. Similarly, the extent of loss of this vitamin during preparation for freezing has not been definitely defined, although Fellers [7] has conducted preliminary experiments along this line.

Because of the lack of exact knowledge on the points mentioned above, a detailed study of these and other factors affecting the ascorbic acid content of vegetables has been begun in our laboratories. Thus far, the vitamin

(on upland soil)	12	0.89	0.53	0.73
Fall Spinach (on muck soil)	12	0.67	0.48	0.60
(on upland soil)	11	1.13	0.72	0.99

C content of spinach, rhubarb, peas, snap beans, cabbage, and tomatoes has been considered.

METHODS USED

The method of determining ascorbic acid described by Bessey and King[2] was employed in the examination of spinach, rhubarb, and peas. In determining the ascorbic acid content of snap beans and cabbage, the acetic acid solution used for extraction according to the above procedure was replaced by a mixture of acids, 1 N with respect to sulphuric and N/4 with respect to metaphosphoric. This solution has been found to give a more complete extraction of the ascorbic acid, and, moreover, the metaphosphoric acid prevents loss by catalytic oxidation. The details of the procedure employed are being published in another paper.

Representative samples of spinach, peas, snap beans, and cabbage, analyzed by the indophenol titration method have been checked by bioassays according to the procedure described by Tressler, Mack, and King.[1] In general, the results obtained by the two methods agree closely.

VARIETY STUDIES

A general resumé of our variety studies is presented in Table I. From these data it is seen that variety is a factor of considerable importance in the case of peas, snap beans, tomatoes, cabbage, and spinach. However, there was little difference in the ascorbic acid content of the two varieties of rhubarb examined.

In general, small-seeded peas, such as the Alaska variety, were found to have approximately one-half more ascorbic acid than the large seeded varieties.

The Georgian and Blue Lake varieties of snap beans contain only approximately one-half the amount of vitamin C found in the Tendergreen, Kidney Wax, Ideal Market, and Kentucky Wonder varieties.

The Golden Queen and Early Detroit tomatoes had a much higher ascorbic acid content than the other varieties examined.

The Princess Juliana and King of Denmark varieties of spinach were found to be lower in ascorbic acid than the other ten varieties grown in the spring, containing only about three-fourths as much as the Eskimo, Old Dominion, and Nobel varieties. This same relation did not hold in the case of the autumn spinach grown on muck soil.

TABLE II

ASCORBIC ACID CONTENT OF THE LEAVES OF SEVERAL VARIETIES OF SPINACH GROWN IN SPRING AND AUTUMN ON DIFFERENT SOIL TYPES

	Ascorbic Acid in Mg. per Gm. of Spinach Grown in			
	Spring		*Autumn*

INFLUENCE OF GROWING CONDITIONS

This preliminary study of the vitamin C content of spring and autumn spinach grown on upland and muck soils has convinced us that, at least in the case of leafy vegetables, the soil on which they are grown, and growing conditions have a decided influence on the ascorbic acid content. The average amount of ascorbic acid in spinach leaves grown in the spring on upland soil was 50 per cent higher than that of the spinach from muck soil (Table II). The same statement is true for autumn spinach, but while the spring upland spinach averaged only about 0.73 mg. ascorbic acid per gm., the autumn upland spinach averaged 0.96 mg. per gm. Similarly, the spring muck spinach averaged 0.49 mg. ascorbic acid per gm. and the autumn muck spinach 0.60 mg. per gm. In other words, it appears that autumn spinach contains nearly a third more vitamin C than spring spinach. These conclusions are based upon the results of a single season's work. They will have to be verified in other years in order to be more certain of the validity of these findings.

MATURITY AS A FACTOR

Fully ripe tomatoes were found to be nearly twice as high in ascorbic acid as green tomatoes.

As green peas mature, the percen-

"	23 to 26	0.79	0.39	0.03	Spoiled

tage of ascorbic acid decreases, probably because of the rapidly increasing dry matter content and lowered respiration.

In the case of spinach, snap beans, and rhubarb, the percentage of ascorbic acid was approximately the same at all of the stages of maturity at which these vegetables were examined.

LOSS OF VITAMIN C DURING STORAGE

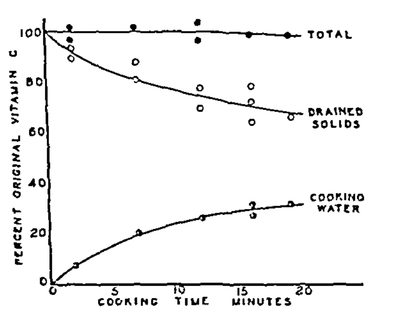
Freshly harvested spinach on standing for 3 days at room temperature lost approximately one-half of its ascorbic acid (Table III). But after 3 days' storage at 1 to 3° C., the spinach was found to retain practically all of its vitamin C. A similar result was obtained with snap beans and green peas.

On the other hand, the more acidic vegetables, rhubarb and tomatoes, lost very little ascorbic acid even when held at room temperature for a week.

EFFECT OF COOKING

Preliminary cooking studies conducted on peas, snap beans, and cabbage indicate that a considerable proportion of the ascorbic acid passes into the water during the boiling of vegetables, but the total amount of ascorbic acid decreases but little. In the case of boiling of snap beans (Figure I), approximately one-third of the vitamin C dissolved in the cooking water in 20 minutes' time, but the actual destruction of this vitamin was on the average less than 10 per cent of the total present.

FIGURE I



THE EFFECT OF COOKING ON THE VITAMIN C CONTENT OF STRING BEANS

PREPARATION OF VEGETABLES FOR FREEZING

Preliminary studies on the losses of vitamin C during preparation for freezing, freezing, cold storage, and thawing of peas have shown that blanching, sufficient to inactivate catalase, is necessary in preparing vegetables for freezing in order to eliminate loss of ascorbic acid during storage of the frozen vegetables at the temperatures commonly employed commercially (—18 to —9° C.).

During blanching of peas there is some loss of ascorbic acid. This varies from 10 to 30 per cent depending upon the type and severity of the blanching treatment. Water blanching causes a slightly greater loss of ascorbic acid than steam blanching, probably because some of it is dissolved by the blanching water.

Thawed vegetables gradually lose their vitamin C. This indicates the value of cooking without preliminary defrosting.

PUBLIC HEALTH SIGNIFICANCE OF THESE FINDINGS

The fact that certain varieties of tomatoes contain 50 per cent more vitamin C than others indicates clearly that packers of this juice should give more attention to the varieties grown. Canners of spinach attempting to obtain a canned product of high vitamin C potency should consider not only the variety, but also the season, and the soil on which their raw material is grown.

Since certain vegetables lose half their vitamin C content when held at room temperatures for 3 days, and since the rate of loss is much lower when

they are refrigerated, the necessity of prompt cooling of all except the more acidic vegetables, such as tomatoes and rhubarb, is obvious if their full nutritive values are to be retained. These studies should be continued in order to determine the optimum conditions of storage of all vegetables necessary to obtain the maximum retention of nutrients.

Of still greater significance, from the standpoint of public health, are the observations that, contrary to the general belief, but little vitamin C is destroyed during cooking. It is probable that this idea became prevalent because but few nutritional investigators took into consideration the amount of this vitamin which dissolved in the cooking water. The fact that the water in which vegetables, rich in vitamin C, have been cooked may be as rich in this vitamin as tomato juice is of great importance. It is evident that methods of cookery should be adopted which will make use of this nutritionally valuable substance which is too often discarded.

SUMMARY AND CONCLUSIONS

Variety is a factor of considerable importance in determining the ascorbic acid content of peas, snap beans, tomatoes, cabbage, and spinach.

Soil and growing conditions affect the vitamin C content of spinach.

The ascorbic acid content of tomatoes increases as they ripen. On the other hand, the percentage of vitamin C in peas decreases as they mature.

Snap beans, peas, and spinach rapidly lose ascorbic acid if held at room temperature. Refrigeration greatly reduces the rate of loss.

Preliminary cooking studies indicate that a considerable proportion of the ascorbic acid passes into the water during cooking by boiling, but the total amount decreases relatively little.

Blanching is necessary in preparing vegetables for freezing, in order to retain the ascorbic acid content of the frozen vegetables at the usual cold storage temperatures. Thawed vegetables slowly lose vitamin C.

Use of Nigrosine to Demonstrate Treponema Pallidum in Syphilitic Lesions

ROBERT B. DIENST, PH.D., AND
EVERETT S. SANDERSON, PH.D., M.D.
Department of Bacteriology and Public Health, University of Georgia, School of Medicine, Augusta, Ga.

AS spirochetes are notoriously difficult to stain, the characteristic morphology of *Treponema pallidum* can best be demonstrated by darkfield illumination or by methods which stain the background, leaving the organisms colorless. Many agents have been used for the purpose of staining the background, such as India ink, collargol and Congo-red. We find that nigrosine * is far superior to any agent used for this particular purpose as it is highly colloidal and when the smear is properly prepared the spirochetes may be easily detected and are characteristically pictured.

The detection of the spirochetes (*T. pallida*) is of diagnostic value in the recognition of doubtful cases of syphilis and is a factor of considerable importance in the relation to early diagnosis. Successful results depend upon the selection of the most suitable material for examination and the most suitable method of collection. We suggest that the primary ulcer and papules be thoroughly cleansed with soap and water and the surface rubbed dry with a sterile pad. The ulcer should then be squeezed so that a clear exudate is extruded from the lower layers of the induration. For the examination of glandular fluid it is advisable to puncture the enlarged gland by means of a sterile syringe and obtain sufficient quantity of tissue fluid from the glands by aspiration, perhaps assisted by light massage. According to the investigations of Hoffman and Lipschutz,[1] the peripheral portions of the glands contain the spirochetes in greater numbers than the central portions.

METHOD FOR STAINING

Wet Preparation—A small loopful of the exudate is placed on a clean slide and to this is added a loopful of a 5 per cent aqueous solution of nigrosine to which ½ per cent formalin has been added as a preservative. The material is thoroughly mixed and spread over the slide until the proper thinness is obtained. In mixing the material one usually gets satisfactory thinness by starting in the center of the drop and by rotary movements gradually increase the size of the smear by spreading out from the center. In this way some portion of the smear will be ideal for

* Nigrosine (synonyms: nigrosin W. Gray R, B, BB. Silver gray. Steel gray. Indulin black) is not a pure dye, but is a mixture, and apparently the composition of different lots may vary. Ordinarily it is a mixture of a blue-black or violet indulin with a yellow dye in such a proportion that the resulting blend appears black. Our dye was obtained from Coleman and Bell.

P—Positive; N—Negative; O—No test made

* In this particular slide spirochetes were seen but their morphology was not typical of *Treponema pallidum*.

examination. When the proper thinness is obtained the slide is passed over the flame to dry the preparation rapidly. A drop of oil is placed directly on the dried smear and examined under the oil immersion objective. A good substage lamp should be used so that the field is properly illuminated. If the slide is to be used for future reference, the oil is best removed by immersing it in a coplin jar of xylol for a few minutes. One should not blot the excess oil because any rubbing will cause scratches on the preparation.*

Dry Smear—A drop of the exudate may be left to air-dry on the slide. At some later date place a small loopful of water on the dried area, allow to remain a few seconds to dissolve the exudate, and then place a loopful of nigrosine, smear, and dry. In this manner we have obtained excellent results from preparations sent to us from different laboratories. In several cases the exudate had been dried on the slide

* We would suggest to anyone using this method of demonstrating the presence of spirochetes to try staining the spirochetes from the mouth so that one may learn the proper thinness of the smear to detect more easily the presence of spirochetes.

45 days before we applied the nigrosine stain. This method of sending dried smears into the laboratory would be much simpler and probably more satisfactory than the present method of rushing a saline exudate in a sealed tube to the laboratory for diagnosis under the darkfield illumination. The sooner, however, the smear is redissolved and stained, the better the *Treponema pallida* stand out against the dark background.

RESULTS

1. This method of demonstrating the presence of *Treponema pallidum* in primary ulcers and papules has been successful in all but 1 case in which either the darkfield examination or the serology was positive for syphilis. In 1 case the nigrosine preparation was positive and the darkfield negative. The serum from this patient later gave a positive Wassermann reaction.

2. This method would simplify the present one used in most state laboratories for the diagnosis of syphilis as the dried exudate could be sent to the laboratory on a slide and a satisfactory diagnosis made from this. In 12 out of 13 smears our findings checked with the darkfield examinations made in other laboratories. Some of these smears were 45 days old before being stained with the nigrosine.

3. This method is much simpler and apparently as accurate as the darkfield examination.

Epidemiological Features of a Typhoid Fever Outbreak in West Philadelphia Following a Supper

GEORGE E. JOHNSON, M.D.

Chief and Head Diagnostician, Division of Communicable Diseases, Department of Public Health, Philadelphia, Pa.

THE great reduction in typhoid fever which has taken place during the past few decades represents an achievement in preventive medicine of which sanitarians and health officials alike are proud. Philadelphia has been congratulating herself upon the steadily declining case and death rates of this disease, which in 1933 reached a minimum of 105 cases, and a death rate of 0.6 per 100,000, thereby winning second honor among the metropolitan cities of the country. Contrast these figures with those for 1906 when 9,712 cases and 1,063 deaths were reported. However, this occurred before the days of filtration and chlorination in 1913, when Philadelphia was widely known as a typhoid city.

As a further safeguard against the dissemination of this disease, the Board of Health in 1914 promulgated compulsory pasteurization of the city milk supply. Prior to pasteurization many of our local outbreaks were traced to milk infected by patients or carriers, including 46 cases in 1906, 25 in 1908, and 149 in 1912.

After the elimination of water and milk as major sources of infection, attention became centered on the prevention, detection, and control of chronic carriers, who in 1922 were placed under the jurisdiction of the Department of Public Health. In this same year a striking example of a carrier infection occurred in the home of a physician when 3 of his family were infected by the cook. This same carrier before recognition, had conducted an oyster saloon in South Philadelphia, and, in working back, is regarded as the probable source of infection in a number of obscure local outbreaks in this locality.

It would seem that, with the safeguarding of our water and food supplies, sanitary disposal of sewage, control of known cases and carriers, the further reduction in typhoid fever should be effected through epidemiological investigations of sporadic cases or epidemics, to discover carriers and prevent them from spreading the disease.

This recent outbreak is a reminder that the gains apparently made in the control of typhoid fever are still insecurely held and that only by contant vigilance and tireless investigation can the safeguards promulgated be applied and enforced.

HISTORY

A Memorial Day supper given by a Legion Post was attended by 264 patrons and guests: 228 of whom were Philadelphians, 110 males, 118 females

—76 adults and 152 children. There were approximately 36 persons living in townships adjacent to Philadelphia who attended the supper.

The epidemic began with 2 cases of typhoid fever, mother and child, living in West Philadelphia, reported June 18, 1935, from a hospital. Following the routine investigation by our medical inspector it was learned that the mother and child had visited various places including the Post supper, and that the mother had been drinking spring water at her place of employment.

On June 20, 2 children living in the neighborhood of the first patients were taken to a Delaware County hospital, with suspected typhoid—diagnosis confirmed later. The following day 3 other children in the same neighborhood were reported as having typhoid by the attending physician. All the patients gave a common history of having attended the supper at the Post.

By elimination of other sources of infection the supper seemed potentially the most incriminated, and an investigation of all food and drink served, as well as of all persons who prepared and handled it, was immediately undertaken. The sanitation, plumbing, and water supply were checked by the Division of Sanitation. Coincidently, all physicians and hospitals in the region involved, were notified by telephone to be on the lookout for suspected cases of typhoid fever, and warned of the possibility of an epidemic.

On June 21, a list of all who attended the supper was obtained from the officers of the Legion, and divided among 5 inspectors who immediately started to visit all of the homes involved, inquired regarding any past or present illness, the type of food eaten, whether any one handled or prepared food or drink served, whether accompanied by guests, and urged typhoid immunization by the family physician or Department of Public Health.

All those who supplied or handled food or drink at the supper were sent to the Laboratory of Hygiene to submit blood for Widals, and urine and feces for bacteriological examination. On June 23, 7 were sent to the laboratory, and thereafter 7 daily until all, numbering 44—20 food servers and 24 employed in 8 stores supplying food—had reported. Many found negative were required to submit 2 additional consecutive negative specimens.

The following foods were served: home-made potato-salad, cold boiled ham, olives, pickles, boiled eggs, butter, tomatoes, lettuce, home-made cakes, cheese, ice cream, bread and rolls; with beer, soda water, coffee, cream for coffee, and city tap water. Each article of food was investigated individually.

The bulk of the food was supplied by one grocer, who, with 3 employees, was among the first to submit specimens at the laboratory. The potato-salad, which from the first was under suspicion, was made by these 4 persons.

June 23 and 24, 13 additional cases, with histories of having attended the supper and of having partaken of the potato-salad, were reported to the department.

The Post supper was served with 150 lb. of potato-salad, and a few pounds of the same batch were sold over the counter to customers. Only 1 family, mother and daughter, could be located, who, on May 30, purchased some potato-salad and were subsequently taken ill with typhoid fever and hospitalized. They did not attend the supper.

On June 22, it was learned that a portion of potato-salad left over from the supper had been stored in the icebox of the Legion Post House, and on May 31, was given to a man, the father of 6 children none of whom had attended the supper. The father, mother, and 1 child ate the salad. The mother and child came down with typhoid, the

father escaping. Attention was focused on the potato-salad as the source of infection, since all patients, including children, gave histories of having eaten it.

On June 25, the laboratory reported as positive the urine and feces of a woman who was one of the 4 who prepared the potato-salad. This person was removed to the Philadelphia Hospital for Contagious Diseases, and 2 additional successive positive cultures on feces, and 2 on successive biliary drainages were reported by the Laboratory of Hygiene.

On June 28, a positive fecal culture was obtained on a second woman who assisted in serving food at the supper. She too was removed to the hospital, and 2 additional positives on feces and bile were obtained. Both gave positive Widal reactions, Carrier No. 1, 1–60 dilution, and Carrier No. 2, 1–300.

Following a careful investigation of the duties at the supper of Carrier No. 2, which consisted in passing trays without directly handling food, this department felt that she could be definitely eliminated as the source of infection, and was convinced that Carrier No. 1 was the true source.

A brief social and medical history of this carrier follows:

Carrier No. 1—She is white, born in Germany, 58 years old, weighing 185 lb., and has lived at the grocery noted, for the past 25 years. There is a history of illness 8 years ago when she was confined to bed for a period of 2 to 3 weeks, with fever and occasional delirium. The attending physician recalls treating this patient, but has a hazy recollection as to the nature of her illness. She claims to have previously prepared potato-salad in the same German way, and rarely prepared other foods, but usually waited on customers at the grocery. Apparently she is an intermittent type of chronic carrier, but in the preparation of this particular lot of potato-salad evidently introduced a virulent organism in massive dosage.

Our typhoid incidence in the city ward in which the grocery is located, shows that only 10 of 23 cases reported from 1928 to onset of recent outbreak could not be definitely traced. Whether or not she was responsible for any of the 10 cannot be determined.

After her discharge from the Philadelphia Hospital for Contagious Diseases she was admitted to one of our Philadelphia hospitals where she was studied preliminary to a contemplated cholecystectomy for the carrier condition. The laboratory findings paralleled those previously found. Cultures taken of material under nail of third finger, left hand, and from skin folds about anus and cleft of buttocks, were positive. On July 18, a cholecystectomy was performed, and bile ducts injected with 1 per cent pyoktanin. One large gall stone was found in gall-bladder, the mucosa of which was thickened and inflamed showing fibroid changes, and was positive for *B. typhosus*. The free bile and inspissated bile covering calculus gave pure cultures. Five days after operation, cultures of urine and feces were negative. Patient was discharged August 13, and since has had 3 positive and 1 negative cultures from fecal specimens. She is not living at the grocery, and is under observation of the Department of Public Health conforming to rules and regulations governing chronic typhoid carriers.

The greatest number of cases reported in a single day was 25 on June 27, and the last was reported on July 31, totaling 86 cases with 6 deaths, a case death rate of 7 per cent (see Table I).

Every effort was made to hospitalize cases, and immunize contacts. There were 31 cases admitted to the Philadelphia Hospital for Contagious Diseases, 35 at the Philadelphia General Hospital, 17 at other Philadelphia hospitals, and 3 remained at home, a total of 83 or 96.5 per cent hospitalized. There were 2 instances in which 5 cases occurred in one house; 6 primary and 4 secondary. There were 242 persons immunized at the Post headquarters by 7 medical inspectors who functioned one evening each week for 4 consecutive weeks. This number does not include those immunized by the attending physicians of whom we have no accurate record. There were 145 homes visited by our inspectors,

TABLE I

WEST PHILADELPHIA EPIDEMIC—TYPHOID FEVER, 1935

86 CASES—6 DEATHS

Cases—Age Groups

	1–5 Years	6–10 Years	11–15 Years	16–20 Years	21–30 Years	31–40 Years	41–50 Years	Over 50 Years	Total	Sex Percentage

	0	0	3	1	0	1	1	0	6	

and approximately 5,000 visits made by them. Every house was visited daily for 10 days, then every other day for 6 days, and 2 final visits thereafter, making 15 visits to every house over a period of 3 weeks. There were 9 secondary cases.

The addresses of known out of town contacts and patrons attending the supper were forwarded to respective health officers for investigation and observation. We have no accurate record of how many such cases developed typhoid, but know of at least 6.

SUMMARY

1. Description of a serious outbreak of typhoid fever among patrons and guests attending a supper given in honor of an American Legion Post.

2. The promptness of discovery of a chronic typhoid carrier in the rôle of a food handler who contaminated potato-salad which caused the outbreak, and the discovery of the source of the epidemic within 5 days after the first case was reported to the Department of Public Health.

3. The efficiency and promptness with which cases were discovered and hospitalized, and contacts safeguarded and immunized.

4. The earnest coöperation received from physicians, hospitals, Post officials, and the laity in the control and abatement of this epidemic.

5. The present-day status of the chronic typhoid carrier in the incidence of typhoid fever, and the carrier problem as a perplexing factor to public health administration.

Procedures Employed by the Laboratories of the Departments of Health in the Various States and Some of the Larger Cities of the United States in the Sero-Diagnosis of Syphilis as of December, 1935

E. L. WEBB AND T. F. SELLERS, M.D., F.A.P.H.A.,
Serologist, and Chief of Laboratories, Georgia State Department of Health, Atlanta, Ga.

THE desire to ascertain the methods of procedure used in the sero-diagnosis of syphilis by the public health laboratories over the country, recently prompted the laboratory of the Georgia State Department of Health to send a questionnaire relating to this work to the departments of health of all the states and 15 of the larger cities.

Their coöperation in this study was splendid indeed as replies were received from all of them. A compilation of a portion of this information is presented below. The wording of the replies has been closely followed without assuming to name the procedures.

States	*Complement-Fixation*	*Precipitation*	*Annual No. Specimens*
1. Alabama	Kolmer	Kahn	85,000
2. Arizona	No serological diagnosis of syphilis		
3. Arkansas	3 antigen-antisheep	Kline	20,000
4. California	Kolmer	Kahn	36,000
5. Colorado	None	Kahn	15,000
6. Connecticut	2% chol. ant. 4 hr. fixation in refrig. sheep hem. system	Kahn	50,000
7. Delaware	Kolmer	Kahn	6,100
8. Florida	None	Kahn	132,000
9. Georgia	Kolmer	Kahn on request	75,000
10. Idaho	Kolmer	Kahn	18,000
11. Illinois	Kolmer on request	Kahn	100,000
12. Indiana	Kolmer	Kahn and Kline	49,000
13. Iowa	Kolmer	Kahn	39,000
14. Kansas	Kolmer	Kahn	30,000
15. Kentucky	Similar to Kolmer: multiple antigens used	Kahn technic using Kline antigen	65,000
16. Louisiana	Original Wassermann modified. Two antigens used	Kahn, Kline and Johns occasionally	10,000
17. Maine	None	Kahn	12,000
18. Maryland	Kolmer (quantitative)	Kahn	23,000
19. Massachusetts	None	Hinton	140,000

States	Complement-Fixation	Precipitation	Annual No. Specimens
20. Michigan	None	Kahn (standard and presumptive) Kline as supplementary	114,000
21. Minnesota	Kolmer	Kline	135,000
22. Mississippi	Old Hygienic Laboratory	Kline-Young	45,000
23. Missouri	None	Kahn	17,000
24. Montana	Kolmer	Kahn	13,000
25. Nebraska	Own modification	None	30,000
26. New Hampshire	Kolmer	Hinton	15,000
27. New Jersey	Modified Kolmer 4 hr. fixation in icebox	Kahn on positive Wassermann	50,000
28. New York	New York State Standardized method	Making comparative study of several	125,000
29. New Mexico	Kolmer	Kahn	20,000
30. Nevada	Kolmer	Kahn on request	4,000
31. North Carolina	New York City method of 1918	Meinicke	110,000
32. North Dakota	Kolmer	Kahn	6,500
33. Ohio	Kolmer (4 hr. fixation in icebox)	Kahn	82,500
34. Oklahoma	Modified Kolmer (Short incubation)	Kline	50,000
35. Oregon	None	Kahn Standard and Presumptive	12,000
36. Pennsylvania	Own modification	Kahn on request	80,000
37. Rhode Island	Kolmer	Kahn and Hinton	8,000
38. South Carolina	Wassermann Park and Williams: Pathogenic Organisms	Kahn	60,000
39. South Dakota	Own modification	Kahn	6,500
40. Tennessee	Kolmer	Kahn	40,000
41. Texas	Kolmer	Kahn	39,000
42. Utah	Kolmer	Kahn	9,000
43. Vermont	Modified New York City Method	None	6,000
44. Virginia	Craig (modified)	Kahn on request Routinely in Branch Laboratories	60,000
45. Washington	Kolmer	Kahn	24,000
46. West Virginia	Kolmer (check in doubtful cases; Colloidal gold on spinal fluids)	Kahn	44,000
47. Wisconsin	Own modification	None	120,000
48. Wyoming	No state laboratory		
49. Army Med. School	Craig modification	Kahn	18,000
50. Navy Med. School	Neil modification	Kahn Kahn official test for Navy	3,600

Cities	Complement-Fixation	Precipitation	Annual No. Specimens
1. Baltimore	Modified Wassermann (not specified)	Kahn when indicated	25,000
2. Boston	Wassermann (not specified; two antigens used)	Kahn and Hinton on request	15,000
3. Buffalo	N. Y. State standardized method approved	Kahn and Kline on request	40,000

Cities	*Complement-Fixation*	*Precipitation*	*Annual No. Specimens*
4. Chicago	Wassermann (not specified)	Kahn	57,000
5. Cincinnati	Wassermann (not specified; icebox fixation)	Kahn	12,000
6. Cleveland	None	Kline and Young, and Kahn	20,000
7. Detroit	None	Kahn (standard and presumptive)	45,000
8. Los Angeles	Kolmer	Kahn	26,000
9. Memphis	None	Kahn (Kline used as check)	40,000
10. New Orleans	Wassermann (not specified; two antigens used)	None	18,000
11. New York	New York State method	Kline	230,000
12. Philadelphia	Wassermann (not specified)	Kahn	25,000
13. Pittsburgh	Wassermann (not specified)	None	8,000
14. San Francisco	Kolmer	Kahn	34,000
15. St. Louis	None	Kahn	32,000

This study embraces the activities of the laboratories of 46 of the states and 15 of the larger cities, together with the Medical Schools of the Army and Navy, in the serology of syphilis on nearly 3 million specimens annually. Two states do not offer this service.

Eleven of these 63 laboratories, representing 579,000 specimens, are using flocculation tests only, and 5 representing 182,000 specimens are using the complement-fixation test only. Both kinds of tests are employed in 47 in the examination of 2,038,000 specimens.

Twenty-four of the laboratories using complement-fixation employ Kolmer's method, and 5 are using modifications thereof. The others are divided as follows: Method not specified, 11; own modification, 4; New York State Method, 3; Craig Modification, 2; Neil Modification, 1; original Wassermann modified, 1; Hygienic Laboratory Method, 1.

The Kahn test is relied upon alone in 8 laboratories and is used in 41 others of this group. The Kline test is employed in 10, Hinton in 3, and Meinicke in 1.

The combination of the Kolmer and Kahn methods is apparently the more popular, being employed in 25 of these laboratories.

Milwaukee's Well Advertised Gastrointestinal Epidemic

JOHN P. KOEHLER, M.D., F.A.P.H.A.
Commissioner of Health, Milwaukee, Wis.

DURING the end of March, 1936, Milwaukee received an unusual amount of publicity in the newspapers throughout the United States on account of an epidemic of gastrointestinal disease.

While the epidemic was very extensive, the estimate of 120,000 cases by a newspaper correspondent, was very generous. The 2 deaths which were announced in the newspapers, were not due to the epidemic, but to other more serious causes, although each death certificate did mention gastrointestinal influenza as the contributory cause. The epidemic was most noticeable among school children where the absenteeism increased from a normal of 5 per cent to 15 per cent over a period of 3 or 4 days. The majority of the adults who suffered from the ailment, were not sick enough to remain away from their regular occupation.

The symptoms usually started with nausea followed by vomiting and in most cases by diarrhea. Most persons felt relieved as soon as they had vomited. A few had fever and were compelled to remain in bed for 2 or 3 days. Such patients had the symptoms and appearance of what is commonly called la grippe. The symptoms in many patients were very similar to those present in an attack of acute food poisoning.

Nose and throat cultures of patients showed nothing abnormal. Stool examinations were not made because patients were not sick enough to go to hospitals nor sick long enough for the Health Department to make arrangements for the collecting of stools. According to the experience of others, such stool examinations probably would not have had any diagnostic value.

Some physicians reported an increase of appendicitis cases following the epidemic. Since appendicitis is not a reportable disease, there is no way of knowing how much of an increase occurred excepting as it is reflected in the mortality rate. Fifteen deaths from appendicitis were reported during the month of April, compared to a total of 22 for the 3 previous months, 5 for May, and an average of 7 deaths for April, during the last 5 years.

The Milwaukee epidemic was no different from other gastrointestinal disturbances occurring in other communities, with the probable exception that it was somewhat more extensive and explosive than is generally the case. However, due allowance must be made for the fact that other communities may not have had their epidemics during a bitter municipal election campaign and in that way escaped unnecessary publicity. The first reports to the Milwaukee Health Department of gastrointestinal disturbances came from pediatricians during the last week of February. They reported that babies and younger children were suffering from diarrhea. The city water at that time had a bacteria count of zero to

2 per c.c. with an occasional 10 c.c. tube showing gas in 48 hours, but no confirmation for *B. coli.* The water at this time had a bad taste and odor, which had never been noticeable before. The taste and odor were similar to those found in old shallow wells with decayed wooden casings. No turbidity was noticeable.

It was assumed that the melting of the winter's accumulation of snow and the breaking of the ice which had covered the lake for a long period, had something to do with the unusual taste and odor. The water showed a few algae which may have contributed to this unusual taste and odor. The Milwaukee River, which empties into Lake Michigan, about 4 miles south of the water intake, was very high the last part of February and the first part of March due to the spring thaw. The Sewage Disposal Plant, which treats all of Milwaukee's normal flow of sewage, discharges its effluent into Lake Michigan at the outlet of the Milwaukee River. Beginning with March many reports of gastrointestinal cases came to the Health Department from families which were inclined to blame the drinking water.

Since the drinking water showed absolutely no evidence of pollution, it was always defended by the Health Department. The complaints against the drinking water continued to increase gradually, even after the obnoxious taste and odor had disappeared. Nothing in the examination of either the raw or the chlorinated water, indicated any sign of pollution until the afternoon of March 24, when the bacteria count rose from an average of 3 per c.c. to 61 per c.c. with four of the five, 10 c.c. tubes showing gas in 48 hours. On March 25, the morning and afternoon bacteria counts were 52 and 84 respectively, with five 10 c.c. tubes showing 48 hour gas and confirming for *B. coli.* As soon as this report was available, which was on the morning of March 27, the public was notified of the situation and directed to boil the drinking water. On about the same day, the gastrointestinal cases increased to epidemic proportion. The peak of the epidemic as nearly as could be determined, occurred on March 30.

After March 27, the water began to improve very rapidly. On April 3, the bacteria count was 3 per c.c. and no gas in any of the tubes. The only confirmation for *B. coli* was three out of five and two out of five 10 c.c. tubes of the morning and afternoon samples of March 25. The order to boil the drinking water was not lifted until the morning of April 7, when the bacteria count was 1 per c.c. and there was no 48 hour gas in any 10 c.c. tubes.

Naturally, all during this time, the most important question to be answered by the Health Department was whether or not the drinking water was responsible for the epidemic. Circumstantial evidence certainly pointed toward the drinking water. The Health Department, after analyzing all of the various available evidence, decided that the drinking water was not responsible for the epidemic. This position, obviously, seemed very inconsistent to many people because it was difficult for them to understand why the Health Department's order to boil the drinking water and the epidemic appeared simultaneously, if there was no connection between the two.

The fact that some of Milwaukee's suburbs which had their own water supply, claimed to be free from the epidemic also made it very difficult to absolve Milwaukee's drinking water. Some of the reasons that prevented the Health Department from blaming the water when the epidemic first appeared are as follows:

1. Records show that the so-called gastrointestinal influenza appears periodically in every community and never has been related to any particular water supply.

2. Many gastrointestinal cases had been reported for weeks before the peak of the epidemic arrived and long before the drinking water showed any evidence of pollution. The fact that *B. coli* was present in the water for only 1 day when the epidemic began, scarcely seemed serious enough to warrant such an extensive outbreak of gastrointestinal trouble, especially when the bacteria count and turbidity were both very low and when chlorination was effective at all times.

3. Only rarely did several members of the same family become ill at the same time. Usually a day or two intervened as is the case when you have personal contact infection in homes.

4. The fact that other communities near Milwaukee having their own water supply reported no substantial increase in gastrointestinal ailments, was not given much consideration because Milwaukee has had other epidemics not in any way related to drinking water which other communities near Milwaukee escaped at least temporarily.

5. Reliable information from other cities showed that Milwaukee was not the only city experiencing an increase in gastrointestinal disease.

6. The Health Department knew of several persons who were very ill with the prevailing gastrointestinal disturbance, who stated positively that they had been drinking nothing but spring water for at least a week previous to their illness.

Additional reasons which have been established subsequent to the epidemic, that make it difficult to believe that the drinking water had anything to do with it, are as follows:

1. At least 6 large institutions in and outside of the city using city water, entirely escaped the epidemic due to their isolation. One orphanage with 250 children and 50 sisters, was entirely free from the ailment, although they all drank city water and did not boil it until requested to do so by the Health Department.

2. Several of the schools in the outlying districts were comparatively free from the disease due to their isolation.

3. The survey made by the Health Department nurses showed that families using spring water had just as high a percentage of gastrointestinal cases as those drinking lake water. They also obtained the information that at least 50 per cent of all patients interviewed, had contracted the disease 3 or more days after they had used nothing but boiled or spring water.

4. Although the Health Department nurses reported that 95 per cent of the people either boiled the water or drank only spring water on and after March 27, the peak of the epidemic was not reached as stated previously until March 30, and subsided gradually. Even as late as April 22, a considerable number of cases were reported in one school.

5. Only 3 typhoid fever cases were reported to the Health Department from January 1 to February 6. No case has been reported from February 7 to May 15. From January 1 to May 15 there have been only 6 deaths from gastroenteritis in children under 2 years of age, which is the lowest number of deaths for this period in the history of the Health Department.

6. Eye, ear, nose and throat specialists reported an increase following the intestinal epidemic, of otitis media and other ailments associated with upper respiratory infections.

When the drinking water is responsible for disease, health officers should not hesitate to admit it. On the other hand, we should not be willing to blame the drinking water merely because it appears to be the easiest way out of it. The average individual will nearly always blame something that he has drunk or eaten whenever he has some gastrointestinal disturbance, but that is no reason why the family physician or health officer should agree with such a diagnosis. Blaming the water supply of a community for an epidemic is a very serious matter and should only be done when the blame can be definitely established. If we are able to have periodic extensive epidemics of colds due to a virus, it is not difficult to believe that a virus may also be responsible for other types of epidemics.

Incidence and Severity of Hookworm Infestation in East Texas

R. G. UPTON
Professor of Biology, Stephen F. Austin College, Nacogdoches, Tex.

THE Hookworm, *Necator Americanus*, was first described by Stiles [1] in 1902. Following Stiles's discovery, a great deal of investigation was carried on by the International Health Board in the interest of public health and by Kofoid [2] in 1918 in the interest of the army. Since that time little investigation has been made in Texas, and only a few surveys have been completed in other southern states. The 1927 *Annual Report* of the International Health Board [3] stated that the hookworm problem in the South had been solved. Stiles [4] pointed out that this is a fundamental error, and is partly responsible for the lack of inquiry and lack of interest in this important field of parasitology.

Much more valuable work can now be done by use of newer methods. Some modifications of Kofoid's [5] or other salt flotation methods give a larger number of positives where the infestation is light. The newer methods of quantitative estimation by counting the number of eggs per gram of feces have enabled workers to tell whether the patients carry a small or large number of worms. While these newer findings are not directly comparable with the older, it is generally supposed that the degrees of infestation which are now found are on the whole lighter than those of 10 or 20 years ago; however, recent papers [6, 7, 8] do not support the conclusion that the hookworm problem is solved.

The present study was made during the winter months of 1932 and 1933 in 5 East Texas counties as given in Table I. Of 1,883 pupils examined, 1,751 were white and 132 colored. There were 614 whites, or 35 per cent, infested, but only 2, or 1.5 per cent, of the 132 colored. Of the total number examined, 27, or 1.4 per cent, were infested with dwarf tapeworm, *Hymenolepsis nana;* 12, or 0.6 per cent, were found to have a double infestation of these two parasites. Few other parasites were found.

Table I shows the percentage of infestation for each school district. The number examined in some was not large enough to be a very valuable index of that community. On the whole, the data agree with the findings of 20 years earlier in regard to geographical location, condition of soil, and higher or lower economic levels. The total average of 35 per cent infestation for the entire study of whites is somewhat deceiving, because some of the poorest sandy-land districts, located in the river bottoms or nearby, show as high as 80 per cent infestation for those examined. In the redland districts the infestation ran below 10 per cent in some cases. These districts have improved farms, little timber, and better living conditions, therefore a higher economic level.

Of the positive cases, 237 were studied by the Caldwell and Caldwell [9] Quantitative Method. Where the largest number of cases occur, more heavily infested cases are found. Where the percentage of cases is low, the infesta-

TABLE I

SUMMARY OF HOOKWORM EXAMINATIONS IN EAST TEXAS

During January, 1933, the Texas State Board of Health published in mimeograph form the following summary of the work done

Data for 1932

	Number Examined	*Hookworms Found*	*Percentage Infestation*
1 Negro school	132	2	1.5
5 town schools	353	37	10.0
16 rural schools	341	163	48.8
Total specimens examined	826		

About 2 per cent of *H. nana* found; less than 1 per cent all others

Data for 1933 and 1934

School	*County*	*Number Examined*	*Number Positive*	*Percentage of Positives*	
a	Angelina	40	6	15.0	
a	Nacogdoches	50	12	24.0	
b	"	21	11	52.3	
c	"	55	7	12.7	
a	Panola	14	1	7.1	
b	"	28	12	42.8	
c	"	53	30	56.6	
d	"	44	3	6.8	
e	"	14	9	6.4	2 dwarf tapeworms
f	"	45	1	0.2	3 dwarf tapeworms
g	"	5	1	2.0	
a	Sabine	62	52	83.8	Some are heavily infested
b	"	134	24	17.9	
c	"	88	30	34.0	7 dwarf tapeworms
d	"	28	14	5.0	
a	San Augustine	61	23	37.7	
b	" "	69	12	17.4	
c	" "	102	64	62.7	
d	" "	12	5	41.6	2 dwarf tapeworms
e	" "	46	39	84.6	Most infestations rather heavy
f	" "	31	11	35.4	
g	" "	49	13	26.5	
	Totals	1,151	390	33.9	

About 2 per cent of other parasites besides hookworms were found.

tion is very light to light. The methods of quantitative estimation have not found their way into general practice, and few of our state boards of health are now using these methods in their laboratories. Nevertheless, it is a very valuable bit of knowledge to the practising physician to know the degree of infestation, as light cases may be given only 1 or 2 treatments; whereas, heavy cases need further treatments. Where quantitative estimations are used, it might be well to reëxamine light cases after 1 treatment.

The accompanying data (Table I) contain a summary of the work done

in 1932, published in mimeograph form by the Texas State Board of Health, and a summary of work done in 1933 and 1934, giving the total number examined in each school district, the number of hookworm infestations, the percentages of infestations, and the number having dwarf-tapeworm, *Hymenolepsis nana.*

Analysis of degrees of infestations is given in summary only for all of the positive cases studied, as follows: Very light 54.2 per cent; light 27.9 per cent; moderate 16.9 per cent; and heavy 1.0 per cent.

There is no close agreement among quantitative workers about what constitutes the different groups of infestation. The divisions here are made according to the method of Smillie and Spencer [10] in their Alabama work. The first group, very light, contains all those who have an egg count per gram feces below 600, which indicates from 1 to 25 worms; the second group, light, has an egg count of from 600 to 2,099, which indicates from 26 to 100 worms; the third group, moderately infested, has 2,100 to 11,099 eggs per gram feces, which corresponds to 101 to 500 worms; the fourth group, heavily infested, runs from 11,100 or more eggs per gram of feces, and indicates over 500 worms. Chandler [11] states that it is better to report egg counts only than to report worm load, as the latter introduces another variable element. We have chosen to report both, for the purpose of general information.

These 4 classification groups give a valuable indication of the degree of infestation in the East Texas counties studied.. It is assumed by some that only light infestation still exists. In one school 12.5 per cent of the positives were heavily infested; in another, 44.7 per cent of the positives were moderate infestations. A large number of cases fall in the light and very light columns.

Investigators disagree on the amount of injury, mental and physical, done by the light and very light infestations. The writer is continuing a study of this problem, and will report later further findings on mental and physical retardation. Data on several hundred cases have been collected and will be analyzed and reported later.

It should be noted that this study has been made for scientific information and not for comparison between districts or counties. It indicates that widespread hookworm infestation exists in East Texas, that there is between 1.5 per cent and 2.0 per cent infestation of dwarf tapeworm, *Hymenolepsis nana,* and that a few children harbor both parasites.

The quantitative estimation of the degree of infestation adds important information concerning conditions in East Texas. It is hoped that this study may be an incentive for further work in solving the problem of intestinal parasites in East Texas and in all the southern states.

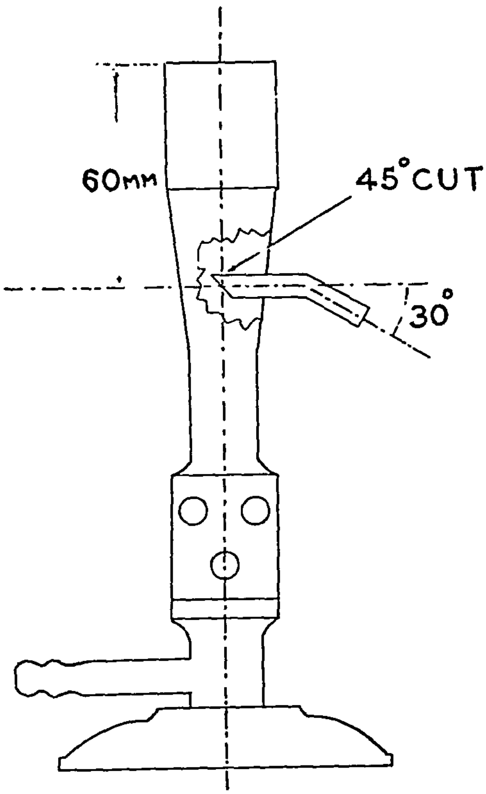
A Meeker Burner With Auxiliary Flame For Bacteriological Use

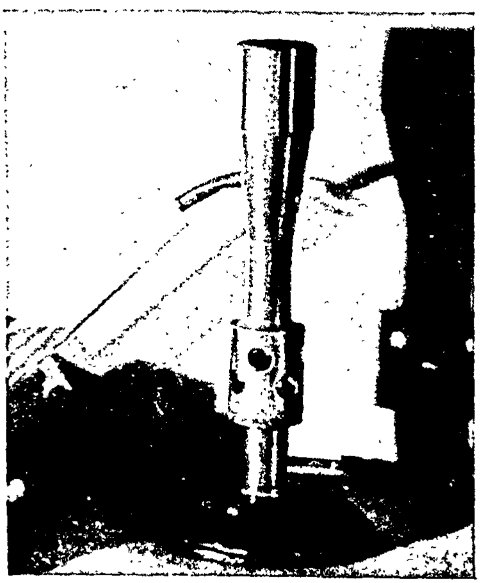
MATTHEW E. HIGHLANDS AND PHILIP K. BATES, PH.D.

Department of Bacteriology and Biochemistry, University of Maine, Orono, Me.; and Department of Research and Technology, United Drug Company, Boston, Mass.

THE usual flaming of the mouth of a tube or flask containing bacteriological culture media will not satisfactorily remove the fibers of cotton which frequently adhere inside the neck during the tubing and sterilization. In work with pathogenic organisms, or in disinfectant testing, the infection of these fibers when the medium is inoculated offers a possibility of danger to the worker as well as inaccurate results in the experiment. An attachment of the type illustrated offers an easily constructed device for the burning of any cotton fibers inside the neck of a test tube or flask.

The burner is constructed from a Meeker burner and a short length of ¼″ copper or brass tubing. The piece of tubing should be about 3″ long, with one end cut perpendicular and the other at 45° to the axis. The tube is bent at an angle of 30° at about





1″ from the end in the manner shown in the diagram. The tube is soldered into a ¼″ hole in the burner about 2⅜″ from the top. The end cut at 45° should be at the center of the burner.

The side arm deflects a portion of the gas-air mixture which gives a flame similar to that of a microburner but deflected downward at an angle convenient for use. A small stopper or cap may be placed over this tube when the auxiliary flame is not desired.

Notes on Swimming Pool Sanitation Control

W. SCOTT, JOHNSON
Sanitary Engineer, St. Louis Health Division, St. Louis, Mo.

THE sample collecting technic and and residual chlorine standards developed for better control and operation of swimming pools have undergone marked changes in the last few years. These changes were based upon experimental results and have now been included in the 1935 Report of the Joint Committees on Bathing Places of the American Public Health Association and the Conference of State Sanitary Engineers.[1] The important changes recommended are the use of sodium thiosulphate treated bottles for collecting swimming pool samples for laboratory analysis, and the maintenance of a minimum of 0.4 and 0.7 p.p.m. residual chlorine in the pool water during use, depending on whether chlorine or chloramine is used. It is presumed that those concerned with swimming pool sanitation will be interested in viewing critically the significance of these changes. To this end, the actual effect of these changes as reflected by the bacteriological results on samples collected from typical pools, indoor and outdoor, both modern and antiquated in construction and equipment, during a 2 year period of observation may be of interest.

Five 10 c.c. portions of each sample collected were examined for *B. coli*, partially confirmed on endo, and a plate count was made of each sample. All bacteriological analyses were made according to *Standard Methods*. A test for residual chlorine was made of pool water at the time each sample for bacteriological analysis was collected. The pH of the pool waters for the 2 year period was as follows: 55 per cent of pools averaged 8.0 to 8.4 pH, 42 per cent averaged 7.1 to 7.9 pH, and 3 per cent, or 1 pool, averaged 6.9 pH.

Preparations of the bottles for sampling was accomplished according to Option 1, Report of the Joint Committees in Bathing Places, except that sterile sodium thiosulphate solution was added aseptically after the bottles were sterilized.

During 1934–1935, 1,075 samples were collecetd from swimming pools in treated bottles, and an equal number were collected simultaneously in un-

Annual Science Exhibition

THE annual meeting of the American Association for the Advancement of Science and its Associated Societies will be held in Atlantic City, December 28, 1936, to January 1, 1937. This Association with an individual membership of 18,000 has associated or affiliated with it over 150 other scientific societies. Its annual meetings bring together representatives of all sciences.

The leading feature of the meeting in Atlantic City will be the Annual Science Exhibit which is expected to be the most successful in the history of the association. The leading American scientists have been generous with their time and money in building up the exhibition to its present distinction. It offers an objective means for enhancing the belief in the intelligence and integrity of manufacturers in the utilization of science. To the scientists in various fields, apparatus, equipment, and demonstration are more meaningful than formally presented papers. Thus the breach between the branches of science is lessened and the exhibition becomes an asset toward democracy.

Participation in this exhibit will be welcomed. Address communications to F. C. Brown, Director of Exhibits, American Association for the Advancement of Science, Smithsonian Institution Building, Washington, D. C.

EDITORIAL SECTION

A GREAT MEDICAL LIBRARY

WE wonder how many of our readers, and especially members of our Association, know the history of the Army Medical Library, or, as it was called prior to 1922, the Library of the Surgeon General's Office, and are familiar with the treasures it contains. How many of us were aware that this year marks the 100th birthday of this Library, not only one of the foremost scientific institutions of the world, but the largest medical library in existence? We, the youngest of the great nations of the world, have in 100 years outstripped all others in the collection of medical literature. Indeed, we might say that this has been done practically within 75 years.

In 1836, Surgeon General Lovell had a small collection of books in his office, but it grew very slowly until Colonel John Shaw Billings came into the picture at the close of the Civil War in 1865. In this year the first printed catalog of the Library appeared, listing 2,253 volumes—602 titles under 11 topical subdivisions. At present the Library contains 941,181 volumes, showing the truth of the statement that most of the work has been done within 75 years.

Not only is it the largest library in the world, but it is one of the best. Only some 600 medical incunabula are known, and of these, the Library owns 450, many of them first editions, the greatest number in any library in the world, and a collection which bears comparison with that of any library anywhere. Of some works, the Library has the only known copy. Of rare books published after 1500, its collection is one of the best, and it possesses 150 early medical manuscripts of great value. The oldest publication it has is Johannes Gerson's *De pollutione nocturna*, printed in Cologne in 1467.

Of a number of rare books, the Library owns several successive editions. Some of these it is practically impossible to obtain now. Indeed, it is a marvel that starting the collection as late as 1865 these rare and valuable books were obtained

at all, especially as the appropriations for purchase have always been relatively small—not at all in comparison with the funds granted to the Library of Congress. The Army Medical Library has some 15 per cent as many volumes as the Library of Congress, but its annual appropriation for purchase is only about 9⅛ per cent as large.

The Library contains a more complete file of French theses than does the great library of the Faculty of Medicine of Paris. It has a great collection of authors' presentation copies, autographed.

This Library is open to the physicians of the United States, and it is safe to say that practically no medical work of importance is written without consulting its files, which serve also the medical officials of the Army, Navy, and Public Health Services. Certain publishing houses keep a number of employees constantly in the Library doing bibliographical research, abstracting and translating, and many textbooks have been written or revised almost entirely in the Library building, though this fact is seldom mentioned.

No one can have a fair idea of this Library unless he sees it intimately and works in it. Dr. William H. Welch once said that the four great contributions of America to medical science were: "1. The discovery of anaesthesia. 2. The discovery of insect transmission of disease. 3. The development of the modern public health laboratory, in all that the term implies. 4. The Army Medical Library and its *Index Catalogue*, and this library and its catalogues are the most important of the four."

Similar expressions have come from a number of well known men. Adami, of McGill University, in writing of the *Index Catalogue* and *Index Medicus*, said: "It is difficult to realize what service those two publications have been to science the world over, or what has been the influence also to medicine the world over, of the existence of the marvelously progressive Library of the Surgeon-General's Office, and its service in bibliographical search. . . . (It is) regarded everywhere as the model medical library. . . . I would go so far as to say that the outstanding service to medicine by the United States has been this Library with its publications."

Billings once said, "Books are properly compared to tools of which the index is the handle." He carried out this idea in furthering the *Index Catalogue* of 48 ponderous royal octavo volumes (compare with the Catalogue of 1865 with 2,253 volumes), and later the *Index Medicus*. These two publications have had almost as much praise as the Library itself. The late Sir William Osler said of the *Index Catalogue*, "Its preparation is Gargantuan," and it is recognized that in no other field of knowledge is there a work comparable to this, the world's standard of medical bibliography. In 1935, Bulloch[1] said, "Among catalogues the Surgeon General's is regarded by the authorities at the British Museum as the greatest ever achieved. It has the great virtue of being a subject index, unlike that of the British Museum, which is a name index only. The story of its construction is not as well known as it ought to be." When a change in the form of the *Catalogue* was discussed, the librarian of the Royal Society of Medicine of London said, "The possibility of being deprived of the *Catalogue* in its present form is horrible to contemplate," and Sir Humphrey Rolleston, at that time Regius Professor of Physic at Cambridge and President of the Royal College of Physicians, said, "The change would be a very serious loss to all those who read or look at the scientific side of Medicine, and would, for them, bring about a condition of affairs resembling that in the first half of the last century."

One would naturally say that this invaluable and irreplaceable collection must be housed in the finest of buildings, with every convenience for the use of its treasures, and absolutely fireproof. What are the facts? In 1885, $200,000 was appropriated for the building, and in 1887, the Army Medical Library and Museum was opened to the public. It is so cramped for space that when new books are added the old ones must be taken out and many are stored in the basement. Year after year efforts have been made to obtain a proper Library building. In 1919, a site was purchased in the Army Medical Center in Washington, but up to the present time the building has not materialized.

We wish we could give here a sketch of the librarians who have served this wonderful collection and those who have been responsible for the equally marvelous catalogues and indices. We cannot select one above another, but must mention Dr. Robert Fletcher, the Father of the *Index Medicus,* without whom this publication might possibly have never come into existence. In 1910 he was awarded the gold medal of the Royal College of Surgeons, which during a century has been conferred on but 11 others.

Perhaps the majority of the profession has not recognized that this was the centennial of this great Library, which is one of America's best known and most valuable possessions. We believe that Major Edgar Erskine Hume, the present Librarian, has performed a distinct service in giving an account of the Library,[2] his predecessors in the office, and especially the history of Dr. Billings, who, although he did not found the Library, is chiefly responsible for its being what it now is. We wish we could place this history in the hands of all our readers. We hope that this review, taken from the article by Major Hume, will stimulate the interest of those who have not yet made use of the Library. Something of what it is may be gathered from this brief review, but especially from an address given in 1881 by Dr. Billings. Even at that date he was able to say, "If the entire medical literature of the world, with the exception of that which is collected in the United States, were now to be destroyed, nearly all of it that is valuable could be produced without difficulty."

NOTE: We have in this country other notable collections of medical books, some of them generally unknown. In 1920 there appeared *The Dawn of Modern Medicine*, by Albert H. Buck, M.D., a volume for which the William Chauncey Williams Memorial Publication Fund was responsible. In his preface he speaks of the difficulties he had encountered. Although he made a search in Europe, he failed to find the sources of trustworthy information which he thought necessary. He was disposed to abandon his writing of this book altogether when he received a letter from the librarian of Transylvania College, Lexington, Ky., telling him of a collection of medical works which had been purchased in Paris in 1819, concerning largely the years from 1760 to 1830. He moved to Lexington and lived there for 7 months, during which he wrote the book, taking his material almost entirely from this splendid and rare collection.

SCARLET FEVER

THE discussion of scarlet fever in its various forms continues. In the Borough of Chelmsford, England, in 1935, there occurred an extensive outbreak which is believed to have involved some 2,000 people, though only 360 cases were reported in the Borough, and some 120 in the adjacent district. The outbreak was explosive in character, most of the cases having occurred within 10 days. Almost all of them were traced to Dairy A, which handled milk from a number

of farms, which were found to be free from suspicion, with one exception. On this place there was one milker who had been working while suffering with a very bad sore throat from August 21 to 23 inclusive. It was during these days that the main infection of the milk supply was evident.

The particularly interesting feature of this outbreak was that the great majority of the cases, 1 in 5, did not show any rash. The milker to whom the outbreak was attributed also failed to show a rash. Extensive typing showed that the organism responsible for the outbreak was a hemolytic streptococcus type 2, which was isolated from the second sample of milk examined. It was found that the milker who suffered from the sore throat without rash also harbored the hemolytic streptococcus type 2.

During the time of the outbreak a cow with acute mastitis was found, but as it did not harbor the same type of streptococcus it was exonerated. Incidentally, it is now well established that the streptococcus causing acute mastitis in cows in the great majority of instances is not pathogenic to human beings.

The reporter who studied this outbreak believes that the term "scarlet fever" in a misnomer and points out that if attention had not been concentrated on rash as a diagnostic feature of scarlet fever, the outbreak would have been recognized much earlier and probably some of its worst features avoided. The absence of the rash was also responsible for the fact that so few of the large number affected were reported, though unquestionably all suffered from the same disease, as shown by bacteriological examination.

The outbreak demonstrates once more, what has been shown so often, that the rash, which has for so many years been considered typical of scarlet fever, cannot be depended upon for diagnosis.

POLIOMYELITIS

POLIOMYELITIS continues to give much concern to the health officers of the country. Since the big epidemic in Los Angeles in 1934, it has advanced east and up the Atlantic seaboard. Accounts of the epidemic in Los Angeles attracted much attention at our Annual Meeting in Pasadena in 1934. At our Annual Meeting in Milwaukee in 1935, there was much discussion of the vaccines proposed to control the disease; and before the Southern Branch of our Association in St. Louis, the same year, there was presented a most valuable symposium on the disease in North Carolina, Virginia, Kentucky, and Tennessee, as well as reports on the use of the vaccines of Brodie and Park, and Kolmer. During the year 1935, considerably more than 10,000 cases were reported in this country, the incidence varying from 258 per 100,000 in Rhode Island, to 1 in Idaho, and 2 in Georgia, Oklahoma, and Wyoming. The year 1936 has been marked by quite extensive outbreaks in several of our southern states, Alabama leading in the number of cases.

The menace has been such as to lead the Essex County Health Officers Association of New Jersey to form a poliomyelitis committee, which has sent a questionnaire to a group of cities throughout the United States. Twenty-six answers were received from the health officers of the largest cities. As might have been expected, the answers varied widely. Some health officers said frankly that so little was known about the disease that they were reluctant to commit themselves. The replies have hardly furnished a basis for constructive regula-

tions, but are useful in indicating the differences of opinion among those officials charged with preventing and controlling epidemic diseases.

As to the methods of spread in poliomyelitis, there was practical unanimity that the path of infection was through the upper nasal and pharyngeal surfaces, and that the virus reached the individual by contact, usually through sneezing, coughing, kissing, and droplet infection. A small minority were inclined to look with suspicion upon dishes, some foods, and articles of general use.

In discussing the autumnal prevalence of the disease, there was difference of opinion, some health officers pointing out that in their sections the autumn was not the season of greatest prevalence. It may be noted here that, in Alabama particularly, the disease has been prevalent in June and July of this year, and this was true for North Carolina and Virginia in 1935. However, the opinion was general that the collection of adults and children at resorts during summer vacations furnished the environments in which contagion was most favored, and that the outbreaks were likely to occur when these people returned to their homes and schools. It does not appear that the facts fit the theories entirely.

Several health officers laid stress on individual susceptibility, and increased susceptibility brought about by fatigue, diet, constitutional factors, climatic conditions, cellular immunity, etc., while one health officer, who has had a large experience, considered dosage of the virus of importance, holding that a transitory exposure was not dangerous, and that "continued exposure was almost always necessary to cause infection."

The health officers were far from being at one concerning regulatory requirements. A decided majority opinion opposed the closing of schools except for the grades for children under 7 years of age. Postponement of the opening of schools in the presence of an epidemic was widely favored. There was considerable division as to the legal closing of movies, theatres, fairs, swimming pools, etc.

The hospitalization of all cases was generally favored, not only on account of giving the patient a better chance for recovery, but also for avoiding alarm.

The general use of throat and nose sprays containing materials which have been suggested, such as sodium alum, tannic acid, and picric acid, was not generally approved of, though some officers advocated studies under proper control.

The Essex County committee drew up a set of regulations embodying what they believe to be the best practice in view of experience and present knowledge. Hospitalization of all cases is advised. Immediate report by physicians to the local health department of all cases of paralysis, as well as those showing fever, headache, vomiting, and stiffness of the neck is urged. Services of a diagnostician should be available when possible. The opening of schools should be postponed during an epidemic. Playgrounds should be closed or else used for separate classes during recess periods, with no mixing of grades. Swimming pools should be kept open but regularly chlorinated during epidemics. Contacts under 16 should be put under observation for at least 14 days. The public should be advised against allowing children under 12 years of age to attend circuses, fairs, picnics, and movies.

While this questionnaire and the replies received show our lack of exact knowledge in regard to a number of essential facts, it is useful in calling attention to the divergence of opinion and practices now in effect. New Jersey will doubtless benefit by having more uniform methods of observation and control.

PUBLIC HEALTH EDUCATION*

National, state, and local agencies . . . public and private . . . commercial groups . . . publishers . . . all who issue health education material . . . are invited to read *Your Part at New Orleans.*

Your Part at New Orleans—The part of national, state, and local health agencies, commercial groups, publishers, and all others doing health education, or supplying health education materials is vital to the full success of Health Education Headquarters at New Orleans.

According to present plans there will be displayed a generous array of helps in the technical side of health education, both in the schools and in the communities.

Then there will be shown various classified collections of printed and other materials used or made available for use by health agencies.

Your part is to make possible extensive additions to the collection of classified materials.

National and state agencies, commercial agencies, etc., *which issue material for others to use* are invited to make up specimen sets, with prices and other detailed information, prepared in portfolio form. *All such portfolios should be forwarded, prepaid, direct to New Orleans.* Please write to the chairman for information as to when and where to ship or to deliver packages.

Those who have exhibits, posters, lantern slides, etc., for sale or loan, should send them direct to New Orleans, *but should write for information as to when and where.*

Graphic displays from all sources will be welcome *if advance information is requested as to when and where to ship or to deliver.*

In addition to the above, local and general agencies are requested to send specimen copies of health education materials (clipped, printed, mimeographed, or otherwise duplicated) *to the chairman in New York.* Such specimens will be assembled in classified portfolios: newspaper articles, photographs, radio talks, bulletins or house organs, exhibits, plays, announcements or catalogues, etc., etc. Please send the above as early as possible.

For information as to when and where to ship please write to the chairman, Evart G. Routzahn, 130 East 22d St., New York, N. Y. Send to the same address the specimens of materials for the classified portfolios.

Individual and Group Conferences at New Orleans—According to present plans, special attention will be given at Health Education Headquarters to conferences with individuals and groups interested in any phase of health education.

Please list your problems and your questions and submit them early in the week.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Likewise kindly come prepared to report on your experiences, your successes, and your failures, if any.

Free Distribution at New Orleans—Space will be provided for free distribution of copies of health education materials, and lists or catalogues of helps and materials issued by non-commercial agencies.

Please write to the chairman in advance for instructions as to shipment or delivery.

Sorry! Our Mistake!—Dr. A. S. Baker, Health Education Adviser, Seattle, reminds us that he is with the *State* Department of Health, not the City Health Department, as stated on pages 737 and 739, July, 1936. Why anyone should have misread the letterhead is inexplicable. Just one of those things!

So Many Had Something to Contribute—That so many health workers have had illustrative experiences is the most striking feature of the symposium on venereal disease publicity.

When we began publication of these reports there seemed to be a widespread belief that both press and radio were closed channels to any wording more frank than "social diseases." Yet the reports as published show fairly general willingness to avoid hypocrisy. But so few health workers had reported the progressive steps taken that such action by a newspaper or station was accepted as being exceptional.

So many have something to contribute on numerous health situations. Widespread alertness among public health workers in reporting what they do and what others do would further the progress of public health activities. Here we have given space to the venereal disease reports partly to illustrate and emphasize the helpfulness of experience shared with other health workers.

As to venereal disease, *Editor and Publisher*, chief journal of the newspaper world, is sympathetic. Give them something to write about by sending marked copies of your local newspapers. Address: Times Building, New York, N. Y.

Why Not Try for Radio "Spots"?—Business seems to be making much of the "spot" or "station-break" announcement, the 30 to 60 second interval between network programs. Some health agencies, and more of varied social agencies, have already discovered the possibilities of these bits of radio time, or possibly, chinks in radio time. The watch company has long illustrated one use of this time. Some of the chest campaigns have made good use of a station announcer for "spot" statements.

The bigger audiences are "on the line," the copy is not so difficult to write, an idea may be pushed a number of times in the course of a few days. But of course alert advertisers are likely to buy the best of the periods.

If you want more on the subject see "Breaks for the Radio Advertiser" in *Advertising and Selling*, 9 East 38th St., New York, N. Y. July 16, 1936. *15 cents.*

Art in Health Teaching—The April-May, 1936, issue of *Baltimore Health News* (Health Department of Baltimore, Md.) was a smallpox issue. Articles and editorials included one on "The Reactions Which Follow Smallpox Vaccination." This was illustrated by a 3 page offset lithographic color plate to

> . . . represent a careful selection of the standard types of reactions which follow smallpox vaccination. They were painted from life by Leon Schlossberg, pupil of Max Brödel, in the Department of Art as Applied to Medicine, in the Johns Hopkins Medical School.

This material has been sent to deans of medical schools in the United States, Canada, and England. Copies of this issue of *Health News* are supplied at *25 cents,* a charge made necessary by the cost of the color plate.

Health Education in a City Health Department—We have all too little in print on what a health department should or could actually do in health education and how to go about it. A 5 page contribution on this subject is "The Educational Work of a Health Department," by Savel Zimand, who says:

While health problems vary with the locality and therefore the educational program must inevitably differ with the community and the individual districts in that community, there are certain basic essentials which will be found in the health department educational program of almost any locality. A comprehensive health department program of education would cover at least two phases: (1) popular health education; and (2) health education for professional groups. Fundamental though school health education is, it is not included here, since in the majority of localities including New York City, this phase is usually regarded as the function of the school authorities, although the official and voluntary health agencies can be of assistance in various ways.

One important function of popular health education is to give the community a general knowledge and understanding of the work of the official health organization. Few people now realize in full the important rôle played by a health department in maintaining the welfare of a city, or the various services it renders which have a direct influence on their own and their family's life. The public should know how a health department functions; its responsibilities; the services it maintains; when and how they may call upon it for help; what constitutes a violation of health ordinances; and to whom such violations should be reported. . . .

Aside from familiarizing the public with the work of the health department, the objectives of a well rounded program of popular education might be summarized as follows: (1) educating the public concerning health conservation, disease communication, and methods of safeguarding health; (2) securing desirable changes in public opinion; and (3) educating the community to utilize the services of a private physician, or if financially unable to pay for such services, to use those of the community's clinics or hospitals.

Mr. Zimand discusses the selection of subjects, and the possibilities in "personal instruction," and "mass education."

Whatever the methods or the subject matter there are

. . . certain fundamental conditions without which they cannot accomplish their purpose. These are *scientific accuracy, emotional appeal, concreteness and simplicity.* In addition, the program must be adapted to a specific audience and presented at an opportune or psychological time. Certain problems are city-wide and others are more local in character.

Written by a big city man yet the ideas pretty generally may have a wide application. In *Public Health Nursing,* 50 W. 50th St., New York, N. Y. July, 1936. *35 cents.* For a reprint write to the author, Department of Health, 125 Worth St., New York, N. Y.

"Warranted Publicity"—Headed by these words the Elizabethton, Tenn., *Star* (July 16, 1936) editorialized as follows:

A neighboring newspaper, which might represent the policy of the majority of newspapers of the nation, falls over backward in a recent editorial in an attempt to avoid using the word "syphilis," despite the fact that the editorial meant absolutely nothing with the word omitted and only conveyed the meaning that the writer of the article knew something which the reader should know but he just couldn't dare to tell it.

The writer winds-up his meaningless hodgepodge of words by stating that "public sentiment may soon demand frank discussion of this subject in the newspapers and public forums." Where has the writer been? Does he know that all New York papers have adopted the policy of writing about the symptoms, causes, and ravages of syphilis and other venereal diseases as they would scarlet fever—only with more emphasis in an attempt to overcome the "ttch, ttch" attitude which has been shown in the past whenever it is mentioned? Does he read the current periodicals which are more and more coming

to realize the dangers that lurk in a secretive attitude toward the diseases and are working to combat the general lack of knowledge about them?

The "shush-shush" attitude is discussed in two paragraphs. Then the editor emphasizes that the *Star*

. . . has made it a practice for some time to carry information concerning this disease. In this issue is one of a series of articles on venereal disease, published through the Carter County Health Department and Carter County Medical Association.

The *Star* did not adopt this policy to create any sensationalism, the manner in which the articles were carried could not possibly warrant this accusation. . . .

Surely the accusation could not be made that a newspaper, the most widely read medium of information in existence, is not the proper thing in which to carry such articles while trial testimony from love balm suits, giving complete details of an intemperate bedroom scene, is run under big heads and played on the front pages of the papers. . . .

Accompanying the clipping Dr. *Franklin M. Foote, Carter County* Health Department, says:

So that you will know that we hill billies have a wide awake press, I am enclosing an editorial from the *Star*. As you can see, this followed a brief editorial in a Johnson City paper mentioning a dread disease the health department was treating there, without even mentioning the euphemism "social disease." The accompanying editorial was written without the knowledge of anyone connected with health work purely on the local editor's initiative. Incidentally, I may add that this paper prints all our releases on syphilis and gonorrhea as readily as those on typhoid fever or poliomyelitis or whatnot. This is the third editorial that has appeared within 6 months in this paper concerning the diseases in question. When I presented a baby with gonorrheal ophthalmitis before the county court, the local appropriating body, the story was carried on the front page with "Venereal Disease" in the head.

NEW

The Child—Monthly News Summary, U. S. Children's Bureau, Washington, D. C. A 28 page planographed monthly news summary: the social security program for children; maternal, infant, and child health; child labor; socially handicapped children; international and foreign notes. A helpful device is the sub-title, "Book and Periodical Notes," under most of the main headings. *Free.*

Health Education in July, 1936, Journal—Having more or less to do with health education are the references noted below.

The quotation about Charles Kingsley (page 671) may be usable on occasion.

"Effect of Relief Programs on Public Health Nursing in the State, by MacDougall (pages 672–676), discusses *preparation of the nurses*, and certain community relationships.

"The Sanitary Code" (page 676): early history of English public health organization.

A plea for accurate use of the word "cure" (page 724).

Especially interesting and significant is the announcement, "Office of Public Health Education Established" (page 732), in the U. S. Public Health Service.

See "The Art of Leadership" (page 743) in "Books and Reports."

Hygeia, August, 1936—Titles and topics for various uses are suggested by the contents of *Hygeia*, 535 N. Dearborn St., Chicago, Ill. A copy *free* to teacher or health worker.

The other side of motor casualties (not due to the driver). . . . The care of infantile paralysis. . . . The "compatible eating" fad. . . . Health and the circus (the hospital car and medical services). . . . Home canning for the diabetic. . . . Safety in industry. . . . The Martin family vacation; eagle scout; little sister; garbage; camp fires; let's eat, but where? . . . Ignaz Philip Semmelwers (Hungarian). . . . Impending mosquito massacres (wholesale methods). . . . Mental attitudes vs. health. . . . And the deaf shall speak (lip reading). . . . Evolution of the microscope (picture page). . . . Germs and their enemies.

RADIO

A "Station List" is supplied free by Radio Institute of the Audible Arts, 420 Lexington Ave., New York, N. Y. Lists stations of major networks, giving city, network, and frequency. Will aid in locating health talks given outside your city.

An Early Diagnosis Campaign broadcasting program in April was conducted by New York Tuberculosis and Health Assn. in coöperation with National Tuberculosis Assn. and New York Academy of Medicine. There were 30 talks over 11 stations with 8 talks on networks of Columbia, National, Mutual or Knickerbocker systems.

American Medical Assn. (N.B.C. Red network and Pacific network):

Little tips on home hygiene . . . Heart disease . . . Crippled children . . . Cancer . . . Hard of hearing . . . Eyesight saving . . . Hay fever and asthma . . . Let your doctor decide . . . Middle age . . . Summer camps.

Baltimore Health Dept. and Medical and Chirurgical Faculty of Maryland:

Care of baby during the winter . . . Meningitis on the increase . . . Another public health enemy: lobar pneumonia . . . Baby's bath . . . Banish ancient food fallacies . . . Rats: our million dollar luxury . . . This is Negro health week . . . Summertime and typhoid fever.

Connecticut State Dept. of Health (WTIC):

Standards for clean milk . . . The child is father to the man (mental hygiene) . . . In the wake of the venereal diseases . . . Dying 200 different ways . . . Modernization of water supplies . . . Public health nurse a good investment . . . How about breakfast? . . . Your cook: friend or foe . . . Cost of venereal disease . . . Value of records . . . Public and private nuisances.

Illinois State Dept. of Public Health (WHFC or WGN):

Is this the most interesting subject to Americans? (stomach) . . . Public enemies (syphilis) . . . Can we be cancer wise and cancer sensible? . . . Speaking of kidney disease . . . The great American deterrent (failure of prisons) . . . Morons, medicine, and mental hygiene . . . The new commanding general and the health army (Dr. Parran) . . . Public health and public enemies . . . Control of crime . . . Pure cosmetics and the skin game . . . Food, mothers, and the law.

Jefferson County Board of Health (Birmingham, Ala.) (WAPI):

School children and communicable diseases . . . "That bad cold" . . . The process of growing old . . . The greatest world war of all time (germs) . . . Influenza . . . Good manners and the public health.

Minnesota State Medical Assn. (WCCO):

Hay fever . . . Rheumatic fever . . . Narcolepsy . . . Sore mouth.

New York City Dept. of Health:

Posture and people . . . In the headlines (cancer) . . . Health on review . . . Your child a movie actor? (improving the child's face) . . . Anemia . . . "I can't understand what's come over her" (an interview) . . . Your city's health . . . Milk and the seven ages of man . . . They bring health to the people (public health nurses) . . . Emancipation from disease . . . High blood pressure . . . Sense, safety, and reducing (a series) . . . Common sense and mental hygiene . . . The ads in heaven.

Ohio State Dept. of Health (WOSU):

Tuberculosis sanatorium education . . . Trichinosis . . . Crippled child . . . Explanation of the tuberculin test . . . The winter's carbon-monoxide record . . . Importance of dental care . . . Seasonal hazards of typhoid fever . . . Stream polution abatement . . . Summer problems in milk sanitation.

IT HAS BEEN DONE

A fact made graphic:

The National Organization for Public Health Nursing staff, in visiting 44 states, has traveled 4.7 times around the world.

The 6th annual health poster contest for high school art students in New York has just ended. The contest is distinctive in (1) the coöperation of education and health authorities; (2) the active participation of the outdoor advertising industry; (3) the nature of the awards; (4) and the actual billboard production of the prize winning poster, usually. For the contest folder write to Committee on Tuberculosis and Public Health, S.C.A.A., 105 E. 22d St., New York, N. Y.

FOR USE OR REFERENCE

For background, to pass on to selected people, to reproduce, to adapt—here are a variety of items to select from.

Many publications formerly issued by the American Child Health Assn. are now supplied by either the American Public Health Assn., 50 W. 50th St., New York, N. Y., or National Education Assn., 1201 16th St., N.W., Washington, D. C.

A series of mimeographed pamphlets has been prepared by New York Diabetes Assn., a subsidiary of New York Tuberculosis and Health Assn., 386 4th Ave., New York, N. Y. Each is mimeographed on letter size sheets, with a stiff, colored cover. The cover page is lettered with the stencil device provided for use with the mimeograph. With a back cover sheet, and three staples on the left, the series is given physical weight and permanence for continued office use. The titles:

Survey of Diabetes Clinics in New York City

Diabetics Under Treatment in New York City

Incidence of Diabetes in Certain Educational and Industrial Groups

Directory of Diabetes or Metabolism Clinics in New York City

The New York Diabetes Association

If you have any building or institution with a bit of planting space for

trees or shrubs see " Getting Material to Beautify the Plant," by C. K. Calvert. *Municipal Sanitation*, 24 W. 40th St., New York, N. Y. April, 1936. *15 cents*. An appeal for planting; what to plant, and how.

" Advancing the Health and Welfare of the Nation's Children Through Federal and State Coöperation," by K. F. Lenroot. Reprint. U. S. Children's Bureau, Washington, D. C.

" Delinquent Patients in Venereal Disease Clinics," by Reinhard and Fales. Reprint. Health Dept., Baltimore, Md.

" Foods and Cooking," etc. List of government publications for sale. Supt. of Documents, Washington, D. C. *Free*.

" General Anesthesia: Historical High Lights," by J. T. Gwathmey. Reprint. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. *5 cents*.

" A Manual of Information for Physicians on the Treatment of Syphilis and the Control of Venereal Disease," by Stokes, Parran, and others. Reprint. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. 48 pages. *10 cents*.

" Medicine and Men," by F. E. Sondern, M.D. 8 page reprint on medical economics. Public Relations Bureau, Medical Society of State of New York, 2 E. 103 St., New York, N. Y. *Free*.

" The Menace of Trench Mouth," by J. A. Tobey. Reprint from *Good Housekeeping*. *Free* from the author, 350 Madison Ave., New York, N. Y.

" The Pasteurs, Kochs and Listers of Today " is a series of brief biographies with drawings of " living health heroes ": Dr. Mary Rose, Dr. Sherman, Dr. Crile, Dr. Park, and others. Health News Service, 22 E. 40th St., New York, N. Y. Prepared for newspaper publications, the material should be useful in health agency house organs, employees' house organs, foreign language papers (which include some English), etc. Mats are available for the articles, and for the headings and drawings.

" Pneumonia." Definition; method of spread; prevention; care of a patient; serum treatment. 4 page folded; uncrowded pages. New York State Dept. of Health, Albany.

" The Problem of Fireworks Accidents." Various authors. National Society for Prevention of Blindness, 50 W. 50th St., New York, N. Y. 30 pp. *15 cents*. Accompanied by chart reporting details of accidents, state by state.

" Protecting the Dionnes " is a 24 page advertising pamphlet, with some 24 pictures of the famous babies, with text. Lehn and Fink Products Corporation, Bloomfield, N. J.

" Public Health Service Publications." List of issues July–Dec., 1935. *Public Health Reports*, Supt. of Documents, Washington, D. C. April 17, 1936. *5 cents*. Most of the technical pamphlets listed are supplied *free*.

" Silicosis: An Interpretive Review of Accumulated Experience," by Dr. C. O. Sappington. Revised in 1934 it is again timely. Address the author, 330 S. Wells St., Chicago, Ill.

" Sissy," by Florence M. Bauer. A play. Reprint from *Hygeia*. American Medical Assn., 535 N. Dearbrn St., Chicago, Ill. *10 cents*.

" Wage Your Fly War Coöperatively," by R. W. Harvey. *Eastern States Cooperator*, 95 Elm St., West Springfield, Mass. June, 1936. *Free*. Information to pass on, especially in rural work.

" What Every Teacher Should Know About the Physical Condition of Her Pupils " (30 pp.); " Training of Elementary Teachers for School Health Work " (27 pp.). Both by J. F. Rogers, U. S. Office of Education. Supt. of Documents, Washington, D. C. Each *5 cents*.

BOOKS AND REPORTS

Public Health Nursing—*By Mary Sewall Gardner, R.N. (3d ed.) New York: Macmillan,* 1936. 476 pp. Price, $3.00.

Miss Gardner's book, *Public Health Nursing,* has ever since its first edition in 1916 been the only text of its kind in the field. This new edition, the third, lives up to the high standards set by its predecessors and will prove of value to all who are interested in the public health nursing movement. No nurse can read the first few chapters, which deal with the historical development of public health nursing in this country and abroad, without being thrilled at the picture she draws of similarity of purpose and principle, and of wide variation of method due to local conditions. Practice in this country is then discussed in detail, emphasizing always the underlying principles, and considering those problems which arise in relation to the nurse herself—her selection and preparation, her relations to families, other health and social workers, and to the supporting public. What does public health nursing have to offer? What does it demand of the staff nurse, the supervisor, the administrator? Here Miss Gardner's years of professional experience and her personal wisdom stand her in good stead, and she writes with an understanding and insight that make these chapters well worth the reading.

The latter part of the book is devoted to the larger problems of organization and administration, support under private and public auspices, the value of lay boards, and use of volunteers. Those special services in which the public health nurse plays an important part are discussed in some detail—the maternity and child health program, school and industrial nursing, the control of communicable diseases, mental hygiene, and the contribution of the public health nurse to this movement.

With the rapid expansion of public health nursing today, especially in the rural areas, there is need on the part of all for clear thinking and an appreciation of basic principles if growth is to be sound. Miss Gardner's book makes us mindful of the fine achievements of the past, and points the way to sound developments for the future. It is worthy of careful study by all who would practise the "art" of public health nursing.

KATHARINE FAVILLE

Vitality: A Book on Health for Women and Children—*By Elizabeth Sloan Chesser, M.D. New York: Oxford University Press,* 1935. 254 pp. Price, $2.50.

A good many medical authors in writing books for the general public seem to have considerable difficulty in working out a consistent plan. Usually the error committed is one of including too much medical detail. This is true of the book under review. Much of Section 2 comprising the last 145 pages and dealing with sick nursing in the home could have been omitted with advantage. After all, it is the attending physician who is responsible for the care of the ill and it does not help much to have someone else tell the nurse, whether through the pages of a book or otherwise, that the family physician will probably do this or will probably order that. On the other hand this book fails to grasp a real opportunity to emphasize again and

again the importance of such preventive measures as immunization.

The first section of the book dealing with ways of keeping healthy is better. Even here, though, the statements are often exaggerated or inaccurate; as, for example, "When we are healthy and fit we do not succumb to the microbes of disease, even when we breathe or swallow them." The chapters on Health and Education; The Healthy Child; and Youth and Health are pretty good, although a touch of Polyanna spoils some of the advice on mental hygiene. After all, seeing and facing things as they are without self-hypnosis is not so bad a rule to follow whereas "Thinking the Right Thoughts"—with capital letters, of course—may not infrequently degenerate into piffle.

On the whole, the reviewer thinks that there are more useful books than this available to the public.

MERRILL E. CHAMPION

Hospital Accounting and Statistics: A Manual for American Hospitals—*By Michael M. Davis et al. Chicago, Ill.: American Hospital Association,* 1935. 85 pp. Price, $1.00.

Accurate and relatively complete data regarding the costs of medical care are, perhaps, more urgently needed by those truly interested in the broader aspects of medical service than any other single type of data. And, although estimates of the cost of hospital care are probably more reliable than estimates of other varieties of medical service, there is still opportunity for tremendous improvement. Especially is it true that there is much to be desired in the unification of hospital statistical reports.

The present book contains an outline of standard procedures for the handling of hospital expense and income accounts. The primary aim of the book is to present methods of classification that can be used by hospitals throughout the country. Clear-cut definitions and sufficient details are given to permit the adoption of the plan in all hospitals whether large or small, public or private. The next step, which is undoubtedly more difficult, involves the development of a plan for insuring its general adoption. The American Hospital Association and its Council on Community Relations and Administrative Practice are to be congratulated for the completion of the initial step in this pioneer work.

CARROLL E. PALMER

Swimming Pool Data & Reference Annual—Volume IV—*Earl K. Collins, Editor. New York: Hoffman, Harris, Inc.,* 1936. Price, $2.00.

The 1936 *Swimming Pool Data and Reference Annual,* which is the fourth volume of this book, brings together in a comprehensive reference manual selected articles written by some outstanding authorities in the swimming pool field. The book is instructive and well worth reading by all interested in swimming pools in any way, but is of special interest to architects and engineers; to contractors; to swimming pool owners and operators; to swimming instructors; and to public health officials.

The 1935 Report in full by the Joint Bathing Place Committee of the State Sanitary Engineers and the American Public Health Association is included. This report should be in the library of all public health officials interested in the supervision of swimming pools. A very timely article on wading pools by Dr. W. J. McCormick stresses the point that if a wading pool is deep enough to allow swimming by the children it should be designed as a swimming pool, but that if a pool is to be used as a wading pool, and is so designed, the use of the pool should be rigidly restricted to wading only. The tendency in some cities is to build swimming pools for

children, but call them wading pools. Dr. McCormick also shows that there is practically no supervision of wading pools throughout the United States.

The answers to an interesting questionnaire have been compiled by Editor Earl K. Collins on charges, fees, practices of swimming pools on a national basis, after a nation-wide survey of swimming pools.

There is a special worth while article to the public health officials and to the operators of swimming pools written by C. A. Holmquist and Charles R. Cox of the New York State Health Department on the "Guidance in the Design and Operation of Municipal Pools." This article should be read by all those responsible for the development of park systems in municipalities.

Special types of the most modern pools are described. The construction of water-tight pools is also outlined in a separate article. Among the helpful practical discussions is one on the swimming pool operators' problems which outlines the results of a nation-wide survey. E. S. Bishop discusses water temperature control for shallow baths and pools. A mechanical engineer compares the cost of purchased versus privately pumped water and also the piping hook-up for utilizing steam in a pool. The manager of a hotel pool outlines some important points in the cleaning of pools with the suction cleaners. A representative of the tile manufacturers association discusses tile and tile work for swimming pools.

A large number of commercial companies advertise equipment and supplies for swimming pools covering pretty well the entire field.

Anyone interested in swimming pools, whether designing, constructing, or operating a pool, supervising the operation of swimming pools from the public health viewpoint, or interested in swimming and in physical education progress, will find it well worth while to have a copy of this reference in his library. ALFRED H. FLETCHER

Sports for Recreation and How to Play Them—*The Staff of the Intramural Sports Department, University of Michigan, Elmer D. Mitchell, Editor. New York: Barnes,* 1936. 467 pp. Price, $2.50.

This text covers 28 sports, ranging from archery and horseshoe pitching to ice hockey and touch football, including such typical sports as boxing and wrestling, swimming, rowing, fencing, and soccer.

Designed "to extend and develop the increasing interest in healthful recreations, to assemble in convenient form needed information on the various forms of physical recreation . . . and to treat each sport from the standpoint of the beginner or average player . . ." it meets a real need.

Considerably more than half the content is devoted to individualistic competitions, such as tennis, golf, swimming, fencing, winter sports, and the like, which have a distinct value as recreation in years after college, when playing team games is less attractive and not safe. This is in accord with the modern trend in physical education which aims at training for a lifetime, rather than for the exhibitionism of football, basketball, and other team games. CHARLES H. KEENE

Current Problems in Camp Leadership—*Edited by J. R. Sharman, Marjorie Hillas, and D. K. Brace. Ann Arbor: Ann Arbor Press,* 1934. 120 pp. Price, $1.25.

This workbook for camp counselors and directors is the product of an editorial board, the members of which are engaged in physical education, camp work, or recreation activities in various parts of the country. Stimulation of the camping movement created a demand for leaders in camps. At the

time of printing, over thirty institutions were conducting courses for the professional preparation of camp counselors and directors. The volume was designed to meet the need for organized materials suitable for use in such college courses, coupled with a need for materials for use in the pre-camp training periods conducted by camps for the preparation of counselors. The preface states: "The ideal camp director or counselor should be a person of superior personality with a broad education and several years of successful experience in camping."

The contents are divided into 34 units, each prepared by contributors especially selected because of experience in the field discussed. These units deal with: duties of personnel, camp organization, camp objectives and government, health education, personal health problems, mental hygiene, first aid, education, sports and other activities, art, handicraft, music, sanitation, methods of appraising results and of measuring the effects of camp life. Each unit consists of introductory paragraphs leading up to a series of exercises and problems for the student, followed by useful references.

To quote from the unit on health education:

> Living in the out-of-doors under proper conditions is generally considered healthful, yet boys and girls have returned from camp tired, restless, and weighing less than when they went to camp. In recent studies, it has been attempted to determine the extent to which camp life contributes to healthful development of the campers. Implications from these studies are that the camp contributes to healthful development only in the proportion to which it is organized and administered according to progressive health practices. An effective and efficient health program should include (1) health supervisory activities, (2) health service activities, and (3) health instruction activities.

And later under personal health problems:

> Although the health of the camper is the chief concern of the camp physician, the nurse, and the dietitian, nevertheless the general staff, including the director and all counselors, has no small part to play in the health program.

In the next edition, the importance of additional public health safeguards, such as pasteurized milk, might be stressed, but in general this book represents a useful contribution of much value to those concerned with the camping problem, including public health officials. IRA V. HISCOCK

California Medical Association Cancer Commission Committee Studies—*San Francisco: J. W. Stacey, Inc.*, 1936. Paper, 129 pp.

One of the greatest obstacles to the cure of cancer is the fact that its early diagnosis and proper treatment lie often beyond the ability of the physicians who first see the cases. Another is the fact that suspicious cases are not more often referred, during the period when they are curable, to physicians who have the knowledge and skill to handle them in accordance with advanced practice. Cancer is a condition which generally calls for very special attention, and the average practitioner of medicine or surgery is not necessarily possessed of the training and experience in this particular direction to qualify as an expert.

The publication under review is an attempt to reduce the gap between the best knowledge and the common knowledge of cancer in its various forms and locations. It is chiefly the work of a permanent committee, or so-called Cancer Commission, appointed by the California Medical Association in 1931, and of a number of committees appointed by that commission. During the last 5 years a series of articles by these committees have been published by the Cancer Commission in *California and Western Medicine*, and these have now been brought together and published in the little volume before us. The

publication is for medical men entirely.

There are sections on tumors in various parts of the body and one on the subject of radiology. Each section is signed by a dozen or more physicians who are immediately responsible for it; the one on radiology has thirty-eight individual sponsors. This gives to the pronouncements an appearance of authority and disarms any criticism that anybody is advertising—two considerations to which physicians who do considerable work with cancer patients feel compelled to give much attention.

The book is compact, and well divided and sub-divided for rapid reference, but its very small type and poor paper, together with its paper cover and pocket size, make it less comfortable to read and less likely to be found when wanted than could be desired. Its newness gives it a special value. Thought and practice have been advancing considerably in the diagnosis and treatment of cancer and every physician and surgeon should strive to keep abreast of this progress, at least in his reading. GEORGE A. SOPER

A Survey of Public Health Activities in Honolulu, Hawaii—Including Official and Voluntary Agencies—*By Ira V. Hiscock, C.P.H. Chamber of Commerce of Honolulu,* 1936. 149 pp.

This book should be read by all engaged in public health administration if for no other reason than to give them a cause to ponder over the shortcomings of health work in the continental United States. The tremendous possibilities for good in the loyal and intelligent support of official health administration by civic organizations is evidenced from beginning to end in this report.

Public health administration in the Island territory was surveyed in 1928, and the far reaching recommendations of that report were carried out to a surprising degree during the years intervening between it and the survey reported upon (conducted, be it noted, by this Chamber of Commerce). Though known as "the paradise of the Pacific," the Islands suffer the imperfections of this mundane sphere, so further improvements in public health administration naturally were discovered.

The recommendations are so eminently practical, and the need for betterment in public health administration so pressing that one feels sure that a subsequent survey will find them as nearly completely met as were those of the first. That the Island territory will have an administrative organization of unusual efficiency is safe to prophesy when one considers the agencies and people behind the movement. The author says in his introduction: "To have the opportunity to return to Honolulu was a special pleasure." A reading of the report leaves no doubt of the sincerity of that comment.

RAYMOND S. PATTERSON

Manson's Tropical Diseases—*Edited by Philip H. Manson-Bahr (10th ed.) Baltimore: Wood,* 1936. 1003 pp. Price, $11.00.

This treatise, which has been for so long a standard, has now reached its 10th edition. The most notable change in the new edition is the expansion of the text on the clinical side, which has necessitated cutting out some of the scientific matter concerning medical zoölogy. The editor explains this by his desire to follow the design of the author to make this manual a practical volume for those practising medicine in the tropics.

The text is clear and readable. It is illustrated by 22 color and 15 half-tone plates, 381 figures, 6 maps, and 38 charts, all of which are excellent. It is a book which belongs on the shelf of everyone who is interested in tropical diseases. MAZŸCK P. RAVENEL

The Sanitary Inspector's Handbook: A Manual for Sanitary Inspectors and Other Executive Public Health Officers—*By Henry H. Clay. (2d ed.) London: H. K. Lewis & Co., Ltd.*, 1936. 432 pp. Price, $4.75.

The work of the sanitary inspector has been developed to a higher point in England than in any other country. It has, in fact, been so far advanced that one might almost regard this calling as a profession. Like other professions, it has its specialists.

Courses of instruction are given at various approved places; and such subjects as physiology and hygiene, elementary physics and chemistry, and the technology of buildings are covered in the courses. A specified period of time must be spent in a public health department. Finally, an examination is given by the Royal Sanitary Institute and Sanitary Inspectors Examination Joint Board, those passing being given a certificate which is everywhere required by law in England and Wales for persons who are to be appointed inspectors.

The book is divided into 31 chapters and there are 95 illustrations. Among the chapters of particular interest to Americans are those which are devoted to nuisances, offensive trades, housing, lighting, water, smoke, drainage, plumbing, sewage and sewage disposal, refuse disposal, ventilation and heating, factories and workshops, dairies and slaughter-houses, protection and preservation of food, infection and disinfection, and vital statistics.

The attitude held in England as to the relation of nuisances to disease is described. The earliest laws for the abatement of nuisances were based simply on the discomfort which they produced rather than any idea of their relation to health. Later, the idea that epidemic disease was perhaps due entirely to the harmful effects of nuisances came to be generally held. Today nuisances are dealt with:

> . . . not because they, in fact, cause specific disease, but in order to afford and secure to the people fuller physical enjoyment of life: that by the removal of nuisances their surroundings may be made more pleasant, and because a healthy environment must obviously react favorably upon individual and public health.

Although the book explains much about the law of England and Wales and is not intended so much for American as for British use, there is a great deal that sanitarians will find applicable to conditions in the United States. It is today the best book of reference on the subject with which it deals.

The book is carefully written and by an authority, who is a Fellow of the Royal Sanitary Institute and Lecturer in Sanitary Engineering, London School of Hygiene and Tropical Medicine, University of London. The original edition was brought out in 1933 and replaced the well known volume on the same subject by Taylor, revised by Clarke, both of whom are now dead.

GEORGE A. SOPER

The Balanced Diet—*By Logan Clendening, M.D. New York: Appleton-Century*, 1936. 207 pp. Price, $1.50.

This little book of 207 pages presents in concise yet very readable form the fundamentals of nutrition. The author's breezy style holds one's interest from page to page and from chapter to chapter. This is a book for the layman who wishes to obtain without too much mental effort a knowledge of foods, diets, and their relation to human health. Of course in a semi-popular presentation of this sort it is necessary to make many generalities. This is the case in *The Balanced Diet*. Some of these generalizations are not fully true or proven and sometimes there are unmentioned exceptions to the stated rule. There are many quotations

from other writers to illustrate various viewpoints.

The chapter on food fads is one of the best. In this the author covers well such topics as fasting, aluminum scare, food acidity, and vegetarianism. The final chapter on The Economics of Food is so tersely dealt with that it might as well have been omitted. A set of food tables omitting minerals and vitamins is appended.

CARL R. FELLERS

Die Methoden der Wohnungshygiene—*By Karl Süpfle and Paul Hoffmann. In Abderhalden, Handbuch der biologischen Arbeitsmethoden,* Abth. IV, Teil 11, Heft 4, Leif. 431, pp. 559–770, 75 figs. in text, 1934. Price, R.M. 10.

This is a comprehensive treatise on the hygiene of the home or dwelling. It deals with the scientific methods of examination of the site; determination of air and water in the soil, its permeability, chemical constitution, bacterial content, temperature, level of ground water; building materials, with reference to their permeability by air and water, moisture capacity of mortar, deadening of sound, insulation against temperature changes and loss of heat, strength of materials, and protection against attack of wood-destroying fungi.

The problem of heating is discussed from the standpoint of determination of requirements, testing of installations, and calculation of dimensions of gas piping for stoves and heating equipment.

Ventilation requirements are computed on the basis of the production of CO_2, heat, and moisture by the occupants according to age. Air pressure is computed with reference to normal changes in temperature, and elaborate formulae are given for the measurements of the movement and rate of change in the air. Special attention is given to temperature, measurement and control of humidity and carbon dioxide content, and the the detection and measurement of the deadly carbon monoxide. Methods of testing for the amount of dust entering the home are described.

The problems of lighting are treated quantitatively from the standpoint of methods of determining the quantity and intensity, angles of dispersion, requirements in dimensions of windows, angles of panes, and optical qualities of various kinds of glass.

AN AMERICAN DOCTOR'S ODYSSEY. By Victor Heiser, M.D. New York: Norton, 1936. 544 pp. Price, $3.50.

CASH RELIEF. By Joanna C. Colcord. New York: Russell Sage Foundation, 1936. 263 pp. Price, $1.50.

DISINFECTION AND STERILIZATION. By Ernest C. McCulloch, M.A., D.V.M., Ph.D. Philadelphia: Lea & Febiger, 1936. 525 pp., ill. with 53 engravings. Price, $5.50.

GYNECOLOGY AND OBSTETRICS. By Edwin Jameson, M.D. Vol. XVII, Clio Medica Series, edited by E. B. Krumbhaar. New York: Hoeber (Medical Book Department of Harper), 1936. 170 pp. Price, $2.00.

INTERIM REPORT TO THE NATIONAL RESOURCES COMMITTEE. By the Research Committee on Urban Problems, Clarence A. Dykstra, Chairman. Washington, July, 1936. 188 pp.

PHYSICIAN, PASTOR AND PATIENT: PROBLEMS IN PASTORAL MEDICINE. By George W. Jacoby, M.D. New York: Hoeber (Harper), 1936. 390 pp., ill. Price, $3.50.

PREVENTIVE MEDICINE (5th ed.). By Mark F. Boyd, M.D. Philadelphia: Saunders, 1936. 561 pp., ill. Price, $4.50.

THE PSYCHOLOGY OF ADOLESCENCE. By Luella Cole, Ph.D. New York: Farrar & Rinehart, 1936. 503 pp. Price, $3.50.

PUBLIC ADMINISTRATION. By John M. Pfiffner, Ph.D. New York: Ronald, 1935. 525 pp. Price, $4.00.

WATER PURIFICATION CONTROL (2d ed.). By Edward S. Hopkins. Baltimore: Williams & Wilkins, 1936. 184 pp. Price, $1.75.

YOUR HAY FEVER. By Oren C. Durham. With an Introduction by Morris Fishbein, M.D., and a Chapter on Treatment by Samuel M. Feinberg, M.D. New York: Bobbs-Merrill, 1936. 264 pp. Price, $2.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Tuberculosis Case Finding—Most tuberculous people are unaware of their infection, and the condition will not be diagnosed until the disease is far advanced. The most effective way of discovering early infections is by chest surveys of susceptible groups. If properly treated, the spread of the disease is prevented.

AMBERSON, J. B. Case Finding Methods for the Diagnosis of Tuberculosis. J.A.M.A. 107, 4:256 (July 25), 1936.

More about Tuberculosis Case Finding—Arguments are advanced for testing school children for tuberculosis and for the examination of adults in the homes of child reactors. Educational values in routine testing are emphasized.

BROWN, W. P. Economy in Tuberculosis Case Finding Through the Schools. Pub. Health Nurs. 28, 7:455 July), 1936.

Adequate Nutrition and Pregnancy—This discussion of maternity benefits and their effect upon the health of mothers and infants in Europe will make strange reading for us in this country.

BALFOUR, M. I. Nutrition as a Factor in Pregnancy and Childbirth. J. State Med. 44, 7:391 (July), 1936.

Mosquito Control on a Grand Scale—With 2,300 miles of reservoir shore line the extent of the malaria control problem in the Tennessee Valley is evident. From the extensive organization formed to attack the problem one may predict an effective program.

BISHOP, E. L. Malaria Control Activities of the Tennessee Valley Authority. Pub. Health Rep. 51, 29:970 (July 17), 1936.

Composite Ranking of Diseases and Defects—Looking beyond the ordinary mortality and morbidity tables an attempt is made to estimate the true position of the various diseases. The outstanding diseases are grouped: (1) influenza and pneumonia, tuberculosis, heart disease; (2) cancer, rheumatism, dementia precox; (3) syphilis, appendicitis, mental defect, results of childbirth. A stimulating study.

BRITTEN, R. N. Important Causes of Sickness and Death. Pub. Health Rep. 51, 29:947 (July 17), 1936.

Saving New-Born Babies—Steady declines in the neonatal and infant death rates in Chicago during the last 10 years indicate that measures found effective in hospital practice may be applied successfully to city-wide conditions. Prematurity is a great factor in infant deaths, and lack of antepartum and postnatal care influences deaths among premature babies. The infant hygiene program of the Chicago Health Department is described.

BUNDESEN, H. N., *et al.* Mortality of New-Born Infants in Chicago During 1935. J.A.M.A. 107, 4:270 (July 25), 1936.

Preventing Typhoid Fever — In general, typhoid prophylaxis is resorted to most frequently in those parts of the country with the greatest typhoid fever problem. Seasonal peaks of immunizations occur about 2 months before the peak of cases in anticipation of, rather than in the face of, epidemics.

COLLINS, S. D. History and Frequency of Typhoid Fever Immunizations and Cases in 9,000 Families. Pub. Health Rep. 51, 28:897 (July 10), 1936.

Marriage and Mental Health—Among persons admitted to mental hospitals, the rate was lowest for married people and, in order, higher for single people, widowed, and divorced. In the last group the rate was 4 times that of the married.

DAYTON, N. A. Marriage and Mental Disease. New Eng. J. Med. 215, 4:153 (July 23), 1936.

How Long Shall Unnecessary Maternal Deaths Continue?—Maternal death rates remaining high despite studies, surveys, reports, and resolutions, the demand is made that adequate prenatal services be effectively coördinated with decent lying-in and postpartum services. A definite program is outlined.

DUBLIN, L. I., and EMERSON, H. Maternal Mortality (A Symposium). New York State J. Med. 36, 13:1002 (July 1), 1936.

Fortified Milks—As prophylactics against rickets, both yeast-fed and irradiated vitamin D milk were found adequate. That higher vitamin D content was of additional value as a prophylactic was not established.

ELEY, R. C., *et al.* The Prophylactic Value of Vitamin D Irradiated and Vitamin D Yeast-Fed Milk. New Eng. J. Med. 215, 3:110 (July 16), 1936.

Unpleasant Thought-of-the-Month—Lymph nodes in 4 of 88 swine carcasses "passed for food" contained viable avian tuberculosis bacilli. The study is a reminder that virulent tubercle bacilli may be present in pork even though visible lesions of tuberculosis have been removed.

FELDMAN, W. H. The Recovery of Virulent Tubercle Bacilli from the Tissues of Swine Intended for Food. J. Infect. Dis. 59, 1:42 (July-Aug.), 1936.

Hospital Plumbing—Traced to a carrier in a hospital diet kitchen this unusual epidemic of paratyphoid fever mixed with other enteric organisms seems to have been spread largely through water contaminated with sewage.

FOLEY, A. R., and FAILLE, J. L. A Hospital Epidemic of Paratyphoid A. Canad. Pub. Health J. 27, 7:313 (July), 1936.

Viewers-with-Alarm Please Note—In Stockholm educated married couples have more children than do those in "lower" social strata.

HUTCHINSON, E. P. Education and Intramarital Fertility in Stockholm. Milbank Quart. Bull. 14, 3:285 (July), 1936.

European Experience with BCG—The vaccine is harmless and is of some value if used as an adjunct to other prophylactic measures. The author concludes that Calmette would serve the cause of immunization better had he remembered what Renan once said to an over-enthusiastic Pasteur: "Truth is a great coquette; she will not be sought with too much passion, but is often most amenable to indifference. She escapes when apparently caught, but gives herself up if patiently waited for."

KAYNE, G. G. BCG in Western Europe. Am. Rev. Tuberc. 34, 1:10 (July), 1936.

Are Colds Infectious?—Arguments are presented in defense of the postulate that the true common cold is not a communicable disease but a condition of faulty accommodation to unfavorable environment.

KERR, W. J. The Common Cold. J.A.M.A. 107, 5:323 (Aug. 1), 1936.

Treating Colds—Glib advice about taking your cold to bed, so dear to the heart of the health educator, was put to the test. Within the limitations of the study it was found that illness was shortened and complications were prevented when victims went immediately to bed as compared with those who waited 5 days before doing so.

LEBLANC, T. J., and WELBORN, M. B. The Common Cold and the Effect of Rest in Bed on Its Course. Am J. Hyg. 24, 1:10 (July), 1936.

Dependency and Physical Defects —One-fifth of all persons over 16 on relief rôles had serious physical handicaps. Evidence is presented that physical impairment is an important cause of dependency. Disabilities were 3 times as common in families on relief as among non-relief persons.

PERROTT, G. ST. J., and GRIFFIN, H. C. An Inventory of the Serious Disabilities of the Urban Relief Population. Milbank Quart. Bull. 14, 3:213 (July), 1936.

Occupational Therapy for Convalescents—In the industrial clinic at Leysin, Switzerland, work benches and motors have been installed near the beds in tuberculosis wards, so that bed patients have available miniature factories, while in the convalescent workshops much more complete equipment is provided. Work is adapted to the physical condition of each patient, and the psychological therapeutic effect is excellent.

ROLLIER, A. The Industrial Clinic at Leysin. Internat. Nurs. Rev. 10, 2:142, 1936.

Next Steps in Public Health—This memorandum, the last paper written by Edgar Sydenstricker, intended to serve as the basis for what is one of the outstanding meetings in the whole field of public health, is in reality a document of rare importance. The discussions that follow, contributions of the leaders in public hygiene, fully meet the promise of the introductory memorandum.

SYDENSTRICKER, E., *et al.* The Next Steps in Public Health. Proceedings of the Fourteenth Annual Conference of the Milbank Memorial Fund. Mar. 26, 1936.

Can Public Opinion Affect Maternal Deaths?—Let the blame for high British maternal mortality go where it belongs, concludes this writer: to a careless public, an inefficient midwife, an inept doctor, or a badly-run health department.

TOPPING, A. Maternal Mortality and Public Opinion. Pub. Health 49, 10:342 (July), 1936.

Influencing John Public's Behavior—What the municipal health department can and should do to stimulate popular support for its projects and public interest in personal health is briefly and convincingly set forth by one who knows from his own experience. First is individual contact, then group instruction, finally, general and supplementary information and publicity.

ZIMAND, S. The Educational Work of a Health Department. Pub. Health Nurs. 28, 7:446 (July), 1936.

ASSOCIATION NEWS

AMERICAN PUBLIC HEALTH ASSOCIATION
SIXTY-FIFTH ANNUAL MEETING
NEW ORLEANS, LA.

OCTOBER 20-23, 1936

For Preliminary Program, Railroad Fares, and Hotel Rates, see Supplement in back of Journal

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Richard M. Adams, M.D., State Health Department, Oklahoma City, Okla., State Director of County Health Units
Daniel C. Barrett, M.D., C.P.H., 3318 Browning Ave., Cincinnati, O., District Physician, City Health Department
John H. Cauley, M.D., 33 Adams St., Dorchester, Mass., Medical Inspector, Boston Health Dept.
Chadwick W. Christine, M.D., Flemingsburg, Ky., Fleming County Health Officer
James S. Cull, M.D., D.P.H., Pouce Coupe, B. C., Canada, Director, Peace River Health Unit
James O. Foster, M.D., Luverne, Ala., County Health Officer, Crenshaw County Medical Board
Max C. Igloe, M.D., Big Rapids, Mich., Director, Mecosta-Osceola Health Dept.
Lester C. Krotcher, M.D., Twin Falls, Idaho, Director, Twin Falls Health Unit
Leo M. Morse, M.D., C.P.H., First National Bank, Neillsville, Wis., District Health Officer, State Board of Health
Edward W. Palmer, Great Plain Ave., Needham, Mass., Acting Health Officer
Arthur O. Peters, M.D., 15 N. 4th St., Dayton, O., Commissioner of Health

Laboratory Section

Elizabeth L. Hazen, Ph.D., 440 Riverside Drive, New York, N. Y., Senior Bacteriologist, Division of Laboratories and Research, State Dept. of Health
Katherine H. Kramer, 136 Elder Ave., Lansdowne, Pa., Laboratory Technician
Meyer Samson, 1619 Spruce St., Philadelphia, Pa., Director, Samson Laboratories
Edna L. Smith, State Board of Health Laboratories, Jefferson City, Mo., Bacteriologist

Vital Statistics Section

Madge Proctor, 527 E. High, Jefferson City, Mo., Statistician, State Board of Health

Public Health Engineering Section

Herbert M. Bosch, District Health Unit No. 2, Mankato, Minn., District Public Health Engineer
Eldridge N. Brown, D.V.M., 1701 Sevier St., Nashville, Tenn., Veterinarian and Dairy Inspector
Michael E. Doyle, Box 424, Albany, Ga., District Sanitary Engineer, State Board of Health
Charles H. Field, Albany, Ga., Sanitary Engineer, Dougherty County Board of Health
Leon E. Johns, 218 S. West Fifth Ave., Ft. Lauderdale, Fla., Sanitary Officer, Broward County Health Dept.
Harold L. Malone, Coöperative Health Unit District No. 1, Tahlequah, Okla., Engineer
Edmund J. Marzec, 3231–4th Ave., Sioux City, Ia., Sanitary Engineer, Woodbury County Health Unit
Joseph J. Mooney, 707 Arbor St., Ann Arbor, Mich., Federal Trainee
Myhren C. Peterson, P. O. Box 443, Bemidji, Minn., District Public Health Engineer, State Dept. of Health

William D. Turner, Ph.D., Box 1, Havemeyer Hall, Columbia University, New York, N. Y., Assistant Professor of Chemical Engineering

Industrial Hygiene Section

Niles R. Bernz, 80 Maiden Lane, New York, N. Y., charge of Industrial Hygiene Division, Fidelity and Casualty Company of New York

John W. Dugger, M.D., Old Capitol Bldg., Jackson, Miss., Director, Division of Industrial Hygiene, State Board of Health

John M. Hepler, C.E., 320 W. Genesee St., Lansing, Mich., Director, Bureau of Industrial Hygiene, Dept. of Health (State)

Saul C. Rothmann, State Department of Health, Charleston, W. Va., Assistant Industrial Hygiene Engineer, Bureau of Industrial Hygiene

Kenneth D. Smith, M.D., 456 Elmwood Dr., Marion, O., Assistant Medical Director, Bureau of Occupational Diseases, State Dept. of Health

Emerson Venable, 414 S. Trenton Ave., Pittsburgh, Pa., Chemist, Dust Laboratory, Mine Safety Appliances Company

Food and Nutrition Section

A. J. Carlson, Ph.D., M.D., LL.D., University of Chicago, Chicago, Ill., Professor of Physiology, University of Chicago

Eugene E. Hamann, D.V.M., Rm. 205, City Hall, Lansing, Mich., Chief Sanitary and Food Inspector

Child Hygiene Section

James W. Chapman, M.D., 902 Broadway, Hannibal, Mo., Acting Director, Hannibal-Marion County Health Unit

Francis V. Corrigan, M.D., 610 Angell, Providence, R. I., Assistant Chief, Bureau of Child Hygiene, State Dept. of Health

Ruth E. Fairbank, M.D., 615 N. Wolfe St., Baltimore, Md., Psychiatrist, charge of Mental Hygiene Study, Johns Hopkins School of Hygiene and Public Health

Paul F. Fletcher, M.D., St. Louis University, School of Medicine, St. Louis, Mo., State Obstetrician

Public Health Education Section

Eva M. Adams, Health Department, Jackson, Miss., Director of Health Education

Theresa E. Boden, 195 Broadway, New York, N. Y., Assistant to Health Director, American Telephone and Telegraph Company

P. Bruce Brockway, M.D., 225 Michigan, Toledo, O., Director, Health Supervision, Board of Education

A. Barklie Coulter, M.D., 1150 Connecticut Ave., N.W., Washington, D. C., Director, Bureau of Tuberculosis, Dept. of Health

Vaikunthrai M. Desai, D.D.S., Central Bank Bldg., Esplanade Rd., Bombay, India, Director, Nair Hospital Dental Clinic

A. Louise Dietrich, R.N., 1001 E. Nevada St., El Paso, Tex., General Secretary, Texas Graduate Nurses Assn.

Margaret C. Klem, Social Security Board, Washington, D. C., Associate Social Statistician

Minnie K. Oed, R.N., 691 Seward Ave., Detroit, Mich., Nurse-Teacher, Health Education, Dept. of Health

Public Health Nursing Section

Margaret Leddy, 3312 Federal St., Camden, N. J., Supervising Nurse, Metropolitan Life Insurance Co.

Kathryn A. Schulte, R.N., 2875 W. 19 St., Chicago, Ill., Teacher, Public Health Nursing

Edith L. Soule, R.N., State Bureau of Health, Augusta, Me., Director, Division of Public Health Nursing

Epidemiology Section

Hollis S. Ingraham, M.D., State Dept. of Health, Albany, N. Y., Assistant Epidemiologist

Gerald N. Rein, M.D., 15715 Park Place N., E. Detroit, Mich., Medical Consultant, U. S. Public Health Service

Unaffiliated

Samuel E. Hershey, D.V.M., Box 283, Charleston, W. Va., Consulting State Veterinarian

Walter M. Smith, M.D., M.P.H., State Board of Health, Little Rock, Ark., Director, Training Center

DECEASED MEMBERS

John B. Derrickson, M.D., Georgetown, Del., Elected Member 1932

Frederick McD. Harkin, M.D., Marquette, Mich., Elected Member 1935

William S. Yates, M.D., Junction City, Kans., Elected Member 1934

APPLICANTS FOR FELLOWSHIP

(*Additions to list published in July Journal*)

HEALTH OFFICERS SECTION

William B. Grayson, M.D., Little Rock, Ark.

Gordon L. Hastings, M.D., M.P.H., Little Rock, Ark.

Norris C. Knight, M D, C P H, Clarksdale, Miss.
Ernest M. Morris, M.D., Fall River, Mass.

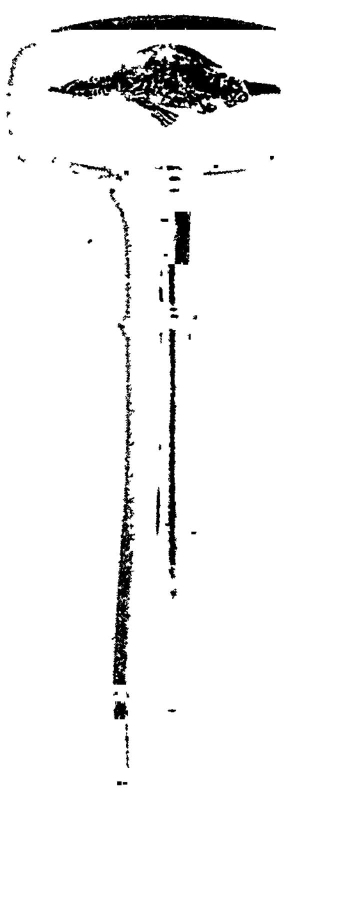
FOOD AND NUTRITION SECTION
Max J Mackler, Ph C, C P.H, Tampa, Fla.

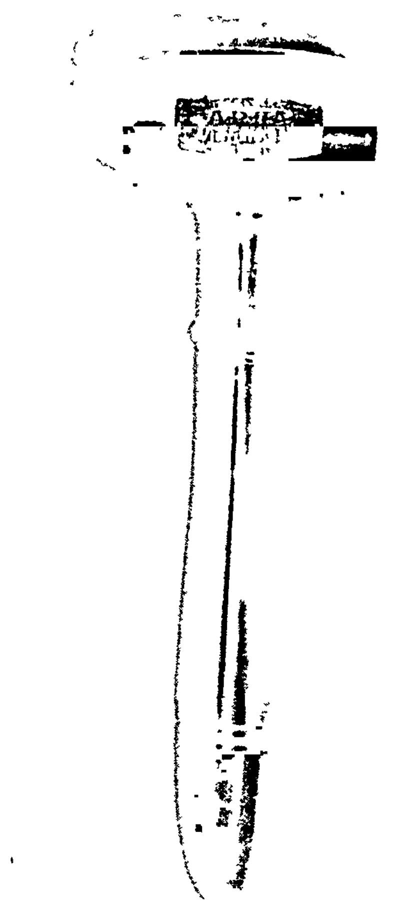
EPIDEMIOLOGY SECTION
Ernest L Stebbins, M D, C P H, Rochester, N Y

LABORATORY SECTION
George A. Denison, M D., Birmingham, Ala.
William H. Gaub, M.S, C.P.H, Nashville, Tenn.
Katherine Marden, M S, Hartford, Conn.

PUBLIC HEALTH EDUCATION SECTION
Adelaide Arfsten, B A., San Francisco, Calif.
Kenneth W. Grimley, M S, Birmingham, Ala
Nathan Sinai, M S, D P H, Ann Arbor, Mich

PHOTOGRAPH OF THE GAVEL PRESENTED TO THE WESTERN BRANCH AMERICAN PUBLIC HEALTH ASSOCIATION BY DR. H. E. YOUNG AT THE ANNUAL DINNER DURING THE SEVENTH ANNUAL MEETING IN VANCOUVER, B. C., JUNE 26, 1936





Seventh Annual Meeting
American Public Health Association (Western Branch)

Vancouver, British Columbia, Canada.
June 24th to 27th, 1936.

Presentation of Gavel.

THE OAK WOOD USED IN THE HEAD OF THE GAVEL PRESENTED TO THE WESTERN BRANCH OF THE AMERICAN PUBLIC HEALTH ASSOCIATION BY THE PRESIDENT-ELECT, DR. H. E. YOUNG, PROVINCIAL HEALTH OFFICER OF BRITISH COLUMBIA, WAS TAKEN FROM THE TIMBERS OF THE S.S. "BEAVER."

History of "Beaver"

Keel laid 1834 at yards of Green, Wigram & Green, Blackwall, England.

"Steam navigation was still in its infancy, but the committee of the Hudson's Bay Company decided to utilize the new mode of transportation for their distant western outposts in the North Pacific. They were motivated chiefly by the necessity of overcoming the difficulty of navigating the Columbia River bar, and by the need for faster and more reliable communications between the outposts than could be guaranteed by sailing-vessels.

"The maritime history of the north-west Pacific for fifty-three years is linked with the career of this sturdy pioneer steamer.

"In order to meet the manifest difficulties of crossing the oceans from the River Thames to the River Columbia, and to meet the primitive and dangerous conditions in the far west, the vessel was constructed with the greatest possible care."—*Norman Hacking: "Early Marine History of British Columbia."*

The woods used in the construction of the ship were oak, elm, teak, and greenheart.

Her engines were made by the firm of Boulton & Watt, they were 35 nominal horse-power each, two engines being used to turn the paddles. Her length was 101 feet 4 inches, while her outside width was 33 feet, her paddle-boxes measuring 6 feet 6 inches each in width. Her register was a trifle over 109 tons, she was armed with 5 nine-pounder guns, and carried a crew of twenty-six men.

Mrs. John Labouchere christened the vessel on May 2nd, 1835. On August 29th of the same year she set sail for the north-west coast of America, her machinery having been placed in position, but her side-wheels being shipped on deck.

On April 10th, 1836, she dropped anchor opposite Fort Vancouver on the Columbia River. Soon afterwards the engineers turned their attention to the engines and we read that they "found them to answer very well."

From the time of her arrival at Fort Vancouver the "Beaver" made many a trip up and down the coast, trading with the Indians, collecting furs, carrying Hudson's Bay officers between their different posts, and taking her part in the establishing of new ones, notably Fort Victoria, which was built in 1843, much of the material and all the supplies for the new fort having been carried in the hold and on the decks of the Company's first steamer. The "Beaver" took part in the establishing of the Colony of British Columbia, when on November 19th, 1858, having taken Governor Douglas, Chief Justice David Cameron, Rear-Admiral Baynes, Matthew Begbie, Capt. John Grant, and a detachment of Royal Engineers to Fort Langley, where commissions were read, oaths administered, and British Columbia was officially proclaimed as a Crown colony.

In 1863 the vessel was leased to the Imperial Government and served until 1870 as a survey-ship under Capt. Daniel Pender, R.N.

Upon return to the Company in 1870 she was extensively repaired. She was converted into a tow-boat in 1874 and sold to a private company. She was badly burned in 1880, sank in Burrard Inlet in 1883, but was repaired and returned to service as solid as ever.

The B.C. Towing and Transportation Company operated her until 1888, when she was again licensed to carry passengers, operating between the different logging camps. While engaged in this service she struck a rock at Prospect Point at the entrance to Vancouver Harbour on the night of July 26th, 1888.

For four years she lay there abandoned to the ravages of souvenir-hunters and the tempestuous elements of the weather, when the swell from the steamer "Yosemite" one day caused her to work loose and fall into the channel, thus losing to posterity one of the most historic hulls on the Pacific Coast.

THE HANDLE OF THE GAVEL IS AFRICAN TIMBER TAKEN FROM A DUNDEE-BUILT WHALER NAMED "JAPAN."

NEWS FROM THE FIELD

MEETINGS IN PORTUGAL AND SPAIN ADJOURNED

DUE to the war in Spain, the meeting of the International Union Against Tuberculosis, which was to be held September 7–10, in Lisbon, Portugal, has been adjourned.

The Third International Congress on Malaria, which was to be held October 12–18, in Madrid, has also been adjourned.

HENRY S. WELLCOME

SIR Henry S. Wellcome, British scientist and explorer, and head of the firm of Burroughs, Wellcome & Co., London, manufacturers of chemicals and drugs, died July 25, at the age of 83.

Sir Henry S. Wellcome was a native of Wisconsin who became a British citizen by naturalization during the World War. He founded the Wellcome Bureau of Scientific Research in 1911 and later the Tropical Research Laboratories and the Gordon Memorial College at Khartoum, Africa. In 1927 he founded the Lady Stanley Maternity Hospital in Uganda, Central Africa. He was internationally known for his researches in pharmacy and allied subjects.

CONFERENCE ON EDUCATIONAL BROADCASTING

THE First National Conference on Educational Broadcasting under the auspices of the United States Office of Education and the Federal Communications Commission will be held in Washington, D. C., December 10, 11, 12, 1936. This conference is widely sponsored by various organizations and is for the purpose of enabling persons who are interested in educational broadcasting to discuss means by which radio may become a more effective instrument for education, both formal and informal. It is planned also to serve as a clearing house for information on the latest technical and professional developments in educational broadcasting and to enable persons representing all phases of the subject to become acquainted and to exchange ideas and experiences. The American Public Health Association has been invited to be represented at this meeting.

CONNECTICUT MARRIAGE LAW

SINCE January 1, 1936, it has been compulsory for men and women desiring a license to marry in Connecticut to have a blood test for syphilis.

Up to July 6, according to the Connecticut State Health Department, about 1 blood test out of every 100 made at the state department of health laboratories had been reported distinctly positive for syphilis.

MOTHERS' MILK PRESERVING PROCESS

PEDIATRICIANS in New York City saw new hope for saving the lives of an increasing number of prematurely born babies when, on July 24, the Mothers' Milk Bureau of the Children's Welfare Federation announced the adoption of a new process of quickly freezing mothers' milk.

The process was invented by Washington Platt, a scientist in the Syracuse, N. Y., research laboratory of The Borden Company, and was clinically tested by Dr. Paul W. Emerson of Boston. It makes it possible for the first time to keep mothers' milk for several months or more, transport it,

and feed it to prematurely born or ill babies without any subsequent action other than thawing and warming.

A license for the use of the new process, without charge, was turned over to the Federation by The Borden Company during ceremonies on July 24. James A. Tobey, Dr.P.H., Director of Health Service of The Borden Company, made the presentation.

RESEARCH FELLOWSHIPS

ACCORDING to *Science,* the British Medical Research Council has announced that three junior fellowships will be offered immediately, for award to qualified medical men wishing to receive training with a view to careers in research work in tropical medicine. Preference will be given to candidates who have already had preliminary experience of methods of research in some branch of medical science and the fellowships will be tenable for three years, the first year to be spent at a school of tropical medicine; the second in doing research in some institution; and the third largely in work under direction at some center in the tropics. Further information can be found in the August 14 issue of *Science,* page 149.

PROGRESS UNDER SOCIAL SECURITY ACT

"AMPLE proof that the Social Security Act is sound and workable is furnished by the progress achieved during the few months it has been in existence. Every state in the Union, plus Alaska, Hawaii, and the District of Columbia, is coöperating with the federal government in one or another of the various activities encouraged by this Act.

"Thirty-four states and the District of Columbia are already coöperating in the program of pensions to needy aged, needy blind, and dependent children. Of these, 32 states have plans which take care of 629,000 aged; 19 states have plans which take care of 185,000 dependent children, and 21 states have plans which take care of 21,000 needy blind. The total number covered under these various plans in the 35 states is 835,000 persons. Although funds were made available by Congress only 4 months ago $25,000,000 will have been granted the states by the end of this month for use in financing these state plans.

"In addition, 14 states have enacted unemployment compensation laws, 12 of which have already been approved by the Board. These 12 laws cover approximately 7,200,000 workers or 40 per cent of the total that will be covered when all the states enact similar laws. . . .

"Every effort has been made not to hamper the forces of recovery now running so strongly. With that end in view the social security program has been adjusted to go into effect by easy stages. . . . Right now we have a million old people over 65 years of age being supported out of public funds. We also have over 3,000,000 employable persons being supported out of public funds. The proportion of the aged who will need to be supported by the government will most certainly continue to increase, if we may judge from the experience of older countries.

"Regardless of whether or not we have a social security act it will still be necessary to maintain persons who become dependent in their old age and it will still be necessary to feed the unemployed. The Social Security Act merely undertakes to make a more equitable and a more systematic distribution of existing costs. In so doing it does not seek to rob life of its challenge, but to provide some minimum protection against those hazards which would otherwise be overwhelming."—Arthur J. Altmeyer, Acting Chairman, Social Security Board. Broadcast June 15, 1936.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

OFFICERS for 1936 elected by the Northern California Public Health Association at its annual meeting are as follows:

President—Earl H. Coleman, M.D., Fresno
President-Elect—W. H. Kellogg, M.D., Berkeley
Vice-President—Louis Olsen, Palo Alto
Treasurer—Helen S. Hartley, Stockton
Secretary—I. O. Church, M.D., Oakland
Representative to the Regional Board of the Western Branch A.P.H.A.—Richard G. Soutar, Jr., M.D., Sacramento
Representative on the Governing Council of the A.P.H.A.—J. C. Geiger, M.D., San Francisco

PERSONALS

LYNN M. GARNER, M.D., member A.P.H.A., Director, Miller County Health Department, Tuscumbia, Mo., was appointed Director of the Greene County Health Department, to succeed John W. Williams, Jr., M.D., member A.P.H.A. Dr. Williams is to take charge of a division of the Missouri State Health Department.

JEAN V. LATIMER, F.A.P.H.A., has recently been appointed to the position of Coördinator of Health Education for the Division of Child Hygiene, Massachusetts Department of Public Health, with offices at Boston.

ROGER W. TRUESDAIL, PH.D., member A.P.H.A., President and Director of the Truesdail Laboratories, Inc., at Los Angeles, Calif., announces the appointment of three new staff members. They are:

C. E. P. Jeffreys, Ph.D., Research Chemist and Bacteriologist. Dr. Jeffreys has been the recipient, for the past 2 years, of a Rockefeller Foundation Grant for Medical Research at the California Institute of Technology. He is one of the "abstractors" of *Chemical Abstracts*.

Marion G. Sharp, Nutritionist.

Irving G. Halpern, Chemist.

J. C. GEIGER, M.D., F.A.P.H.A., Director of Public Health, City and County of San Francisco, Calif., sailed July 21 on the S.S. Mariposa for the South Sea Islands, Australia, and New Zealand, for a vacation. He was accompanied by his wife and daughter.

MATTHEW H. GRISWOLD, M.D., of Kensington, Conn., Health Officer of Berlin, has been appointed public health physician in the Connecticut State Department of Health to specialize in cancer work, a newly created position. The state survey was made possible with funds granted to the State Health Department by the 1935 legislature under a bill sponsored by the Connecticut State Medical Society. Dr. Griswold will coöperate with the Tumor Committee of the State Medical Society in its cancer program. About 16 clinics are now operating at general hospitals in the state, as a result of the Society's program, and others are planned.

ADRIAN L. CARSON, JR., M.D., member A.P.H.A., Health Officer of Fairfax County, Va., has been named Director of the Bureau of Maternal and Child Hygiene of the Virginia State Health Department.

EDWARD M. HOLMES, JR., M.D., member A.P.H.A., of Richmond, Va., has been appointed Health Officer of Fairfax County, to succeed Adrian L. Carson, Jr., M.D.

DR. JOHN A. MALMSTROM has resigned as Health Officer of Virginia, Minn., to return to private practice.

NATALE COLOSI, M.S., PH.D., has been appointed General Director of the Parkway Hospital, New York, N. Y. Dr. Colosi has served as instructor in Bacteriology at New York University College of Medicine and is a member of the teaching staff of Wagner College, Staten Island, New York.

CONFERENCES AND DATES

Aug. 31–Sept. 12, Harvard Tercentenary Conference of Arts and Sciences, Cambridge, Mass.

Sept. 1–4, Annual Conference, Governmental Research Association, Ann Arbor, Mich.

Sept. 2–4, Annual Convention, National Shade Tree Conference, Hotel Statler, Boston, Mass.

Sept. 2–4, Union of Nova Scotia Municipalities, Digby, Nova Scotia.

Sept. 2–4, Annual Meeting, Ontario Municipal Association, Toronto, Ont.

Sept. 7–9, Cancer Institute, University of Wisconsin, Madison, Wis.

Sept. 7–10, International Union Against Tuberculosis, Lisbon, Portugal. *Adjourned because of unrest in Spain.*

Sept. 7–11, Sixtieth Anniversary Meeting, American Chemical Society, Pittsburgh, Pa.

Sept. 7–12, Third World Power Conference, National Power Policy Committee, Department of the Interior Building, Washington, D. C.

Sept. 9–12, Annual Meeting, American Forestry Association, Hotel Lakeside, Eagles Mere, Pa.

Sept. 14–17, Annual Convention, League of California Municipalities, Santa Monica, Calif.

Sept. 14–17, Annual Meeting, California Sewage Works Association, Santa Monica, Calif.

Sept. 15–30, First International Congress of Sanatoria and Private Nursing Homes; Margitsziget, Sanatorium, Budapest, Hungary.

Sept. 21–23, Annual Convention, American Institute of Park Executives and the American Park Society, South Bend, Ind.

Sept. 21–23, Annual Meeting, Rocky Mountain Section—American Water Works Association, Denver, Colo.

Sept. 22–25, Annual Meeting—New England Water Works Association, Pennsylvania Hotel, New York, N. Y.

Sept. 23–25, Annual Meeting of the New York State Association of Dairy and Milk Inspectors, Van Curler Hotel, Schenectady, N. Y.

Sept. 23–26, Mississippi Valley Conference on Tuberculosis, The Mississippi Valley Sanatorium Association, Hotel Pere Marquette, Peoria, Ill.

Sept. 24–25, League of Wisconsin Municipalities, Manitowoc, Wis.

Sept. 28, 29, Third Annual Meeting, Rocky Mountain Tuberculosis Conference, Franciscan Hotel, Albuquerque, N. M.

Sept. 28–30, Public Works Congress—American Society of Municipal Engineers—International Association of Public Works Officials, Toronto, Ont.

Sept. 28–Oct. 1, American Society of Municipal Engineers, Toronto, Ont., Canada.

Sept. 28–Oct. 2, American Hospital Association, Cleveland, Ohio

Sept. 28–Oct. 2, American Assn. of Port Authorities, San Francisco, Calif.

Oct. 1–3, Southern Tuberculosis Conference, Hot Springs, Ark.

Oct. 2, 3, Public Meeting—on Water Supply, Flood Control, and Pollution—of the Interstate Commission on the Delaware River Basin; Buckwood Inn, Shawnee-on-the-Delaware, Pa.

Oct. 5–9, Annual Safety Congress and Exposition, National Safety Council, Atlantic City, N. J.

Oct. 6–12, Fire Prevention Week.

Oct. 9, 10, New York State Sewage Works Association, Geneva, N. Y.

Oct. 10–18, National Dairy Show, National Dairy Assn., Dallas, Tex.

Oct. 12, 13, Canadian Dental Association, Montreal, Que.

Oct. 12–15, Annual Convention—Southwest Section, American Water Works Association, Fort Smith, Ark.

Oct. 12–16, Public Ownership League, Springfield, Ill.

Oct. 12–17, The Dairy Industries Exposition, Atlantic City, N. J.

Oct. 12–18, Third International Congress on Malaria, Madrid, Spain. *Adjourned because of unrest in Spain.*

Oct. 14–16, Annual Convention, Pennsylvania Water Works Association, Haddon Hall, Atlantic City, N. J.

Oct. 14–17, Annual Civil Service Assembly of the United States and Canada, Cincinnati, Ohio.

Oct. 15, 16, Annual Convention—New York Section, American Water Works Assn., Saratoga Springs, N. Y.

Oct. 17–25, Centennial Exposition Dairy Show, Atlantic City, N. J.

Oct. 19–20, Conference of State Sanitary Engineers, New Orleans, La.

Oct. 19–21, Annual Meeting, International City Managers' Association, Richmond, Va.

Oct. 20–23 (Tues., Wed., Thurs., Fri.), Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Oct. 20–23, New Orleans, La.:

- American Association of School Physicians.
- American Association of State Registration Executives.
- Association of Women in Public Health.
- Conference of State Laboratory Directors.
- International Society of Medical Officers of Health.
- National Committee of Health Council Executives.
- State Conference of Sanitary Engineers.

Oct. 21–23, Ontario Hospital Association, Toronto, Ont.

Oct. 21–24, Annual Civil Service Assembly of the United States and Canada, Cincinnati, Ohio

Oct. 23, 24, Annual Convention—New Jersey Section, American Water Works Association—jointly with the New Jersey Association of Water Superintendents; Hotel Ambassador, Atlantic City, N. J.

Oct. 26–28, Annual Meeting—Missouri Valley Section, American Water Works Association, Iowa City, Ia.

Positions Wanted

HEALTH OFFICERS

Physician, M.D. N. Y. Medical College and Flower Hospital; extension course for public health officer, N. Y. State Department of Health; 3 years' urologic service in various New York City hospitals; desires position as health officer or in social hygiene department. A-266

Physician, M.D. University of Nebraska; 13 years' experience as city or county health officer in different sections of the West; desires position as health officer. Prefers West Coast. A-267

Physician, M.D. University of Michigan; Certificate in Education, University of Michigan; brief experience as supervisor of and medical consultant to two health surveys of the U. S. Public Health Service; is interested in a position as health officer or in the field of public health education. A-268

Physician, M.D. Indiana University; C.P.H. Johns Hopkins University; special courses in epidemiology, bio-statistics and public health administration; several years' experience as physician to city health department; desires position as full-time county health officer. A-269

Physician, M.D., Ph.D., University of Minnesota; desires administrative position in the field of public health. Experience includes several years as instructor of obstetrics at a university and five years as director of a Bureau of Maternity, Infancy and Child Hygiene in a county health department. Available now. A-238

Physician, M.D., Western Reserve University, 3 months Health Officers' course at Johns Hopkins; 1 years' experience as instructor of Hygiene and Bacteriology, 4 months as county health officer; desires position as health officer or in the field of research. A-273

LABORATORY

Young woman, M.S. Alabama Polytechnic Institute; special courses in pathology, public health, parasitology and micro-technic; desires position as assistant bacteriologist. L-270

Young woman, B.S. Tufts College; M.S. University of Illinois; Ph.D. Western Reserve University; 4 years' experience as director of city health department laboratory and several years' experience in both commercial and hospital laboratories; desires position doing research or routine in chemistry, biochemistry, bacteriology or serology in public health laboratory. L-272

ENGINEERS

Young man, married, graduate in Civil Engineering, experience with Board of Health of Chicago; desires position in public health engineering. Preferably in the West. E-271

MISCELLANEOUS

Physician, graduate of Washington University Medical School, desires position with state department of public health to do educational writing on mental hygiene, child guidance or venereal diseases. Capable of group instruction in health education. 197

Young man, M.D. Vanderbilt University; Sc.D. Johns Hopkins School of Hygiene and Public Health; Dr.P.H. Harvard University; several years' experience as laboratory instructor and research associate; desires position as epidemiologist or teacher of public health and parasitology. M-263

Physician, M.D. Harvard University; several years' experience as instructor of industrial medicine and as consultant in occupational diseases; desires position in industrial hygiene. A-228

Positions Available

UNITED STATES CIVIL SERVICE EXAMINATIONS

MEDICAL OFFICER, $3,800 A YEAR
ASSOCIATE MEDICAL OFFICER, $3,200 A YEAR
ASSISTANT MEDICAL OFFICER, $2,600 A YEAR

Optional branches.—To become eligible, applicants must qualify in at least one of the following optional branches, *and must state in their applications the branch, or branches, desired:*

1. Cardiology.
2. Cancer diagnosis and treatment.
3. Eye, ear, nose and throat (singly or combined).
4. Genitourinary (urology).
5. Internal medicine and diagnosis.
6. Neuropsychiatry.
7. Pathology and bacteriology.
8. Roentgenology.
9. Surgery—(*a*) General, (*b*) Chest, (*c*) Orthopedic.
10. Tuberculosis.
11. Venereal disease—(*a*) Clinical, (*b*) Public health.
12. Industrial medicine.
13. General practice.

Applications must be on file with the United States Civil Service Commission at Washington, D. C., not later than September 8, 1936.

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

What to Tell the Public About Health

KILL BACTERIA WITH A SLEDGE-HAMMER?

You might ... if you could hit all of them. But think what would happen to your equipment! Most dairies find it easier to use Diversol. Kills bacteria by mere contact ... the only quick-acting sterilizer that never corrodes or damages equipment. Kills bacteria completely because of its grease-penetrating power. Diversol dissolves instantly and completely even in cold water. Leaves no film or scale ... is always dependable.

THE DIVERSEY CORPORATION
53 W. Jackson Blvd., Chicago

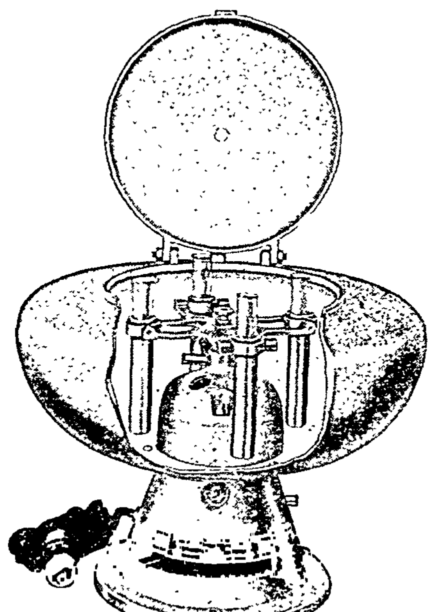
DIVERSOL

The Quick-Acting Sterilizer That Never Rusts Equipment

THE . . .
CLINICAL MODEL

The International "Clinical Model" Centrifuge, with its *built-in* protective guard bowl, operates either a two or four tube head at a full 2,400 R. P. M. with perfect safety. It has a maximum capacity of 200 ml.

The Centrifugal Force of even a small centrifuge at 2,400 R. P. M. calls for a protective guard. For the General Practitioner and as an auxiliary in hospital and research laboratories, the *Clinical Model* (in design and workmanship the equal of the largest International Centrifuge) *is unequalled and yet reasonably priced.*



The Clinical Model

INTERNATIONAL CENTRIFUGES

are made in many sizes to meet the different requirements for speed and capacity. There is an International for any job.

Standard glassware is used in a wide assortment of heads for International Centrifuges—heads holding as many as 96 vials, others with 6 bottles of 500 ml. capacity. Basket type heads are now available in Stainless Steel, Monel Metal, Rubber Coated Steel and Manganese Bronze.

INTERNATIONAL EQUIPMENT CO.
352 Western Avenue Boston, Mass.
Makers of Fine Centrifuges

PRELIMINARY PROGRAM

SIXTY-FIFTH ANNUAL MEETING

American Public Health Association

NEW ORLEANS, OCTOBER 20-23, 1936

THE AMERICAN PUBLIC HEALTH ASSOCIATION
50 West 50th Street New York, N. Y.

TABLE OF CONTENTS

PRELIMINARY PROGRAM OF THE SIXTY-FIFTH ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

New Orleans, La., October 20–23, 1936

THE Annual Meeting Program Committee presents the Preliminary Program of the scientific sessions of the Sixty-fifth Annual Meeting of the American Public Health Association and information concerning meetings of related organizations.

This program is incomplete and perhaps inaccurate in some respects. The affiliations of speakers have been omitted, but will be published in full in the Final Program. Delegates are urged to consult the Final Program, available at the Registration Desk in the Auditorium at the time of the meeting.

Tuesday, 9:30 A.M.

MENTAL HYGIENE

Special Session—Auditorium, Auditorium

Presiding: Grant Fleming, M.D.

The Mental Hygiene Component of Baby Hygiene Clinics in Baltimore. Ruth Fairbank, M.D.

Practicability and Results of Mental Hygiene in a School System. Charles E. Shepard, M.D.

Mental Hygiene in a Public Health Program. W. T. B. Mitchell, M.D.

Practical Aspects of Public Mental Hygiene. B. Liber, M.D.

Mental Hygiene Service in a City Department of Health. Eric Kent Clarke, M.D.

Mental Hygiene in a Provincial Health Department. B. T. McGhie, M.D.

VITAL STATISTICS

First Session—Committee Room 58, Auditorium

Training of Vital Statisticians. John Sundwall, M.D., Ph.D.

The Rôle of Vital Statistics in Medical Science. W. F. Walker, Dr.P.H.

What Is Wrong with Our Computation of Automobile Fatality Rates? Henry L. Porsche and Phillip Stein.

A Preliminary Report of the Health Inventory of Cities. George St. J. Perrott.

Tuesday, 9:30 A.M.

PUBLIC HEALTH ENGINEERING SECTION AND CONFERENCE OF STATE SANITARY ENGINEERS

Joint Session—Concert Hall, Auditorium

Presiding: JOHN H. O'NEILL, *Chairman,* Conference of State Sanitary Engineers.

Résumé of Activities Tending Toward a National Program of Stream Pollution Control. R. E. TARBETT.

The Interstate Sanitation Compact and Its Implications. C. A. HOLMQUIST.

Discussion. ELLIS S. TISDALE and ARTHUR D. WESTON.

Revised Standards for Design and Sanitation of Bathing Places. (Progress Report of the Joint Committee on Bathing Places.) *Chairman,* W. J. SCOTT.

Hot Air Sterilization of Milk Utensils. (Report of the Joint Committee on Milk Supply.) *Chairman,* C. A. HOLMQUIST.

Water Storage, Conditioning and Cleansing of Shellfish. (Report of the Committee on Shellfish.) *Chairman,* L. M. FISHER.

Progress Report of the Joint Committee on Plumbing. *Chairman,* J. I. CONNOLLY.

Announcements.

FOOD AND NUTRITION

First Session—Committee Room 339, Auditorium

Presiding: WALTER S. FRISBIE, *Vice-Chairman,* Food and Nutrition Section.

Report of the Committee on Foods. *Chairman,* B. E. PROCTOR, PH.D.

Problems in Food Preservation. Address of the *Section Chairman,* FRED W. TANNER, PH.D.

Shrimp Inspection. J. O. CLARKE.

Inspection of Cream for Butter Making. SARAH VANCE DUGAN.

Rodent Control in Food Establishments. ROY C. MOORE.

Meat Sanitation. L. B. JENSEN, PH.D.

Use of Apple Powder in the Prevention and Cure of Summer Diarrheas. IRA A. MANVILLE, M.D., PH.D.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

First Session—Assembly Hall North, Auditorium

For program see page 21.

Tuesday, 9:30 A.M.

EPIDEMIOLOGY

First Session—Assembly Hall South, Auditorium

Epidemiological Studies in Influenza. THOMAS FRANCIS, JR., M.D.

New Epidemiological and Immunological Studies of Rabies. LESLIE T. WEBSTER, M.D.

A Contribution to the Epidemiology of Measles. FRANKLIN H. TOP, M.D.

Immunity to Virus Diseases. ERNEST W. GOODPASTURE, M.D.

LABORATORY

First Session—Memorial Hall North, Auditorium

Presiding: RUTH GILBERT, M.D., *Chairman,* Laboratory Section.

Address of the *Chairman* of the Laboratory Section. RUTH GILBERT, M.D.

Section Business:

Report of the Committee on Scientific Exhibits. *Chairman,* FRED O. TONNEY, M.D.

Report of the Committee on Aspects of Veterinary Public Health. *Chairman,* R. V. STONE, D.V.M.

Report of the Committee on Biological Products. *Chairman,* WILLIAM H. PARK, M.D.

Report from Section Archivist. A. B. WADSWORTH, M.D.

Report of the Coördinating Committee on Standard Methods. *Chairman,* MAJOR A. PARKER HITCHENS, M.D.

Report of the Standard Methods Committee on Diagnostic Procedures and Reagents. *Chairman,* W. D. STOVALL, M.D.

Report of Representatives of Committees Outside of the Laboratory Section and Other Special Reports.

Tuesday, 10:30 A.M.

(Second Session—Meeting concurrently in Memorial Hall South, Auditorium)

The Virus of Lymphogranuloma Inguinale. RIGNEY D'AUNOY, M.D.

New Methods for the Laboratory Diagnosis and Treatment of Gonococcal Infections. CHARLES M. CARPENTER, M.D. *(Motion Picture.)*

Tuesday, 10:30 A.M.

LABORATORY

Second Session—Memorial Hall South, Auditorium

(Please note this session begins at 10:30. From 9:30 to 10:30 the Laboratory Section is requested to convene in Memorial Hall North for the conduct of section business.)

Presiding: W. D. STOVALL, M.D., *Vice-Chairman*, Laboratory Section.

A Laboratory Technic for Sanitary Air Analysis. W. F. WELLS.

Normal Sheep Cell Amboceptor in Wassermann Sera. C. A. STUART, PH.D., and HENRY WELCH, PH.D.

Human Deaths from Rabies and the Efficacy of Rabies Vaccine. Author to be selected.

Rabies in Louisiana. RIGNEY D'AUNOY, M.D., and JOHN H. CONNELL, M.D.

Tuesday, 12:30 P.M.

INDUSTRIAL HYGIENE

Luncheon Session—Room E, Hotel Roosevelt

Report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases. *Chairman*, HENRY H. KESSLER, M.D., PH.D.

PUBLIC HEALTH EDUCATION

Luncheon Session—Dome Room, Hotel Roosevelt

Presiding: W. W. BAUER, M.D., *Chairman*, Public Health Education Section.

Use of the Department in the Journal Devoted to Health Education. EVART G. ROUTZAHN.

DIPHTHERIA IMMUNIZATION

Luncheon Session—Tip Top Room, Hotel Roosevelt

Preliminary Report of the Committee on Diphtheria Immunization Study.

EDWARD S. GODFREY, M.D.
DONALD T. FRASER, D.P.H.
V. K. VOLK, M.D.
G. FOARD MCGINNES, M.D.
WILLIAM H. PARK, M.D.
WALTER T. HARRISON, M.D.
W. E. BUNNEY, PH.D.

Tuesday, 2:30 P.M.

STATE REGISTRATION EXECUTIVES

Assembly Hall North, Auditorium

ADVANCES IN PUBLIC HEALTH

Special Session—Concert Hall, Auditorium

Presiding: ROBERT E. WODEHOUSE, M.D.

Recent Advances in Administrative Technic. HENRY F. VAUGHAN, DR.P.H.

Recent Advances in the Control of Pneumonia. RUFUS COLE, M.D.

Recent Trends in Engineering Practice. ABEL WOLMAN.

Recent Progress in Health Education Methods. WILLIAM P. SHEPARD, M.D.

Recent Contributions to Laboratory Methods. W. D. STOVALL, M.D.

Housing as a Public Health Problem. C.-E. A. WINSLOW, DR.P.H.

Tuesday, 6:30 P.M.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Dinner Session—Gold Room, Hotel Roosevelt

Tuesday, 7:00 P.M.

SOUTHERN BRANCH—AMERICAN PUBLIC HEALTH ASSOCIATION

Dinner—Tip Top Room, Hotel Roosevelt

Tuesday, 8:00 P.M.

FIRST GENERAL SESSION

Concert Hall, Auditorium

Invocation. DEAN W. H. NES, Christ Church Cathedral, New Orleans, La.

Addresses of Welcome:
J. M. BATCHELOR, M.D.
ALFRED D. DANZIGER
J. A. O'HARA, M.D.
F. R. GOMILA, M.D.

Address of the President-elect of the American Public Health Association. THOMAS PARRAN, M.D.

Announcement of the Sedgwick Memorial Medal Award

Reception to the President and the President-elect.

Dancing.

Wednesday, 8:00 A.M.

YALE ALUMNI

Breakfast Session—Room E, Hotel Roosevelt

HARVARD UNIVERSITY ALUMNI

Breakfast Session—Room G, Hotel Roosevelt

Wednesday, 9:30 A.M.

HEALTH OFFICERS

First Session—Concert Hall, Auditorium

Statistical Study of Deaths in New Orleans since 1850. A. E. FOSSIER, M.D.

Discussion. J. M. BATCHELOR, M.D.

Relation of Bovine Mastitis to Human Disease. PAUL B. BROOKS, M.D., and WALTER VON D. TIEDEMAN.

The Need for and Value of an Intensive Program of Health Education in State Health Departments. FELIX J. UNDERWOOD, M.D.

Public Health Problems in Leprosy. H. E. HASSELTINE, M.D.

PUBLIC HEALTH ENGINEERING

First Session—Memorial Hall South, Auditorium

Observations on the Use of Copper and Chloramines in Water Purification. A. E. GRIFFIN.

Institutional and Other Small Water Treatment Plants to Meet Unusual Conditions. F. R. SHAW.

Further Study of Water-borne Typhoid Fever Outbreaks—1930-1935. (Report of the Committee on Water Supply.) *Chairman,* A. E. GORMAN.

Recent Developments Regarding Disposal of Pulp and Paper Mill Wastes. C. M. BAKER.

Discussion. C. E. GREEN.

Progress Report of the Committee on Waterways Pollution. *Chairman,* L. F. WARRICK. To be presented by title only.

Section Business.

Report of the Section Committee on Fellowship and Membership. *Chairman,* MORRIS COHN.

Public Health Engineering Content of an American Museum of Hygiene. GORDON M. FAIR.

Report of Section Nominating Committee and Election of Officers.

Wednesday, 9:30 A.M.

LABORATORY

Third Session—Committee Room 103—Auditorium

Presiding: RUTH GILBERT, M.D., *Chairman*, Laboratory Section.

International Biological Standardization. GEORGE W. MCCOY, M.D.

Laboratory Problems in the Control of Meningococcus Meningitis. ROSS L. LAYBOURN.

Laboratory Diagnosis of Meningitis Outbreaks. MAJOR A. PARKER HITCHENS, M.D.

Culturing of Meningococci. LUTHER THOMPSON, PH.D.

Active and Passive Immunization Against Tularemia. H. J. SHAUGHNESSY, PH.D., T. C. GRUBB, and ALBERT C. FAUTH.

The Standardization of Typhoid and Paratyphoid Vaccines. 1. The Value of the Gates Apparatus and Total Nitrogen Determination. ROY F. FEEMSTER, M.D., DR.P.H., LESLIE H. WETTERLOW, B.S., and JOSEPH CIANCIARULO, PH.C.

The Growth of Bacteria in Body Fluids. ANNA DEAN DULANEY, PH.D.

The Current Incidence of C. Diphtheriae Mitis and Gravis. (*Illustrated.*) JOHN L. WHITE, M.D.

INDUSTRIAL HYGIENE

First Session—Committee Room 339, Auditorium

Address of the Chairman. ALBERT S. GRAY, M.D.

Review of Research Methods and Progress in Industrial Sanitation. THEODORE HATCH.

Industrial Hygiene Study of Foundry Industry in New York State. LEONARD GREENBURG, M.D., PH.D.

Compensation Aspects of Occupational Diseases. WESLEY GRAFF.

Importance of the Supervisor in the Industrial Health Program. LEVERETT D. BRISTOL, M.D.

Section Business.

PUBLIC HEALTH EDUCATION

First Session—Memorial Hall North, Auditorium

The Newspaper-Science in the Press—The Daily, the Weekly, and the Interests of the Readers of Each. HOWARD BLAKESLEE.

Discussion.

The Radio. JUDITH WALLER.

Discussion. ELIZABETH C. NICKERSON and HENRY F. VAUGHAN, DR.P.H.

Wednesday, 9:30 A.M.

FOOD AND NUTRITION AND LABORATORY SECTIONS

Joint Session—Auditorium, Auditorium

SYMPOSIUM ON MILK AND DAIRY PRODUCTS

Presiding: FRED W. TANNER, PH.D., *Chairman,* Food and Nutrition Section and ROBERT S. BREED, PH.D., *Chairman,* Standard Methods Committee on Milk and Dairy Products.

Regulations, Standards and Manufacturing of Ice Cream. (Report of Committee on Milk and Dairy Products, Food and Nutrition Section.) F. W. FABIAN, PH.D.

Discussion. W. B. PALMER, *Chairman.*

Methods and Significance of Cream and Butter Sediment Test. E. H. PARFITT.

Some Problems in the Sanitary Control of Counter Ice Cream Freezers. C. A. ABELE.

Proposed Changes in the Standard Methods for the Examination of Milk. ROBERT S. BREED, PH.D.

Report of the Committee on Vitamin D Milk. *Chairman,* E. M. NELSON, PH.D.

CHILD HYGIENE

First Session—Assembly Hall South, Auditorium

Maternal Mortality at the Chicago Maternity Center. BEATRICE E. TUCKER, M.D., and HARRY B. W. BENARON, M.D.

Infant Mortality in New York City. JOHN L. RICE, M.D., MARGARET W. BARNARD, M.D., THOMAS J. DUFFIELD, and JULES BLUMENTHAL, M.D.

Infant and Maternal Welfare from the Aspect of Social Security. MARTHA ELIOT, M.D.

PUBLIC HEALTH NURSING

First Session—Assembly Hall North, Auditorium

Section Business.

State Problems—Final Report of the Committee to Study Public Health Nursing in State Health Departments. MARIAN SHEAHAN, R.N.

Discussion. PEARL MCIVER, R.N., and NAOMI DEUTSCH, R.N.

Content for Section in American Museum of Hygiene.

STATE REGISTRATION EXECUTIVES

Committee Room 58, Auditorium

Wednesday, 12:30 P.M.

PUBLIC HEALTH EDUCATION

Luncheon Session—Dome Room, Hotel Roosevelt

Presiding: W. W. BAUER, M.D., *Chairman,* Public Health Education Section.

Public Health Around the World. CLAIR E. TURNER, DR.P.H.

DELTA OMEGA

Luncheon Session—Gold Room, Hotel Roosevelt

Wednesday, 2:30 P.M.

LABORATORY

Fourth Session—Assembly Hall South, Auditorium

SYMPOSIUM ON ENTERIC FEVERS

Presiding: W. D. STOVALL, M.D., *Vice-Chairman,* Laboratory Section, and MARION B. COLEMAN, *Referee,* for Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers.

Typhoid Vaccine Studies: II. Protective Antibodies in the Blood Serum of Vaccinated Individuals. Laboratory Staff of the Army Medical School, Washington, D. C. Presented by COLONEL J. F. SILER.

Discussion: T. F. SELLERS, M.D.

A Study of the Antigenic Fraction of Typhoid Bacilli Isolated from Carriers and Cases and the Antibody Content of the Serum of These Patients. LOIS ALMON and W. D. STOVALL, M.D.

Discussion: A. L. MACNABB, D.V.M.

Practical Procedures in the Laboratory Diagnosis of Typhoid and Related Fevers. T. F. SELLERS, M.D.

Discussion: RUTH GILBERT, M.D., and ROSS L. LAYBOURN.

Bacillary Dysentery in the United States. A. V. HARDY, M.D.

Discussion: G. FOARD MCGINNES, M.D., and ROSS L. LAYBOURN.

VI Antigen in Carrier Strains of Eberthella Typhosa. HENRY WELCH, PH.D., and FRIEND LEE MICKLE, SC.D.

Standards for Determining the Suitability of Bile Specimens for Detection or Release of Typhoid Carriers. F. C. FORSBECK, M.D., and HARRIET C. HOLLON.

Discussion: RUTH GILBERT, M.D.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Second Session—Concert Hall, Auditorium

For program see page 21.

Wednesday, 2:30 P.M.

VITAL STATISTICS

Second Session—Committee Room 58, Auditorium

Report of the Committee on Accident Statistics. ROBERT J. VANE, *Acting Chairman.*

Report of the Committee on Forms and Methods of Statistical Practice. *Chairman,* A. W. HEDRICH, SC.D.

Report of the Committee on Registration of Births Out of Wedlock. *Chairman,* J. V. DEPORTE, PH.D.

Report of the Committee to Study Death Certification. *Chairman,* MARJORIE T. BELLOWS.

Report of the Committee on Scientific Exhibits. *Chairman,* JESSAMINE S. WHITNEY.

Report of the Section Committee on American Museum of Hygiene.

Report of the Nominating Committee.

Reports are to be submitted in writing to the Secretary of the Vital Statistics Section and distributed prior to the meeting. The time will be devoted to discussion.

Election of Officers.

Suggestions for Improvement of Vital Statistics Section and Programs.

PUBLIC HEALTH ENGINEERING

Second Session—Memorial Hall South, Auditorium

Inaugurating Grade A Pasteurized Milk in the City of Chicago. HERMAN N. BUNDESEN, M.D.

Discussion. LESLIE C. FRANK.

Public Health Features in Milk Plant Layout. RALPH E. IRWIN.

Discussion. GEORGE W. PUTNAM.

A Study of Air Pollution in New York City. SOL PINCUS.

Discussion. E. B. PHELPS.

Report of the Committee on Sewage Disposal. *Chairman,* LANGDON PEARSE.

Report of the Committee on Municipal Public Health Engineering. *Chairman,* WILLIAM H. CARY, JR.

Report of the Committee on Promotion of Environmental Sanitation. *Chairman,* V. M. EHLERS.

Progress Report of the Committee on Summer Camps and Roadside Places. *Chairman,* E. D. RICH.

Wednesday, 2:30 P.M.

FOOD AND NUTRITION

Second Session—Assembly Hall North, Auditorium

Presiding: FRED W. TANNER, PH.D., *Chairman,* Food and Nutrition Section.

Mineral Elements in Metabolism. (*Report of Committee on Nutritional Problems.*) *Chairman,* D. B. JONES, PH.D.

Nutritional-Economics of Dietetic Calcium. F. L. GUNDERSON, PH.D.

Fundamentals of Dental Health. GUY S. MILLBERRY, D.D.S., and NINA SIMMONDS, D.Sc.

Recent Trends in Pellagra. WILLIAM DEKLEINE, M.D.

Rationale of Antirachitic Procedure. FRED O. TONNEY, M.D.

The Question of Acid and Alkaline Forming Foods. J. A. TOBEY, DR.P.H.

Diet and Resistance to Infection. A Review of Recent Studies. CHARLES F. CHURCH, M.D.

HEALTH OFFICERS, EPIDEMIOLOGY AND LABORATORY SECTIONS

Joint Session—Auditorium, Auditorium

SYMPOSIUM ON SYPHILIS

Presiding: JOHN P. KOEHLER, M.D., *Chairman,* Health Officers Section, KENNETH F. MAXCY, M.D., DR.P.H., *Chairman,* Epidemiology Section, and RUTH GILBERT, M.D., *Chairman,* Laboratory Section.

Administrative Aspects. J. N. BAKER, M.D.

Epidemiological Aspects. GEORGE H. RAMSEY, M.D.

Laboratory Aspects. A. H. SANFORD, M.D.

Discussion: To be opened by THOMAS PARRAN, M.D.

Wednesday, 6:30 P.M.

PUBLIC HEALTH ENGINEERING SECTION AND CONFERENCE OF STATE SANITARY ENGINEERS

Dome Room, Hotel Roosevelt

Annual Engineers Stag Dinner.

WILLIAM J. ORCHARD, *Toastmaster.*

PUBLIC HEALTH EDUCATION

Dinner Session—Room E, Hotel Roosevelt

Presiding: W. W. BAUER, M.D., *Chairman,* Public Health Education Section.

Business Session.

Wednesday, 6:30 P.M.

HEALTH OFFICERS

Dinner Session—Tip Top Room, Hotel Roosevelt

Presiding: JOHN P. KOEHLER, M.D., *Chairman*, Health Officers Section, and J. N. BAKER, M.D.

Thursday, 8:00 A.M.

JOHNS HOPKINS ALUMNI

Breakfast Session—Room E, Hotel Roosevelt

MASSACHUSETTS INSTITUTE OF TECHNOLOGY ALUMNI

Breakfast Session—Room G, Hotel Roosevelt

ASSOCIATION OF SCHOOL PHYSICIANS

Breakfast Session—Room C, Hotel Roosevelt

Thursday, 9:30 A.M.

VITAL STATISTICS SECTION AND STATE REGISTRATION EXECUTIVES

Joint Session—Memorial Hall North, Auditorium

TESTS AND PROMOTION OF REGISTRATION OF BIRTHS AND DEATHS AND INTERPRETATION OF THEIR SIGNIFICANCE

Presentation of Problem and Methodology of Past—Federal and State. W. J. V. DEACON, M.D.

Analysis of Experiences Gleaned from Morbidity Surveys. SELWYN D. COLLINS, PH.D.

Survey of Methods of Testing Completeness of Registration. LOWELL J. REED, PH.D.

Institutional Mortality with Reference to Residence Allocation. ELIZABETH PARKHURST.

Proper Distribution and Duties of County and Local Registrars. LEONARD V. PHELPS.

CHILD HYGIENE

Second Session—Memorial Hall South, Auditorium

Round Table Discussion of Maternal and Child Health Problems with a View of Developing Greater Coöperation of Various Public and Private Agencies.

Business Meeting.

Thursday, 9:30 A.M.

LABORATORY

Fifth Session—Committee Room 103, Auditorium

Presiding: RUTH GILBERT, M.D., *Chairman,* Laboratory Section, ROBERT S. BREED, PH.D., and JOHN F. NORTON, PH.D.

Report of the Committee on Water Pollution Studies. *Chairman,* JAMES A. NEWLANDS.

Report of the Standard Methods Committee on Examination of Water and Sewage. *Chairman,* JOHN F. NORTON, PH.D.

Report of the Standard Methods Committee on Examination of Dairy and Food Products. *Chairman,* ROBERT S. BREED, PH.D.

Report of the Committee on Milk Pasteurization Studies. *Chairman,* GEORGE J. HUCKER, PH.D.

Nomenclature for the Colon Group. JOHN F. NORTON, PH.D., and ROBERT S. BREED, PH.D.

A Comparison of Solid with Liquid Media as a Means of Determining the Presence of Lactose Fermenting Bacteria in Pasteurized Milk. M. W. YALE, PH.D.

The Bacteriology of Septic Sore Throat Epidemics. GEORGE J. HUCKER, PH.D.

Discussion: JULIA M. COFFEY and JAMES G. MCALPINE, PH.D.

A Comparison of the Standard with the Modified Methylene Blue Reduction Technic. H. R. THORNTON, PH.D.

The Standardization of Tablets for Determining Methylene Blue Reduction in Milk. H. J. CONN, PH.D.

HEALTH OFFICERS AND PUBLIC HEALTH NURSING SECTIONS AND AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Joint Session—Auditorium, Auditorium

The Use of Lay Boards by Official Health Agencies. OLIVIA PETERSON, R.N.

Discussion. BURKE DIEFENDORF, M.D.

The Control of Pneumococcus Pneumonia. EDWARD S. ROGERS, M.D.

Care of Communicable Disease in the Home.

Public Health Nursing. ALMA C. HAUPT, R.N.

Health Officer. JOHN J. SIPPY, M.D.

Illinois School Health Activities. FRANK J. JIRKA, M.D.

Thursday, 9:30 A.M.

LABORATORY AND FOOD AND NUTRITION SECTIONS

Joint Session—Assembly Hall North, Auditorium

SYMPOSIUM ON FOOD POISONING

Presiding: FRED W. TANNER, PH.D., *Chairman,* Food and Nutrition Section, and STEWART A. KOSER, PH.D., *Referee,* Laboratory Diagnostic Procedures in the recognition of Various Food Poisonings, representing the Laboratory Section.

Consumer Claims and Their Economic Importance to the Food Processing Industries. R. W. PILCHER, PH.D.

Epidemiology and Symptomatology of Staphylococcus Food Poisoning: A Report of Recent Outbreaks. GEORGE A. DENISON, M.D.

Staphylococci in Relation to Food Poisoning. G. M. DACK, PH.D., M.D.

Factors Affecting the Production and Potency of Staphylococcic Toxins. G. J. HUCKER, PH.D., and W. C. HAYNES.

Foods—The Importance of Preventing the Addition of Medicinal Substances and the Necessity for Keeping Foreign Material, and Added Poisons to a Minimum Amount. GEORGE H. MARSH.

Committee Report from Laboratory Section on Advisability of Laboratory Examination of Food Handlers. *Chairman,* MINNA CROOKS YOUNG.

Discussion. FRED W. TANNER, PH.D., and LEON BANOV, M.D.

INDUSTRIAL HYGIENE AND PUBLIC HEALTH ENGINEERING SECTIONS

Joint Session—Concert Hall, Auditorium

Presiding: A. P. MILLER, *Chairman,* Public Health Engineering Section, and ALBERT S. GRAY, M.D., *Chairman,* Industrial Hygiene Section.

The Application of Engineering Surveys to the Hatters' Fur Cutting Industry. J. J. BLOOMFIELD and J. M. DALLA VALLE.

Rôle of the Public Health Engineer in Industrial Hygiene and Sanitation. W. SCOTT JOHNSON.

Report of the Committee on Industrial Sanitation of the Public Health Engineering Section. *Chairman,* C. L. POOL.

Program of the Foundry Industry for Dust Control. E. O. JONES.

Industrial Hygiene Activities in the United States. R. R. SAYERS, M.D.

Section Business.

Thursday, 9:30 A.M.

EPIDEMIOLOGY

Second Session—Assembly Hall South, Auditorium

Active Immunization Against Whooping Cough: Interim Report of the Cleveland Experience. J. A. DOULL, M.D., and Associates.

The Epidemiology of Rural Tuberculosis. A. H. GRAHAM, M.D.

Reaction of Young Adults to Alum Precipitated Diphtheria Toxoid. RUTH E. BOYNTON, M.D., and RALPH V. ELLIS, M.D.

The Nature of Autarceologic Susceptibility to Poliomyelitis. W. LLOYD AYCOCK, M.D.

Thursday, 12:30 P.M.

COMMITTEE ON PROFESSIONAL EDUCATION

Special Luncheon—Dome Room, Hotel Roosevelt

Presiding: W. S. LEATHERS, M.D., *Chairman,* Committee on Professional Education.

Title to be announced. MILTON J. ROSENAU, M.D.

FOOD AND NUTRITION

Luncheon Session—La Louisiane

Thursday, 7:00 P.M.

SECOND GENERAL SESSION

Banquet—Tip Top Room, Hotel Roosevelt

The Dynamics of Public Health. HENRY E. SIGERIST, M.D.

Recognition of Members Joining the Association before 1897.

Announcement of Health Conservation Contest Awards.

Dancing.

Friday, 9:30 A.M.

INDUSTRIAL HYGIÈNE

Second Session—Memorial Hall South, Auditorium

Pneumonia and Tuberculosis Among Industrial Workers and Their Dependents. C. H. KIBBEY, M.D.

Industrial Morbidity and Mortality. D. K. BRUNDAGE.

Manganese Poisoning in Industry. W. D. MCNALLY, M.D.

Health Hazards in the Dry-Cleaning Industry. WILLIAM H. CARY, JR., and JOHN M. HEPLER.

Friday, 9:30 A.M.

VITAL STATISTICS

Third Session—Committee Room 58, Auditorium

The Prevention of Accidents as a Health Department Activity. EDWARD S. GODFREY, JR., M.D.

Uses of Life Tables in Vital Statistics Work. LOUIS I. DUBLIN, PH.D., and ALFRED J. LOTKA, D.SC.

A Statistical Study of Stillbirths in Hospitals. ELIZABETH C. TANDY, D.SC.

Measurement of Error of Death Rates in the Colored Race. RUTH PUFFER.

LABORATORY, FOOD AND NUTRITION AND PUBLIC HEALTH ENGINEERING SECTIONS

Joint Session—Concert Hall, Auditorium

SYMPOSIUM ON THE SANITATION OF EATING UTENSILS

Presiding: MAJOR A. PARKER HITCHENS, *Chairman,* Committee on the Sanitation of Eating Utensils; FRED W. TANNER, PH.D., *Chairman,* Food and Nutrition Section, and A. P. MILLER, *Chairman,* Public Health Engineering Section.

The Epidemiological Basis for Demanding Clean Dishes. LEON BANOV, M.D.

The Bacteriological Basis for Demanding Clean Dishes. STUART MUDD, M.D.

A Standard Technic for the Bacteriological Examination of Eating Utensils and Wash Water. LIEUTENANT COLONEL JAMES GORDON CUMMING, M.D., DR.P.H.

A Standard Technic for the Use of Test Organism in Determining the Efficiency of Dishwashing Devices. R. V. STONE, D.V.M.

A Proposed Standard Method for the Bacteriological Examination of Glassware and China. C. R. FELLERS, PH.D.

A Critical Study of Various Types of Dishwashing Devices. J. I. CONNOLLY.

A Critical Study of Various Types of Detergents and Disinfectants Recommended for Use in Dishwashing. W. L. MALLMANN, PH.D.

The Administrative Control of Dishwashing. GEORGE C. RUHLAND, M.D.

Report of the Committee on the Sanitation of Eating Utensils. *Chairman,* MAJOR A. PARKER HITCHENS.

Friday, 9:30 A.M.

LABORATORY

Sixth Session—Memorial Hall North, Auditorium

SYMPOSIUM ON INTESTINAL PARASITES INCLUDING PROTOZOA

Presiding: RUTH GILBERT, M.D., *Chairman,* Laboratory Section, and W. D. STOVALL, M.D., *Vice-Chairman.*

The Laboratory Diagnosis of Amebiasis. W. H. KELLOGG, M.D.

The Practical Value and Significance of the Complement-Fixation Reaction in Amebiasis. HENRY E. MELENEY, M.D., and WILLIAM W. FRYE, PH.D.

Some Observations on the Practical Value of the Complement-Fixation Test in the Diagnosis of Amebiasis. CHARLES F. CRAIG, M.D., M.A. (Hon.), Col. U. S. Army, Retired.

The Decline of Amebic Dysentery in Chicago. A Study of Cyst Varieties During and Following the Chicago Epidemic of Amebic Dysentery. BERTHA KAPLAN SPECTOR, PH.D.

Intestinal Parasite Survey in Alabama. I. A Comparative Study of Two Hookworm Anthelmintics. W. H. Y. SMITH, M.D., J. G. MCALPINE, PH.D., and D. G. GILL, M.D., D.P.H.

Tapeworm Infestations in the Southern United States. T. F. SELLERS, M.D., and E. J. SUNKES.

Laboratory Procedures as Aids in the Diagnosis of Trichinosis. LUCY HEATHMAN, PH.D., M.D.

PUBLIC HEALTH EDUCATION AND CHILD HYGIENE SECTIONS

Joint Session—Auditorium, Auditorium

SCHOOL HEALTH EDUCATION

Presiding: W. W. BAUER, M.D., *Chairman,* Public Health Education Section.

A Modern Concept of Education. FANNIE B. SHAW.

Discussion. A. D. BROWNE, M.D.

The Function of the School in the Rural Program. RUTH GROUT.

Discussion. CARA L. HARRIS.

Appraising the Educational Content of a Health Service Program. GEORGE T. PALMER, DR.P.H., and MAYHEW DERRYBERRY, PH.D.

Friday, 9:30 A.M.

HEALTH OFFICERS

Second Session—Assembly Hall North, Auditorium

The Development of Full-Time District Health Administration in Mexico. JOSÉ SIUROB, M.D.

City Health Department Work in the Field of Housing. L. M. GRAVES, M.D.

Points of Interest in a Survey of Maternal Mortality. J. D. DOWLING, M.D.

International Health Indices. I. S. FALK, PH.D.

Actions of Health Officers Invalidated by the Courts. JAMES A. TOBEY, DR.P.H.

PUBLIC HEALTH NURSING SECTION AND AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Joint Session—Assembly Hall South, Auditorium

N.O.P.H.N. Survey and the School Nursing Situation. DOROTHY DEMING, R.N.

School Nursing in a Generalized Nursing Program. GRACE ROSS, R.N.

Discussion. AMELIA GRANT, R.N.

Development and Correction of Defective Speech in Children. FREDERICK VAN DOREN MARTIN, M.D.

Advantages of Nursery Schools. C. L. OUTLAND, M.D.

Friday, 12:30 P.M.

BUSINESS PROBLEMS OF THE HEALTH DEPARTMENT

Special Luncheon—Dome Room, Hotel Roosevelt

ROUND TABLE CONFERENCE

Presiding: WALTER N. KIRKMAN.

Health Department Financing and Social Security Budgets

Property Accounting in a State Health Department

Questions, Answers, and Discussion.

Friday, 2:30 P.M.

MOSQUITO-BORNE DISEASES

Special Session—Concert Hall, Auditorium

Presiding: CHARLES F. CRAIG, Colonel, U. S. Army, Ret.

Newer Epidemiology of Yellow Fever. FRED L. SOPER, M.D.

Malaria Control—Some Comments on the Past and Future. T. H. D. GRIFFITTS, M.D.

Discussion. A. H. FLETCHER, and S. L. WADLEY, M.D., C.P.H.

Friday, 2:30 P.M.

PUBLIC HEALTH EDUCATION

Second Session—Assembly Hall South, Auditorium

CLINIC ON PUBLICITY MATERIAL

(Criteria will be furnished by which the audience may evaluate samples shown.)

Literature. H. E. KLEINSCHMIDT, M.D.

Exhibit Material. THOMAS G. HULL, M.D.

Radio—Electrically Transcribed. BURT R. RICKARDS.

CHILD HYGIENE SECTION AND AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Joint Session—Assembly Hall North, Auditorium

The Place of Physical Education in Schools. VAUGHN S. BLANCHARD.

Discussion. JESSIE R. GARRISON.

Some Experiences with Vitamin D with Children. PAUL A. ROTHFUSS, M.D.

Heliotherapy in Its Application to Conditions Found in School Children. CHARLES J. BLOOM, M.D.

The Economic Factor in School Child Health. WALTER S. CORNELL, M.D.

MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Tuesday, 9:30 A.M. First Session—Assembly Hall North, Auditorium

Presidential Address. CHARLES C. WILSON, M.D.

School Health Administration. EDWARD S. GODFREY, M.D.

Health Service in Schools. FELIX J. UNDERWOOD, M.D.

Dental Care for Children. WALTER T. McFALL, D.D.S.

Wednesday, 2:30 P.M. Second Session—Concert Hall, Auditorium

Study of Child's Sleep. GLENVILLE GIDDINGS, M.D.

Some Experiences with Tonsillectomy. J. L. BOWMAN, M.D.

Health Education. FANNIE B. SHAW.

Thursday, 8:00 A.M. Room C, Hotel Roosevelt. Business Session. Breakfast.

Thursday, 9:30 A.M. Auditorium, Auditorium. Joint Session with Health Officers and Public Health Nursing Sections. (See page 15.)

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Friday, 9:30 A.M. Assembly Hall South, Auditorium. Joint Session with Public Health Nursing Section. (See page 20.)

Friday, 2:30 P.M. Assembly Hall North, Auditorium. Joint Session with Child Hygiene Section. (See page 21.)

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Tuesday, 6:30 P.M. Gold Room, Hotel Roosevelt. Dinner.

CONFERENCE OF STATE LABORATORY DIRECTORS

Monday, October 19, 10:30 A.M. Room A, Hotel Roosevelt

Monday, 12:30 P.M. Room C, Hotel Roosevelt. Luncheon.

Monday, 2:30 P.M. Room A, Hotel Roosevelt

DELTA OMEGA

Wednesday, 12:30 P.M. Gold Room, Hotel Roosevelt. Luncheon.

HARVARD UNIVERSITY ALUMNI

Wednesday, 8:00 A.M. Room G, Hotel Roosevelt. Breakfast.

CONFERENCE OF STATE SANITARY ENGINEERS

Monday, October 19, 9:30 A.M. Memorial Hall North, Auditorium

Monday, 2:30 P.M. Memorial Hall North, Auditorium

Tuesday, 9:30 A.M. Concert Hall, Auditorium. Joint Session with Public Health Engineering Section. (See page 4.)

Wednesday, 6:30 P.M. Dome Room, Hotel Roosevelt. Annual Engineers' Stag Dinner.

JOHNS HOPKINS ALUMNI

Thursday, 8:00 A.M. Room E, Hotel Roosevelt. Breakfast.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY ALUMNI

EXHIBITORS AT THE SIXTY-FIFTH ANNUAL MEETING

The following will present exhibits of products and equipment of value in health protection and promotion:

American Institute of Laundering
The Borden Company
Carnation Milk Sales Company
Difco Laboratories, Inc.
Eisele & Company
The J. B. Ford Sales Company
Fruit Dispatch Company
Geuder, Paeschke & Frey Company
Gilliland Laboratories
Golden Guernsey, Inc.
Hanovia Chemical & Manufacturing Company
Horlick's Malted Milk Company
Hygeia, The Health Magazine
Irradiated Evaporated Milk Institute
Jackson Brewing Company
Kellogg Company
Krim-Ko Company
Lederle Laboratories, Inc.
Libby, McNeill & Libby
Louisiana Department of Conservation
The Macmillan Company
J. A. Majors Company
Metropolitan Life Insurance Company
National Dairy Council
National Live Stock and Meat Board
Pet Milk Sales Company
Philip Morris & Co., Ltd., Inc.
Precision Scientific Company
E. R. Squibb & Sons
Vitex Laboratories, Inc.
Wallace & Tiernan Co., Inc.
The Wander Company
Winthrop Chemical Company, Inc.
Wisconsin Alumni Research Foundation

GENERAL INFORMATION

MEETING HEADQUARTERS

The Municipal Auditorium in New Orleans is official headquarters for the 65th Annual Meeting. All scientific sessions, except meal-time meetings, will be held here. Here also the commercial and scientific exhibits, registration and information will be established, as well as Association Offices, and Health Education and Publicity Center.

BREAKFASTS, LUNCHEONS, AND DINNERS

Most of these will be held in the Hotel Roosevelt. A few will be scheduled at some of the French restaurants, famous for Creole cooking.

HOTELS

While the Hotel Roosevelt will be residence headquarters for many, other New Orleans hotels are well worthy of patronage. Page 26 lists them, with their rates. All, including the Roosevelt, are equally distant from the Auditorium—approximately six blocks.

CLOTHING

The weather in New Orleans in October is mild and warm, but not hot. Light weight clothing is recommended.

Ordinary summer attire will be comfortable and appropriate with a light wrap or top coat for cool evenings. Such clothing is suitable for Florida and Havana as well. Delegates who are taking the post-convention trip should bring bathing suits if they want to take advantage of the opportunity to swim at Miami Beach.

RAILROAD RATES

It is expected that winter excursion rates to New Orleans will be in effect as usual after October 1. Since these are less than the convention fares, no identification certificates for Annual Meeting travel will be issued by the Association this year.

Delegates are urged to consult their local ticket agents for the most advantageous round trip fares available from their point of departure.

The rates from various centers to New Orleans are as follows:

RAILROAD RATES FROM VARIOUS CENTERS TO NEW ORLEANS, LA.

	Regular Rate One Way	*Regular Rate Round Trip*	*Special Round Trip*	*One Way Lower Berth*	*One Way Upper Berth*
Atlanta, Ga.	$14.82	$19.80*		$3.75	$3.00

POST-CONVENTION TOUR TO FLORIDA AND CUBA

The Association will sponsor an 8-day, all expense, conducted tour after the Annual Meeting by train, motor, and steamer through Florida to Cuba. The trip will provide enjoyment, interest, and satisfaction in large measure but it is planned definitely for more than pleasure. It may be regarded as an official tour of inspection of Florida and Cuban public health work.

Expenses have been kept to a minimum through the generous hospitality of our hosts in Florida and Havana. Dr. W. A. McPhaul, State Health Officer of Florida, is the Chairman of the Committee on Arrangements in his state. His committee is composed of the health officers and civic authorities of the communities included in the itinerary. Dr. J. R. McEachern of Tampa promises a surprise evening, taking full advantage of that city's unusual entertainment facilities. Orlando is planning a reception, dance, and buffet supper. Dr. George N. MacDonell, Health Officer of Miami, on behalf of Miami and Miami Beach sends a suggestion for a day's activities which even include a dip in the ocean on famous Miami Beach.

Dr. Domingo Ramos, Director of Sanitation, acting for the Cuban Government, proposes the following schedule for the two days in Havana:

October 28, 1936

9:00 A.M.	Inspection Trip. Ministry of Health and Welfare, Finlay Institute, Hospitals and Clinics.
1:00 P.M.	Luncheon. Havana Yacht Club.
3:00 P.M.	Sight-seeing in Marianao and Countryside.

11:00 A.M.	Scientific Session. Hotel Nacional.
1:00 P.M.	Luncheon at National Hotel.
3:00 P.M.	Free for sight-seeing.

This is the barest outline of what the delegate may expect. A detailed itinerary, with costs and travel information, has been mailed to every member of the Association. Though it occupies 24 pages, it still does not include all the things planned for the recreation and education of the post-convention tour group.

Members of the Association, their families and friends are invited to take the trip. *Reservations should be made at once.* Additional copies of the itinerary may be obtained from the Association office.

VITAMINS IN CANNED FOODS

III. VITAMIN A

• The most characteristic evidence of severe human vitamin A deficiency, and one which is increasingly rare in this country, is xerophthalmia. Night-blindness, one of the manifestations that usually precedes xerophthalmia, has been recognized as a deficiency disease since the time of Hippocrates who described the disease, and its cure by eating liver. Infrequent reports of this disorder, however, still appear in the American literature. Most if not all of the symptoms accompanying a deficiency of vitamin A are thought to be the result of an impairment of the epithelial tissue (1). In this connection, a new method for the quantitative determination of this vitamin is based on the keratinization of germinal epithelia (2).

That vitamin A exerts an influence on the growth of human infants and children is also generally accepted.

As early as 1919, a relationship between vitamin A in plant foods and plant pigments was postulated. Research since that date has indicated that beta-carotene and some related compounds may be considered as provitamin A (3).

The vitamin A potency of fruits and vegetables is apparently due to their carotene content, since vitamin A as such has never been found in plant tissue. Ingested carotene is believed to be converted into vitamin A by enzyme action in the liver of the animal (4), in which organ the vitamin is stored.

Vitamin A in the form of carotene may be present in yellow, green or red pigmented fruits and vegetables—in the two latter cases, the yellow color of carotene being masked by other pigments present. Color alone, therefore, is not always a reliable index of potential vitamin A potency.

Both vitamin A and carotene are relatively stable to heat but are subject to destruction by oxidation. However, foods of both animal and plant origin, when canned by modern methods, have been found to retain their vitamin A potencies in high degree (5).

In fact, in some instances, practically no loss of vitamin A potency can be detected by formal bio-assays (6).

Commercially canned foods, therefore, may be used with the knowledge that they will contribute to the American dietary amounts of vitamin A entirely consistent with those contained in the raw materials from which they were prepared.

When you Safeguard Public Health.... you Safeguard the Nation!

BY BETTY LOU WILLIAMSON R.N.

"WITHIN the past three weeks, one of the most prominent urologists in New York saw a practical demonstration of the Nu-Bidet and pronounced it the most advanced forward step in hygiene in the last twenty-five years.

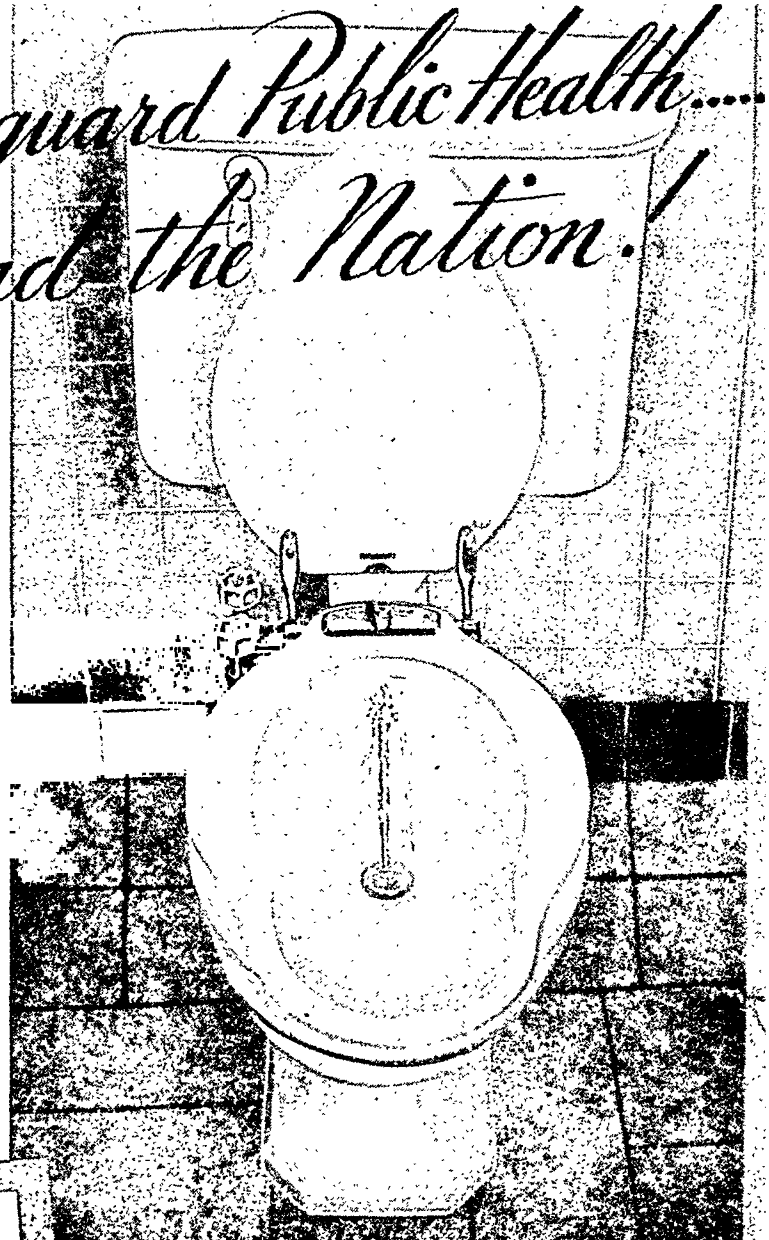
"He is recommending it for installation throughout one of New York's largest hospitals, where he is a member of the board.

"He also said it should be in every home, hospital and public institution in America just from a commonsense hygienic standpoint.

"He recommended that we invite a certain doctor, who is one of New York's outstanding proctologists, to see a demonstration and gave us permission to use his name in contacting him.

"Every physician, specialist and sanitary engineer who has seen the Nu-Bidet has been equally enthusiastic in its praise and has given it unqualified approval.

"You owe it to yourself and to the position you hold to know all about the Nu-Bidet, because to do otherwise would be to stand directly in your own light." Use the coupon now.



The Nu-Bidet is a complete unit of seat, Nu-Bidet and lid in one assembly, which replaces the regular seat and lid, It is equipped with a specially-designed and patented vacuum breaker and also a specially-designed venturi-type siphon breaker, making back siphonage or a cross connection impossible.

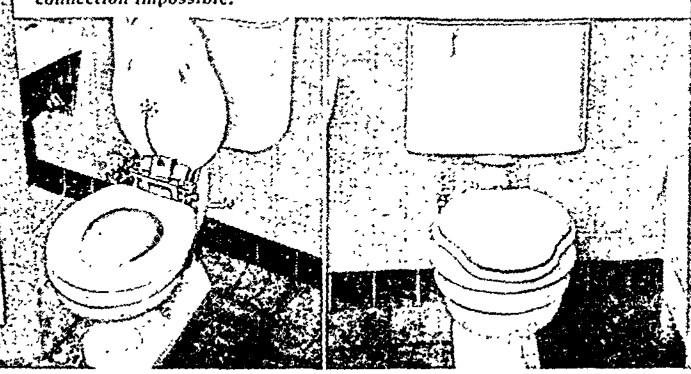
The Nu-Bidet will be in operation and we shall be glad to demonstrate it to you at the Convention of the American Public Health Association at New Orleans, October 20th to 23rd, 1936.

WHAT IS THIS NU-BIDET? READ THIS!

The Nu-Bidet is a thoroughly modernized Sitz Bath...and more. The following uses make it a safeguard to health and as necessary to personal hygiene as your tooth brush or the bathroom itself.

Sitz Bath for personal hygiene and treatment of rectal disorders. Spray for same purpose and feminine hygiene. Attachment for douche, enema and hydrotherapeutics, entirely eliminating the old rubber bag method.

The Nu-Bidet can be installed on any standard-size toilet bowl in less than two hours. It will convert the ordinary bathroom into one that is truly hygienic at a small investment. Use coupon now.



The Nu-Bidet lifts up and stands against the lid when not in use.

The Nu-Bidet looks like the average toilet. No extra space required.

The Nu-Bidet (BEE-DAY)

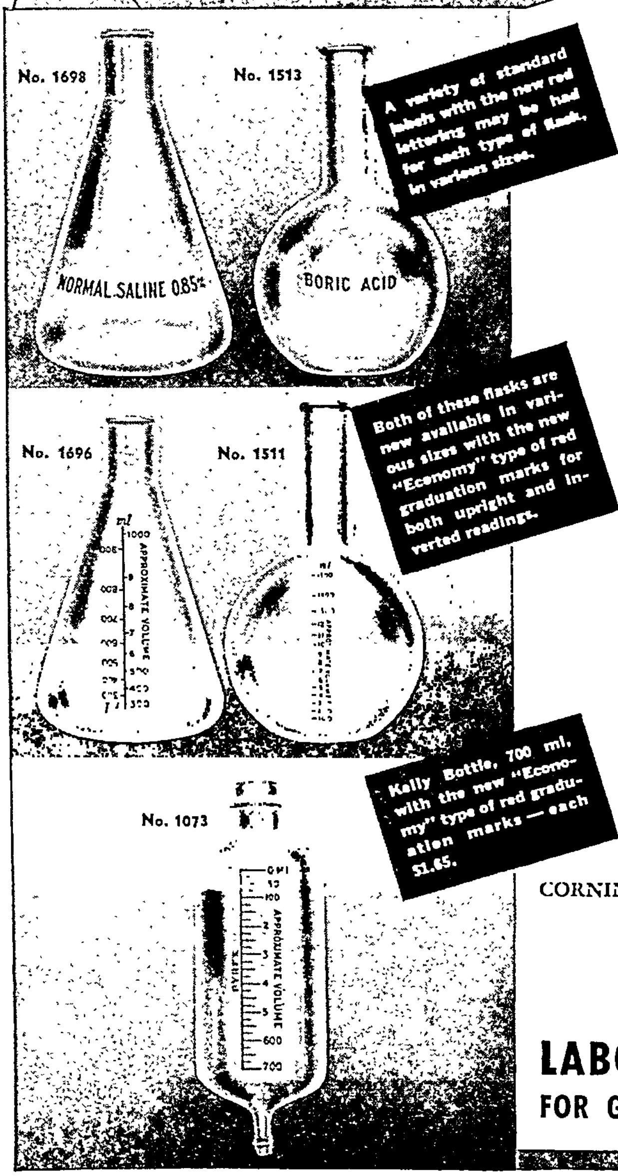
New Markings in PYREX Brand Graduated and Lettered Glassware for Hospital Use



A NEW type of marking for hospital glassware! Permanently legible red markings in a wide variety of labels and graduated scales, at substantial savings over glassware with etched markings.

Clear, red lettering on regular "PYREX" Brand Flasks gives the increased safety of positive identification of solutions for intravenous injection and similar uses. Double scale graduation markings for upright and inverted readings provide for preparing and giving solutions, using only a single container.

This is the same standard "PYREX" Brand Laboratory Ware that you have used for years—rugged, chemically stable, and heat-resistant. Now the items shown are available with this new type of red marking in the outside surface of the glass.

You can get these new "Economy" hospital items from your regular source of supply for "PYREX" Brand Laboratory Ware. For a complete list of the labels and the graduated items available, with sizes and prices, mail this coupon.

NOTE: The volume markings used in this new "Economy" type of red graduations are approximate only.

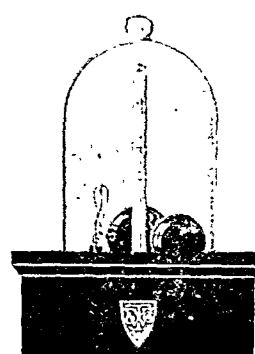
Micrometric accuracy is insisted upon for the control parts of W&T equipment.
A W&T inspector checking a part for a Visible Vacuum Chlorinator

THE CHLORINATION DOLLAR

MUST BUY... ACCURATE CONTROL



TOO LITTLE chlorine in the treatment of water or sewage is useless,—too much, wasteful and unnecessary. To adequately perform its important task, chlorination must be accurately controlled.

Every part of the W&T Visible Vacuum Chlorinator is built to a painstaking standard — every detail of design, calibration and manufacturing is checked and rechecked to insure accuracy over years of service.

Visit a nearby installation. Notice the simplicity, ruggedness and fine workmanship. Note the absence of delicate parts or diaphragm valves — the ease of dismantling for cleaning or adjustment.

You'll no longer wonder why leading engineers and sanitarians everywhere endorse the W&T Visible Vacuum Chlorinator — nor why unfailing accuracy is the record of each installation.

Because of its low maintenance costs, tomorrow's taxpayers will also endorse your choice — if you specify Visible Vacuum Control.

The Sylvatic Plague Committee*

KARL F. MEYER, PH.D., M.D., F.A.P.H.A.

Professor of Bacteriology, Director G. W. Hooper Foundation, University of California, San Francisco, Calif.; Chairman, Sylvatic Plague Committee

AT the sixth annual meeting at Helena, Mont., in July, 1935, the Western Branch of the American Public Health Association authorized the President to appoint a special Committee on Sylvatic Plague. The original appointments of 19 representatives from the States of Oregon, Washington, Nevada, Montana, Wyoming, Idaho, and California, the U. S. Public Health Service, U. S. Forest Service, and U. S. Biological Survey were supplemented by additional representatives to a total of 22. On October 7, 1935, 7 members of the committee, residents in San Francisco or vicinity, held a preliminary meeting to discuss a series of topics and questions which had been submitted to the chairman by the health officers of the western states or their representatives. In order that the members of the committee be informed relative to the purpose and duties, the status of sylvatic plague was outlined as follows:

1. *Historical*—In 1928 R. Jorge, in an exceedingly valuable monograph " Rongeurs et Puce " (Masson et Cie, page 36) summarized the detailed inquiries made by the Office International d'Hygiene Publique. He pointed out that owing to the widespread liability of rodents to *P. pestis* infection, plague not only occurs in epizoötic form among rats but also among wild rodents. Thus two types of epizoötics give rise to correspondingly different human epidemics. The great reservoir among wild rodents (72 species definitely known to suffer from spontaneous plague) slowly invading from colony to colony invariably independent of man's lines of communication and, as a rule, located in deserts or steppe-like countries is epidemiologically rural plague and so different from rat plague that Jorge proposed for this type of epizoötic the designation " peste selvatique " (" Selvatic plague "). In a more recent paper [1], he discusses the subject in detail and uses again the name " Peste selvatique." Although C. O. Stallybrass [2] and Wu Lien-Teh [3] accepted the above spelling, further etymologic inquiries left no doubt that the English word sylvatic in reference to plants or animals means " growing or running wild," and that therefore the correct title " Sylvatic

* Read before the Western Branch, American Public Health Association, at the Seventh Annual Meeting in Vancouver, B. C., June 26, 1936.

Plague," as adopted by the *Journal of the American Medical Association* [4] should be used.

The introduction of this new terminology has not met with unanimous approval by the health officers. Some are of the opinion that plague is plague and from the standpoint of public health it makes little difference whether it is in rats or in wild rodents. In fact, they argue further that it is much better to let the public be made aware of the existence of plague within the boundaries of a county or state. By using a new term, the effectiveness of the mysterious terror creating, fearful unknown which adheres to the word plague, is lost, and the public is lulled into a feeling of perfect safety and financial inertia. Obviously, these arguments cannot influence the investigators. A brief consideration of the facts to be presented leaves no doubt that the type of plague now operating in the United States is different zoölogically and geographically from the plague of the Middle Ages or the "Black Death." It is not the work of rats but of wild rodents; it rages not in the inhabited parts of the country but in the sparsely inhabited or uninhabited, and as an epizoötic which is very poorly understood. By comparison with rat plague which as history has shown rises and falls within a century and finally flickers out, wild rodent-sylvatic plague is everlasting and permanent. With its sequelae so forcibly shown in the Manchurian pneumonic plague outbreaks of 1910–1911 and 1920–1921, and in Oakland, Calif., 1919, sylvatic plague unfolds a number of possibilities and deserves special scientific consideration.

That rodents other than rats may transmit plague to man was first recognized by Reidenko and reported in 1901 [5] but it was reserved for W. B. Wherry, and in particular G. W. McCoy, to prove conclusively in 1908 that the ground squirrel (*Citellus beecheyi*) is not an infrequent source of human plague infection. It is not unlikely that these American studies materially influenced the inquiries which were made into the pneumonic plague catastrophes in Manchuria in 1910–1911. There is no doubt that they guided the carefully planned and brilliantly executed researches of J. A. Mitchell, J. H. H. Pirie and A. Ingram on plague in South Africa. It is painful to note that while English, Russians, Chinese, and South Americans contributed greatly to the elucidation of the sylvatic plague problems in the various foci discovered on 3 continents, American workers, following the departure of McCoy from California, were forced to stand by and devote their energies and inadequate funds to suppressive measures which, in the light of recent developments, are illusory and empirical.

As a guide to future investigations, it is important that the present-day knowledge concerning plague of the wild rodents be made more widely available. This is one of the functions of the Committee on Sylvatic Plague.

2. *Comparative Characteristics of Sylvatic Plague*—It is well known that the pandemic distribution of plague is maintained by a few species of domesticated rats. Sylvatic plague, however, remains localized, since in each region a particular fauna maintains the infective agent. As a rule, one principal species belonging to the family of sciuridae and gerbillinae living in subterranean colonies, in families or singly presides over the exchanges of the plague bacillus, while a group of small rodents (varieties of muridae perhaps jaculidae) act as pestiferous, complementary and intermediate hosts by supporting the epidemicity of the animal plague. The diverse perigrinations of these animals bring the disease agent in the vicinity of human habitations. This complex interplay has received

careful analysis through the time consuming and detailed studies of Nikanoroff in Southeast Russia. The pestigenic rodents are principally herbivorous and the infection, as a rule, is spread by flea carriage. However, carnivorous, cannibalistic habits may greatly favor the spread of the disease leading, as a rule, to a dying down of the epizoötic without providing for its persistence. Concerning the rise and fall (3 to 4 years) or the periodic cycles (10 to 11 years) of sylvatic plague in a given area, Elton (1925) concludes that plague may act as a population regulator which, in its periodic spacings, may be controlled by sun spots, while the short period fluctuations may be influenced by the climate. It remains to be seen whether this theory applies to any one of the principal sylvatic plague foci.

The pestiferous fleas vary according to the species of wild rodents; each group has its own hordes of pulicidae. They disseminate *P. pestis* among the rodents, and when the opportunity arises they attack man with ease. The mechanism of transmission as established by Bacot and Martin for the classical plague fleas has been confirmed by Golov and Joff for the *Ceratophyllus tesquorum* of the suslik.* Contrary to previous experiments showing in South Africa a flea infection carriage for from 3 to 4 months, the observations in Southeastern Russian foci have proved that some of the fleas may carry the infection for 206 days and starve for nearly 196 days. As a rule, these insects attach themselves only while feeding. Since they remain in the nests, it is doubtless difficult to secure a true picture of the ectoparasitic fauna (flea index) by merely counting the fleas found on the wild rodents. Both the fleas captured on the animals and those gathered in the burrows must be counted in order to secure a picture of the vectors to which the rodents are exposed.

The anatomical markings of the rodents involved in sylvatic plague are characterized by lesions in the lymph-nodes and striking tendency to latent infections without gross pathology. Secondary or even primary pulmonary localization is much more common than in the rats. This form of localization may be chronic. Involvements of the lymph-nodes adjacent to the upper and lower gastrointestinal tube as a sequel of cannibalism are by no means infrequent. The diversity of the pathologic lesions in the sylvatic plague animals is no doubt influenced by the variable susceptibility of the rodents during and after hibernation, and possibly the infectiousness of *P. pestis* in the closed lesions. There is always the possibility that human plague due to sylvatic sources is primarily bubonic and septicemic, and may be followed by secondary pulmonary localization (this tendency first clearly recognized in Manchuria has also been stressed by McCoy). The handling of cadavers, furs of the rodents, or direct contact may be responsible for the peculiar involvement of the lung by inhalation. In this respect, the mode and pathway of infection is in part reflected by the laboratory accidents which, as a rule, manifest themselves as plague pneumonias.

3. The renewed interest in sylvatic plague in California and in the western states may be attributed to observations made early in 1934. An increased mortality among the ground squirrels (*Citellus beecheyi*) on the ranches lying north and east of Bakersfield was recognized as plague. Thus for the first time in the history of plague in California, the disease had migrated from the coast counties and, without leaving markings concerning its wanderings, appeared in the foothills of the Sierra Nevadas. It

* Spermophile, or ground squirrel of Northeastern Europe and Northwestern Asia.

is needless to emphasize that the development of these new foci despite well organized suppressive measures created justifiable concern. The many discussions incident to these unforeseen developments acquainted the Agricultural Commissioners, the U. S. Forestry Service, and the Biological Service with the problems involved. Representatives of these agencies engaged in the distribution of poison on government lands in Modoc County (Northeastern County of California) observed dying and dead squirrels on ranches north and east of Alturas.

Surveys made during the summer proved plague in 5.1 per cent of the shot or dead Oregon ground squirrels (*Citellus oregonus* [Merriam]) collected in an area of 65,000 acres. Inquiries disclosed the interesting fact that at periodic intervals over many years, epidemics have appeared among the squirrels of Modoc County. Since tularemia is by no means uncommon in this particular part of California, it was quite generally believed that the rodent epizoötics were caused by *Bacterium tularense.* Shortly after the discovery of sylvatic plague in Northern California, reports were received relative to the bacteriological confirmation of a case of human plague at Lakeview, Ore. (May 16, 1934). The history of this case as presented by William Levin [6] is as follows:

C. S., aged 30, sheepherder, was employed on a desert near Lakeview. There were a number of tick bites on his right ankle, which (probably?) were the source of his infection. The onset of the symptoms was on May 19; the temperature was 105°, pulse 110, leukocytes 14,000. There was tenderness and a swelling in the right groin the size of an egg. There was slight improvement the next day. On the following day the patient felt strange; there was noticed a dusky livid hue over his body. This became more pronounced and death occurred on May 21 from an overwhelming toxemia. The patient was very dark at death.

Extensive surveys clearly showed that the Southern Oregonian focus responsible for the infection in the sheepherder was connected with the California areas, and that the invasion occurred from the north and is in no way connected with the principal areas south of the Sacramento River.

Aside from the fatal human case of plague in Oregon, a very interesting observation was made in California. In June, 1934, a 10 year old school boy from Porterville visited a ranch on which plague infected squirrels had been found, and contracted bubonic plague (right axillary bubo). He recovered from his local process, but died on the 125th day after the onset of his illness from chronic plague meningitis. This observation proves the occurrence of chronic latent plague in man.

In April, 1935, shortly after the first squirrels emerged from hibernation, the survey activities were renewed in Modoc County. New areas were recognized. Plague was proved in 107 Oregon squirrels (7.1 per cent, 1,492 shot squirrels), 4 wood rats (*Neotoma*) and 1 white footed field mouse (*Peromyscus*). Ranchers also reported squirrel mortality on the valley meadows of Northern Lassen County which orographically connects the sylvatic plague foci of Modoc County. An examination of 198 squirrels yielded 1.5 per cent infected with *P. pestis.* In the course of these investigations, latent, inapparent plague was discovered by guinea pig inoculations of lymph-nodes removed from Oregon squirrels with no gross anatomical markings of disease.

Simultaneously, the U. S. Public Health Service proved plague infection in the Oregon and Columbia squirrels found dead or shot in Lake, Grant, and Wallowa Counties, Ore. Of greatest concern and importance was doubtless the demonstration of plague in a ground squirrel (*Citellus richardsonii*) near

Dillon, Beaverhead County, Mont. Despite the extensive reservoir of diseased rodents, no human cases were reported during the year 1935.

In this connection, it appears advisable to place on record the observations made in 1936 to date, June, 1936, although this information was obviously not presented to the committee in October, 1935.

During March, 1936, the Agricultural Commissioner of Ventura County accidentally noted a sick *Citellus beecheyi* which on autopsy presented the lesions of subacute plague. The rodent was found adjacent to an old sylvatic plague focus. Far more alarming is the recognition of a case of pestis minor (left axillary lymph-node) in a veterinarian who practised in Sonoma County, north of San Francisco Bay. Despite detailed investigations, the source of this infection has not as yet been established. Equally significant is the demonstration of plague infected fleas collected from *Citellus armatus* in Elko County, Nevada, by Dr. C. R. Eskey of the U. S. Public Health Service in May, 1936. Several hundred squirrels had been examined for plague in this region but none had been found with suspicious lesions.

The new procedure to locate plague infection among squirrels by collecting the fleas present on the rodents and by injecting an emulsion of the insects into guinea pigs was originally suggested by Dr. Eskey to the committee. The method is exceedingly promising since the Hooper Foundation has succeeded equally in demonstrating plague infected fleas in Ventura County in the Fandango Valley, the Modoc National Forest, and Pine Creek (Modoc County). In the 4 instances, the insects had been collected from rodents without suspicious plague lesions. Active sylvatic plague had not been observed in Fandango Valley since the fall of 1934. Quite recently septicemic and localizing subacute plague has again been proved in the squirrels of Northern Lassen County and new areas in Modoc and Santa Cruz Counties. A second case of pestis minor in an 11 year old boy has been diagnosed in the southern sector of Monterey County.

Dr. C. R. Eskey has demonstrated *P. pestis* in fleas and squirrels (*Citellus armatus*) forwarded by the U. S. Public Health Service and the State of Idaho mobile laboratories, on two ranches in Bonneville County, Ida. A case of human plague has been recognized in Southwestern Utah.

Following the presentation of the facts, the group discussed and answered a number of questions which had been submitted for consideration by the committee. Since these deliberations brought to light several pertinent points of general interest, it is deemed advisable to detail the questions and answers.

(a) *What is the scope of the work done or expected to be done by the federal agencies in connection with sylvatic plague?*

The U. S. Public Health Service has been directing its efforts and will continue to determine the presence of plague infection in field rodents in the 8 western states, with more limited application to California due to the extensive survey activities conducted by the State Department of Public Health.

Under the guidance of Dr. C. R. Eskey, the plague laboratory at San Francisco will make field surveys, and examine specimens of rodents received from county agents, state veterinarians, and other officials. Incidental to the determination of sylvatic plague areas, special studies relative to the insect vectors and ectoparasites will be carried out. It is intended that monthly reports of the number of rodents examined will be submitted to the state health officers. Special reports will be forwarded immediately in the event of

plague infected rodents being found and recognized.

The U. S. Biological Survey will coöperate with the Agricultural Regulatory and Service Agencies in the educational and control work in the several states and, in the case of the federally owned and controlled lands, it will operate directly in coöperation with the U. S. Forest Service. The U. S. Forest Service, wherever its interests are involved, will seek the assistance of the U. S. Biological Survey in an effort to eliminate diseased rodents from the National Forest areas.

(b) *What should be expected of the state health departments in the control of sylvatic plague?*

It is fully recognized that each state must ultimately recognize and appreciate its own responsibility with respect to sylvatic plague in the field rodent population, and should make every effort to coöperate with the federal agencies to determine the extent and distribution of the disease. In particular, it is desirable that provisions be made for a state laboratory to care for the determinations of plague within its jurisdiction. It is generally agreed that the control work should be centralized with the established agencies entrusted with rodent suppressive measures. In all of the western states, with the exception of California, rodent control is carried out in coöperation with the U. S. Biological Survey. In a number of the states, the allotments for control are directed to the Biological Survey, while in others a local agency supported by state funds operates in close coöperation with the Biological Survey. However, it is recalled that the activities of the Biological Survey are limited by the federal funds allotted, although it stands ready to coöperate with any existing agency or any agency which may be established.

In California the following system of coöperation has been developed: The State Department of Public Health, through its 5 survey crews, determines the location of the sylvatic plague foci and reports them to the Agricultural Regulatory Agencies consisting of the State Department of Agriculture and the County Agricultural Commissioners. The State Legislature makes direct allocation of funds to the State Department of Agriculture for rodent elimination on plague areas. These funds are utilized on a three-way coöperative basis whereby the state, county, and land owner participate. This arrangement insures an equitable distribution of the burden of the costs, and impresses the land owner with the benefits derived from ground squirrel and rodent elimination on his property.

(c) *Should the activities in any state be concentrated in one department, such as the state health department? or should they be divided among several departments, such as the departments of health or agriculture, sanitary live stock department, veterinary department, extension service, etc.?*

In the event sylvatic plague has been demonstrated within the boundaries of a state, it is imperative that a committee, called by the state health officers, define the duties of the various agencies temporarily enthusiastic in participating in the control of a newly discovered disease. Experience has shown that the health department in coöperation with the U. S. Public Health Service is best qualified to determine and diagnose the existence of plague. In turn, the department reports to the properly constituted agencies, either a special commission, the Extension Service, the U. S. Biological Survey of any other agency.

When plague has been found, the control of the disease in its various ramifications is a joint responsibility of the state and federal governments. However, it is fully recognized that the state in whose boundaries sylvatic plague has

been proved will assume responsibility and participate to the fullest extent by furnishing funds both for disease detection and control. Each state should have its own plague laboratory, properly equipped and staffed with trained personnel. Furthermore, it will be necessary to provide definite standards for systematic follow-up work, and intra- and interstate reporting not only of the sylvatic foci discovered but also with respect to the results secured in the course of the suppressive measures.

It is generally recognized that the agencies entrusted with the control of the economic damage directly attributable to rodent pests must concentrate their efforts on the elimination of diseased rodents and their vectors immediately following the recognition of plague. This principle assumes the position of primary and major importance, and every other activity must be subordinated and coördinated with the plague program.

In addition to the discussion of the above questions, the group considered the methods which may be used to obtain information concerning the location of sick, dying, or dead rodents; procedures of shipping specimens suspected of plague; publicity; institutional course on sylvatic plague in San Francisco; appointment of an executive committee; and future meetings. The committee was circularized with a questionnaire relative to the items mentioned.

INSTRUCTIONAL SHORT COURSE ON SYLVATIC PLAGUE

Under the auspices of the committee, an instructional short course was held at San Francisco and vicinity. On April 27 and 28, 1936, lectures and demonstrations were given in the laboratories and lecture rooms of the Department of Medical Bacteriology, University of California, Medical Center, and the U. S. Public Health Service Plague Laboratory, Marine Hospital, San Francisco. There were in attendance 125 representatives from Idaho, Montana, Oregon, Washington, and California. Those present were furnished a detailed mimeographed syllabus of the lecture and laboratory demonstrations.

Splendid demonstrations concerning the equipment and technic employed in the field study of plague were given by E. T. Ross, Chief Sanitary Inspector, California State Department of Public Health and his staff near Brentwood, Contra Costa County, on April 29, 1936. Similarly, on April 30, 1936, E. E. Horn and staff members of the U. S. Biological Survey and California State Department of Agriculture gave field instruction in the methods used in rodent control.

Careful planning assured a perfect organization and an uneventful execution of the unique program which was greatly appreciated by everyone in attendance. Judging from reports received, the course must be considered the major contribution of the committee to the organization of an effective control program against sylvatic plague in the western states. Plans are being made to repeat this type of instruction when needed.

During the short course, the chairman called a general meeting. He outlined the long view of the problem and sketched the duties of the committee as follows:

1. To act as an open forum for the discussion of all phases of the problem connected with sylvatic plague research and suppressive measures.
2. To coördinate the studies and control activities in the western states.
3. To advise and guide the publicity and educational program.
4. To organize instructional facilities, and to provide scientific aid in connection with the identification of rodent diseases and insect vectors.
5. To inform at frequent intervals the official agencies of the states concerning the trends of sylvatic plague.

6. To aid the agencies involved in plague work in securing adequate funds for the maintenance of laboratory and field investigative facilities as well as proper rodent control measures.

Dr. R. R. Parker, Director of the Rocky Mountain Laboratory, U. S. Public Health Service, at Hamilton, Mont., presented a carefully prepared and exhaustive research program on sylvatic plague embodying 15 major points. The headings are herewith recorded in order to indicate the broad scope of the investigative field involved.

1. Study of fleas of the native fauna
2. Studies of other parasites of the native fauna
3. Study of the native fauna (identification and ecology of species)
4. Ecology of the burrows and nests of the native fauna (during active season and during estivation and hibernation)
5. Susceptibility to plague of the native fauna (particularly rodents at first)
6. Laboratory study of the disease in susceptible native animals (course, types of disease and immunity)
7. Flea culture
8. Determination of what species of native fleas are active or are capable of acting as transmitting agents of plague
9. Determination of whether any parasites other than fleas are acting or are capable of acting as plague transmitting agents, or as agents in the natural maintenance and perpetuation of the disease
10. Natural occurrence of plague in the native fauna and fleas (tests for inapparent infection, occurrence of immune animals of susceptible species and their significance)
11. Study of how sylvatic plague survives the winter
12. Study of means by which plague is spread
13. How plague is maintained in nature
14. Study of diseases of small animals other than plague and particularly those that simulate plague (The Hooper Foundation will act as the clearing center for problems of this sort.)
15. Observations relating to direct and indirect opportunities for contact between susceptible species of the native fauna and man

The committee fully appreciates that the effective suppressive measures can be planned only when the scientific investigations have furnished the answers to the many unknown factors doubtless operating on a large scale. Obviously, a research program of the scope outlined must by necessity be divided among many properly qualified workers. Field investigations are increasingly more important than laboratory studies. The University of California group has perfected plans to study certain phases grouped under 1, 4, 5, 6, and 11.

Following the presentation of the report by Dr. Parker, the committee discussed in detail a number of important subjects, and by resolution adopted the following recommendations:

(A) The Sylvatic Plague Committee, desirous of the coöperation of Dr. M. A. Stewart, Assistant Professor of Entomology, University of California Branch at Davis, requested the chairman to communicate with Professor C. B. Hutchison, Dean of the College of Agriculture, in order to secure permission for the establishment of a central authority urgently needed for the identification of fleas collected from rodents. (This permission has been granted; Professor Stewart has accepted the invitation; and a circular detailing the methods to collect and ship fleas to the Central Flea Laboratory has been mailed to the members of the committee.)

(B) The Sylvatic Plague Committee will communicate with the state universities, colleges, and museums throughout the western states to devote attention to the investigations, and to record the distribution and ranges of rodent groups, birds, and mammals which may be incriminated or suspected of serving as carriers of diseases transmissible to man.

(C) By authority of the committee, the chairman was delegated to invite the U. S. Bureau of Biological Survey to place at the disposal of the members such data and information from their faunal studies, both complete and incomplete, as may be needed in the elucidation of certain phases of sylvatic plague.

(D) The committee authorized a well worded communication calling the attention of the officials in the western states to the proper function to be performed by the states and the financial needs relative thereto in respect to sylvatic plague; the communication to outline the relationships of the state hy-

gienic laboratories to the plague investigations now in progress.

(E) The committee endorses the proposal to address a circular letter to the directors of agricultural extensions and the directors of the several departments of agriculture in the western states requesting that the committee be advised relative to forthcoming meetings of county agents and farmers in order that representatives of the Plague Committee may be present to discuss the problems involved and to solicit coöperation in reporting epidemics among rodents. (The chairman has addressed a group of representatives from the various departments at Salt Lake City, Utah, May 16, 1936, at Seattle, June 29, and Portland, June 30, 1936.)

The chairman of the committee, in submitting the report and the resolutions to the Western Branch of the American Public Health Association for its approval, recommends the reappointment of the membership, executive committee and continuation of the entire committee as constituted.

Plague Infection Discovered in Fleas and Lice Taken from Marmots in Montana and in a Marmot in Utah

A REPORT has been received, under date of August 10, 1936, from Surgeon C. R. Eskey, in charge of plague suppressive measures, San Francisco, Calif., that plague infection had been discovered in fleas and lice taken from ground hogs (marmots) which had been killed in Small Horn Canyon, Mont., about 12 miles southwest of Dillon, Beaverhead County. Following is Surgeon Eskey's report:

Plague has been determined in both fleas and lice taken from 7 ground hogs (marmots) shot at the head of Small Horn Canyon, about 12 miles southwest of Dillon, Beaverhead County, Mont., July 25, 1936, by employees of the Rocky Mountain Laboratory. One hundred and fifty-three fleas and 26 lice were collected in separate bottles and inoculated into guinea pigs, which died in 6 and 3 days, respectively. Secondary inoculations and cultures gave typical plague reactions.

These findings are of interest because they provide the first direct evidence that plague exists among marmots in America and demonstrate that the infection may be recovered from lice as well as fleas taken from these rodents. Fatal epizoötics have been noted among marmots in a number of localities in western states, but no infected animal has yet been found.

The foregoing report has been supplemented by later information (dated August 13) received from Surgeon Eskey in which he states that plague has been determined in a sick ground hog (marmot) killed July 31, 1936, in Indian Creek Canyon, 14 miles northeast of Beaver, Beaver County, Utah. This is believed to be the first plague infected marmot reported in the United States.—*Pub. Health Rep.* 51, 34:1059 (Aug. 21), 1936.

A Study of the Pollution of a Shellfish Producing Area*

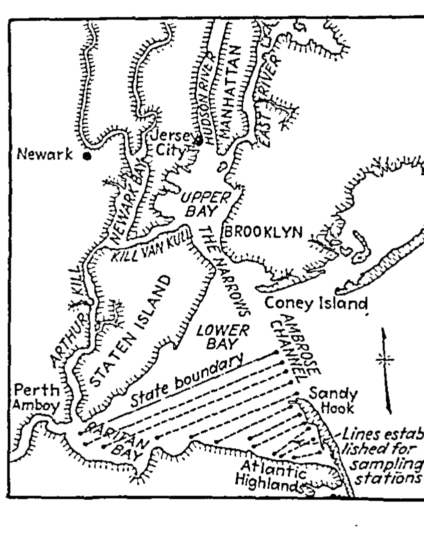
ARTHUR P. MILLER, C.E., F.A.P.H.A. (*Life Member*)
Sanitary Engineer, U. S. Public Health Service, New York, N. Y.

FOR many years Raritan Bay † has been a prolific producer of both hard and soft clams. Whether this variety of shellfish was harvested from this area years ago to the detriment of the public health I cannot now say but with our present knowledge concerning the relationship between contaminated shellfish and the incidence of certain diseases, it behooves present-day public health agencies to consider more carefully the sources of market shellfish.

EXISTING RESTRICTIONS

The health authorities of New York City recognized the danger in taking clams from the polluted waters of this large area as early as December, 1924, when they closed their markets to all shellfish from them except string clams marked " For cooking purposes only." New York State officials closed the New York portion of the bay for the taking of shellfish for marketing purposes in 1925, and in 1934 the New Jersey State Board of Health took similar action on certain shoreline areas, thereby restricting the taking of clams to those sections which in their opinion were satisfactory. All of these official actions reduced the clamming grounds in the bay to an area much smaller than was formerly available. This area is a good clam growing one which can support a large number of shellfishermen. In Highlands, New Jersey, the taking, shucking and packing of clams is one of the important industries today and the livelihood of many families is dependent upon activities incident to it. There is no inclination on the part of any public health officer whom I know to insist upon the closure or restriction of any shellfish area which does not merit such action. However, if there is any doubt concerning the quality of

RARITAN BAY IN RELATION TO OTHER PARTS OF THE NEW YORK METROPOLITAN DISTRICT AND THE AREA IN WHICH SAMPLING LINES WERE ESTABLISHED



* Presented at the Annual Meeting of the New Jersey Sewage Works Association at Trenton, N. J., March 19, 1935.

† Raritan Bay, as used in this paper, will be considered as those areas shown on U. S. Coast & Geodetic chart #369 as Raritan Bay, Sandy Hook Bay and Lower Bay.

an area, a decision must be made against the area and in favor of the public health. The only tenable position—one with which the shellfish industry as a whole will agree, I am sure—is that no chance should be taken when disease, suffering, and possibly the loss of lives are in one balance with the need for limiting or restricting a local industry in the other.

It was, apparently, with these considerations in mind that New York City through its Board of Health erected a barrier against clams from this bay by prohibiting their sale in that city. Inability to sell to New York City dealers presented a severe handicap to the shellfish industry along the New Jersey shore of Raritan Bay and warranted relief measures if they could be secured safely. This was the situation in the summer of 1935 when the desirability of this survey was first mentioned. After several conferences by the interested groups, New York City agreed to permit the sale of clams within city limits from those areas in Raritan Bay, N. J., found by the U. S. Public Health Service to be suitable for clam harvesting. Having secured such a fair decision, it remained only to ascertain by careful study what sections—if any—of these New Jersey waters were suitable for the removal of clams for direct sale to dealers.

FACTORS INCLUDED IN STUDY

The *Report of the Committee on Sanitary Control of the Shellfish Industry in the United States* drawn up and published in 1925 set forth a number of specific recommendations concerning the scope and enforcement of state regulations for the sanitary control of shellfish. One of the essential requirements was stated to be "that no shellfish should be offered for sale except such as have been taken from beds which, after careful and competent examination, are found to be free from any justifiable suspicion of contamination which is judged to be either dangerous or offensive." In discussing the provisions essential to fulfilling this requirement, the committee outlined briefly how and under what conditions an area should be approved. Its stipulations were as follows:

> . . . that before approval is given for the use of any area for the taking of oysters for market, the area should be carefully examined by competent and responsible officials.
>
> The examination of the area should always include a sanitary survey, which should be supplemented by bacteriological examinations of the water and shellfish wherever these may be necessary for competent judgment. Since it is essential that the examinations be made and interpreted only by persons having the necessary qualifications of technical education and experience, it is assumed that the purposes, methods, and limitations of sanitary surveys and bacteriological examinations will be understood and need be outlined only briefly here.
>
> The primary purpose of the sanitary survey is to estimate as accurately as possible the extent of actual or potential contamination of the waters in question with *human excreta*. A distinction must be made between such pollution and that from animal sources or from the soil, as a necessary basis for the interpretation of the results of bacteriological examinations.
>
> The survey should, therefore, take careful account of all the determinable factors affecting pollution; namely, the sources of actual or potential fecal contamination, with special reference to human excreta, considered in relation to methods and efficacy of artificial treatment of sewage and to the natural safeguards afforded by dilution in the receiving body of water and by natural purification, as influenced by temperature and by time intervals between contaminating sources and the shellfish beds, due regard being paid to the likelihood of contamination in coves and inlets from sources which would be insignificant in relation to a large and well mixed body of water. Careful consideration should also be given to the likelihood of dangerous contamination from boats, especially in small and shallow bodies of water and in the vicinity of main ship channels. Any discharge of excreta from oyster boats in the vicinity of shellfish beds should be rigidly prohibited.
>
> Although the information furnished by a survey of this kind is not exact in a quanti-

tative sense, it will be sufficient for forming a reliable judgment when the examination shows such pollution or risk of pollution as to render the area obviously unfit, or conversely, where it shows that there is no discoverable probability of dangerous contamination. Where the survey shows exposure to more or less constant but probably slight pollution with sewage from rather distant sources, or with surface drainage from populous unsewered territory, so that the safety of the area depends upon the protection afforded by dilution and natural purification, there is need of more exact quantitative information than is furnished by a sanitary inspection alone; and in such cases bacteriological examinations of the waters and shellfish are a necessary part of the study.

Undertaking an inspection such as outlined above consequently involved a study by competent personnel of actual and potential sources of contamination; the results to be summarized in a quantitative way and considered in relation to dilution, tides, currents, and time intervals. Such a study necessarily entailed the collection of both physical and bacteriological data.

In my elaboration of this particular study, I will discuss (a) the quantities of sewage reaching Raritan Bay and their probable effect on the New Jersey waters thereof; (b) the influence of natural factors such as winds and tidal currents; and (c) the bacteriological confirmation of tentative decisions reached from the examination of the physical data.

QUANTITIES OF SEWAGE DISCHARGED

Through the coöperation of the Department of Sanitation, City of New York, and the State Department of Health of New Jersey, I have been able to secure approximate figures on the quantities of sewage reaching Raritan Bay either directly or by way of tributary streams. In Table I these data are tabulated divided in two different ways; namely, on the basis of (1) treatment and (2) the receiving body of water. Obviously, these figures include only the discharges from territory lying within a reasonable distance of Raritan Bay.

In New York, treatment as shown in this table consists of fine screens with or without chlorination. In New Jersey, it involves combinations of the processes of sedimentation, oxidation, and chlorination, and in most cases is of higher character than treatment at any New York State outlet includes.

AVAILABLE DILUTING WATER

In the following discussion of available dilution, the treated and incompletely treated wastes will be ignored and only untreated sewage considered. The greatest volume of raw sewage finding its way into the bay through contributory streams comes from New York State and is approximately 858 m.g.d. With the exception of possibly 14 m.g.d. most of this large amount or 844 m.g.d. passes into the bay through the Narrows. This seems to be a tremendous volume but when it is compared with the entire flow of water through this section it is not so imposing. In the *Report of the Metropolitan Sewerage Commission of New York* (1914), a U. S. Coast and Geodetic Survey letter describes a discharge at the Narrows of 105,000 m.g.d. at ebb tide, and 97,500 m.g.d. at flood tide, averaging 101,250 m.g.d. The flow of sewage at this point is, therefore, about 0.84 per cent of the diluting water there. In other terms, there are 119 gallons of diluting water for each gallon of sewage.

There are approximately 55 and 25 m.g.d. of sewage coming from Arthur Kill (plus Newark Bay) and the Raritan River respectively. Although precise figures on the flow of water in these two tributaries are not available, both of them are relatively large with 25' to 40' channels, and unquestionably have sufficient quantities of water issuing from them to give a dilution factor

higher than that for the Narrows. The contribution to the bay from the Shrewsbury River (0.1 m.g.d.) is too small as compared to these others to warrant further consideration of it. It should be kept in mind, also, that a large proportion of the sewage heretofore mentioned enters the contributing

streams at varying distances from Raritan Bay and has received partial natural treatment (dilution and oxidation) before passing into the bay.

Let us now examine the amounts of sewage entering the bay directly—because of proximity—a far more important question in so far as shellfish growing areas are concerned. From New Jersey there is no direct flow of raw sewage into the Bay. From New York there is about 1.1 m.g.d. of untreated sewage entering Princess Bay, a small arm of Raritan Bay and 44 m.g.d. Sheepshead Bay. Exactly speaking, this last discharge is not directly into Raritan Bay being at a point some distance toward the sea from a line drawn between Norton Point on Coney Island to Sandy Hook. However, as these wastes ebb and flood out of and into the bay they are brought into the discussion.

Summing up the question of raw sewage contributions, we find fairly adequate dilution available for those wastes not directly deposited in the bay; 1.1 m.g.d. discharged immediately into the bay on the New York side; and 44 m.g.d. deposited at a point on the same side sufficiently close to bay waters to have an effect on them because of tidal currents. Although this bay occupies an unfortunate position for shellfish cultivation on account of the metropolitan character of the surrounding territory, the great volume of water in it seems to afford fair protection to certain selected areas. If only a small portion of these wastes were in direct contact with the shellfish areas under consideration there would have been little purpose in this study, but dilution and other factors to be discussed force one to entertain more favorable conclusions regarding their quality.

EFFECT OF CHANNELS

As I have pointed out, the greater volume of sewage entering Raritan Bay does so through the Narrows although smaller amounts also come in from Arthur Kill and the Raritan River. Without considering certain physical factors, one might assume that all of these wastes would mix thoroughly with the entire mass of bay water. There is, without doubt, some intermingling at the edges of the flow coming through the Narrows from Upper Bay but on the whole it follows a fairly well defined path. The same is true of the discharge from Arthur Kill but not so much of that from Raritan River which tends to mix more completely with the waters in the western end of the bay.

In my opinion the two principal forces controlling these wastes and working to keep them out of New Jersey waters are the channels and the tidal currents. The Upper Harbor flows carrying the bulk of New York City's sewage tend to move out to sea through Ambrose Channel while those from Arthur Kill seem to follow the 30' channel running from the tip of Staten Island up into Princess Bay and from Seguine Point in that bay toward Sandy Hook. This tendency was observed on the waters during our traverses of the lines of sampling points and could be recognized through the movements of floating debris.

TIDAL CURRENTS

The evidence on the directions of flow secured through a study of the tidal currents in these waters is more compelling. *Special Publication # 152* of the U. S. Coast and Geodetic Survey entitled "Tidal Current Charts—New York Harbor" gives 24 charts, each of which shows the direction and velocity of the tidal currents for its specific tidal hour at Governors Island, N. Y. The following descriptions are of those charts which produce the most proof to assist this study:

1. At low water—Southern Raritan Bay water and that within Sandy Hook is moving

to sea. Upper Bay water is, in the main, moving to sea although there is a slight tendency for it to encroach on the New York side of Raritan Bay.

2. At 1 hour after low water—Sea water is moving in, pushing the Upper Bay flow over onto the New York side of Raritan Bay to such an extent that there is a current created flowing directly from the Upper Bay across Raritan Bay in New York, around the southern end of Staten Island and up Arthur Kill to a slack point located just north of Staten Island's southern tip.

3. At 2 hours after low water—The currents at this time are much the same as described for 1 hour after low water except that the sea water has reached a point farther in Raritan Bay and slack water in Arthur Kill is up to the northwest tip of Staten Island.

4. At 3 hours after low water—The incoming tide has now reached such proportions that it cuts off the flow from Upper Bay not permitting it to cross Raritan Bay.

A normal tidal current flow is represented by the chart for 2 hours after high water, a description of which is as follows:

The flow from the Upper Bay is moving down and out toward the sea at a distance from Coney Island of about half the opening between Coney Island and Sandy Hook, while the flow from Arthur Kill is moving across Raritan Bay, confined right definitely to the northern half, on by Sandy Hook and out to sea.

What can be deduced from this information? First, that depending upon the tide, the sewage coming through the Narrows either flows smoothly out to sea with only its edges intermingling with clean water or is pushed back toward the New York shore to such an extent that it flows westward over Raritan Bay and up Arthur Kill, and second, that the flow from Arthur Kill and to some extent from Raritan River on the flood tide goes northeast into Princess Bay and then directly across Raritan Bay on the New York side and out to sea. Probably more than anything else, these tidal currents help to restrict the New York wastes to New York waters thereby protecting the waters of the New Jersey portion of Raritan Bay.

Reverting now to my summation of the quantities of raw sewage entering directly into the Bay, let us consider them in conjunction with the tidal currents. At Princess Bay, 1.1 m.g.d. is discharged directly. This small volume must be caught up in the tidal current moving from the mouth of Arthur Kill up into Princess Bay and then off toward Sandy Hook. This quantity combined with what comes out of Arthur Kill and Raritan Bay seriously affects the New York side of the bay but does not seem to spread to such an extent as to reach the bulk of the New Jersey waters. The 44 m.g.d. deposited in the vicinity of Sheepshead Bay is flooded back up through the Narrows or toward Staten Island and then ebbed out to sea. Some of it probably works over toward Princess Bay and to a minor extent in toward Sandy Hook after several ebbs and floods of the tide.

FLOAT STUDIES

The 1914 report of the Metropolitan Sewerage Commission includes a number of charts of float studies made in New York Harbor and adjacent waters. Only one chart of the group showing floats started at various points in the Upper Harbor or outside of Sandy Hook gave evidence that New York sewage might approach as close to the New Jersey side of the bay as Romer Shoal light. All others supported the theory that but little of the sewage discharged through the Narrows or along Coney Island reaches New Jersey waters in any appreciable amount.

WINDS

Tidal currents when undisturbed by other influences may be presumed to remain fairly consistent in their movements, but strong winds have been known to deflect large quantities of

water from their normal paths. What then is the history of winds in this area? For the 10 year period 1925-1935, the Weather Bureau reports that northwest winds prevailed in this vicinity during the shellfish season (September-April). For the 20 year period, 1915–1935, the average velocity of the winds was 15.2 m.p.h. which is equivalent to a moderate breeze. From the viewpoint of sewage polluted waters being pushed over from the New York side on to New Jersey shellfish areas, we have, therefore, winds from about the most favorable direction. However, the average velocity is so low that the results of this force are not disastrous although there is, without question, some measurable deleterious effect.

Having carefully examined the natural or physical factors, a survey of this kind next requires confirmatory evidence obtainable through bacteriological examinations of water samples from the area under inspection.

PLAN AND PROCEDURE IN WATER SAMPLING

Lines of sampling stations between fixed shore points are most desirable, but in a body of water such as this, such lines cannot always be had. Therefore, it was necessary, on the 5 outer lines which vary in length from 13,000 to 24,000 yards (7½ to 13½ miles), to run by compass and watch, using a boat, the speed of which had been calibrated in advance. The other 6 lines of sampling points were from fixed objects on shore which could be sighted from a moving boat. In addition, there were a few odd stations identified by objects in the water. Altogether 118 sampling stations were selected and all of them were used. Aside from days of severe weather, the sampling routine encountered no difficulties, and on our first regular run of 24,000 yards we checked on a fixed object located at the 22,000 yard point with an error of 100 yards.

The New Jersey State Department of Health conducted most of the sampling work although the writer and his assistant were present on several occasions. Sampling equipment was very simple consisting only of sterile 10 c.c. tubes plugged with cotton and a short stick on the bottom of which was a spring device to hold the tubes in position when forced into the water. The boat's speed, the watch, and the chart of stations were checked constantly by one man who was responsible for the sampling. A pilot operated the boat and a third man took the samples when so ordered. Only top water samples were taken.

From May 20 to June 22, 1935, when this work was done, 5 complete runs were made of the entire series of stations. Starting times were calculated each day to insure in the end 5 samples at each station for the following tidal conditions: (1) High tide, (2) Low tide, (3) Half flood tide, (4) Half ebb tide, (5) ¾ ebb tide. By following this scheme rather than just taking samples at times most convenient to the workers, we had at the end of the survey results which were exactly comparable. In other words, the tide intervals between samples at any one station were exactly the same as the tide intervals for samples at any other station. In so far as I know, this is the only method by which one can secure samples at the same tide intervals when a long series of stations must be covered.

BACTERIOLOGICAL LABORATORY AND PROCEDURE

A laboratory was established by the New Jersey State Department of Health at Highlands, N. J., and all samples were examined the same day they were collected by personnel of that department with a laboratory aide from the

writer's station coöperating. Media and other supplies were brought from that department's central laboratory in Trenton as needed. *Standard Methods of Water Analysis* was followed for the determination of *B. coli.* We did not plant 5 tubes of each dilution for each sample as is sometimes done in surveys of this kind. This procedure entails too much work for a field laboratory and we could have done it only at a sacrifice in volume of work. Hence, in the main, 1-10 c.c., 1-1 c.c., and 1-0.1 c.c. amounts were planted for each sample. As the interpretations were to be drawn on the basis of 1.0 c.c. tube results using those of the 10 c.c. and the 0.1 c.c. tubes as guides, this method was satisfactory.

BACTERIOLOGICAL RESULTS AND THEIR INTERPRETATION

It was also shown for each sampling station the percentage of 1 c.c. tubes positive for *B. coli.* These are the critical values which are used to supplement the conclusions reached by an examination of all other information. In this case, high results were found in the far western end of the bay and in that portion between Sandy Hook Point and Romer Shoal light, and to the northwest of Sandy Hook Point. Except for isolated cases, the bacteriological results in the remainder of the bay were quite satisfactory.

In recent years there has been considerable discussion among those engaged in sanitation activities related to shellfish as to what shall constitute a clean area for growing purposes. The *Report of the Committee on the Sanitary Control of Shellfish in the United States* in its supplementary report of 1927 treats this subject as follows:

> As to what constitutes satisfactory evidence that an area is fully protected against contamination with disease producing microorganisms, judgment in any given case should be based upon all the facts available, considering different observations not separately but in their relation to each other. Thus, the correct interpretation of bacteriological examinations depends to a considerable extent upon what is shown by sanitary inspection and *vice versa.* Hence it would be unwise to attempt to set up any specific and inflexible standards of acceptability in terms of findings on sanitary survey or bacteriological examination or both. It is our opinion, however, that on the basis of such examinations as have been outlined, areas may be classified generally as follows with respect to their fitness for the taking of shellfish for market:
>
> (1) Areas from which the taking of shellfish should *not* be permitted.
>
> (2) Areas which may be approved for the taking of shellfish without serious question. This class includes the areas which are so protected against human fecal contamination by distance from sources of such pollution, by dilution and by the time afforded for natural purification, that there is no discoverable likelihood of dangerous contamination.
>
> (3) Areas which are intermediate between the first and second class as regards exposure to and protection against fecal pollution.

The U. S. Public Health Service after having done considerable work of this character has arrived at the conclusion that generally not more than 50 per cent of the 1 c.c. tubes in an area should show the presence of *B. coli* if that area is to be used for the taking of shellfish for the market. This is not an inflexible figure and can be used only as a guide when weighing all the evidence collected. This figure is in general use today for our field work and was applied in this specific survey.

On this basis the areas pointed out above were looked upon with suspicion, and when considered in the light of the quantities of sewage coming into the waters at the mouth of Arthur Kill and through the Narrows, the movement of the tidal current back and forth across the mouth of the Narrows, and the prevailing northwest winds, it was concluded to urge the closing of an additional area adjacent to Sandy Hook Point.

In 1925, all of the New York side of the Bay was closed, and in 1934 a quarter mile strip along the New Jersey shore line. This work added to these condemned sections a triangular piece of water beginning at Sandy Hook Point and running along the channel leading to Seguine Point near Princess Bay in New York, thence along the state boundary line which passes through Romer Shoal light.

After proper action by the New Jersey authorities this area was officially closed whereupon the New York City Board of Health opened that city's markets to products from these waters with the provision that string clams be marked "For cooking purposes only."

FUTURE OF AREA

The future of this area appears brighter. In New Jersey, Keansburg and Keyport (both immediately on the bay) have been ordered to improve their sewage treatment facilities and at Keyport a new plant is being constructed; action is progressing to clean up the Shrewsbury River further; wastes contributed to Arthur Kill by New Jersey communities will be measurably reduced by new plants for the Rahway and Elizabeth valleys both of which are under construction; certain improvements in facilities in towns discharging to the Raritan River are under state and court orders; and the operation of the new Perth Amboy plant has removed the menace of a large volume of raw sewage which was formerly discharged at a point extremely close to the shellfish beds. In New York, the new Coney Island plant will alleviate the situation at Sheepshead Bay where now 44 m.g.d. of raw sewage discharges directly east of the bay; the Wards Island plant will remove about 280 m.g. from the East River daily; and the completion of the plans for treating the sewage from Staten Island in 7 more plants will materially reduce the contributed load on the waters of the Upper Bay, Kill Van Kull, and Arthur Kill.

CONCLUSION

Extension of the safe shellfish grounds in this bay, therefore, await the installation of more sewage treatment works. A continuation of the present open area depends largely upon the efficient and unceasing operation of the plants in New Jersey located on Raritan Bay and its tributaries. Consequently, as in other cases, the life of this local industry is to a large degree dependent upon municipal authorities and sewage works operators. I trust that your efforts will all be toward making it possible for this industry to grow and flourish.

Public Health for All

JUST like disease, public health does not recognize any man-made or natural barriers dividing the people or for that matter any distinction of caste, creed, or colour, so that in this respect all are for one and one for all. The whole of the human race is liable to the *same diseases and establishes the* brotherhood and equality of man in one respect at least and as public health is a counter measure to disease its laws apply equally to all.—D. R. Mehta, M.B., The Edinburgh Congress, *J. State Med.*, XLIV, 6 (June), 1936.

Laboratory Problems in the Control of Meningococcus Meningitis*

ROSS L. LAYBOURN, F.A.P.H.A.

Bacteriologist in Charge, Public Health Laboratory, Kansas State Board of Health, Topeka, Kan.

OUTBREAKS of meningococcus meningitis offer adequate evidence of the futility of the control measures which have been employed, and the literature gives slight promise of the immediate development of effective control measures which can be generally applied. Carriers have commonly been considered more important in the transmission of the disease than cases, yet carrier surveys, as usually carried out, have complicated the administrative problems involved without aiding materially in control. The carrier incidence in a group may run above 35 per cent and the outbreak abate without their segregation. In other instances, the segregation of carriers, as found, has had no influence on the course of the outbreak. As a result of such observations the wholesale meningococcus carrier survey has fallen into disrepute, probably to the best interests of all concerned.

The wholesale carrier survey has, at least, served to emphasize the fact that there are many problems in the bacteriology, infection, immunity, and epidemiology of meningococcus meningitis which have not been worked out or have been ignored in routine work. The responsibility for improvement in methods of control rests squarely on the laboratory, and if any success is to be attained the laboratory worker must approach each outbreak as an applied research problem rather than with the aim of getting the largest number of carrier cultures made in the least possible time. This premise justifies this incomplete presentation of certain theoretical phases of the subject and the fragmentary observations cited as offering possibly some basis or stimulus for studies on the epidemiology of the disease.

No small part of the confusion which exists arises from attempts to evaluate observations and findings on the same basis as is used in considering the more highly communicable diseases. A meningococcus meningitis outbreak cannot be compared with a typhoid outbreak and a meningococcus carrier does not have the same epidemiological significance as a typhoid carrier. A better understanding of the problem may be obtained by a classification of communicable diseases which divides them into those of universal susceptibility and definite epidemiology and those of limited susceptibility and obscure epidemiology.

I. DISEASES OF UNIVERSAL SUSCEPTIBILITY AND DEFINITE EPIDEMIOLOGY

Typhoid fever, smallpox, mumps, and measles offer examples of diseases

* To be read before the Laboratory Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

of universal susceptibility and definite epidemiology, to which, as a group, the following characteristics may be ascribed:

A. Causative organisms are aggressive invaders of the body, regardless of the severity of the symptoms produced when an invasion has been accomplished.

B. Populations are universally susceptible, unless naturally or artificially immunized.

C. Susceptibility is not related to a lowered general resistance.

D. The carrier level is relatively low in those in which carriers are known to exist.

E. Carriers are almost universally a menace.

F. Cases are usually referable to a known preceding case or carrier.

G. Clinically mild and atypical cases are much less common than in the second group.

H. Control measures are fairly well established.

II. DISEASES OF LIMITED SUSCEPTIBILITY AND OBSCURE EPIDEMIOLOGY

Meningococcus meningitis, poliomyelitis, the pneumonias, and undulant fever are examples of this group, and as a result of extensive immunization diphtheria also may possibly be included in this group. The chief characteristics of the group are:

A. Causative organisms are not aggressive invaders of the body. Virulence involves at least 2 factors: the aggressiveness of the organism as an invader, and the ability to produce severe symptoms when an invasion has been accomplished. These 2 factors are well correlated in diseases of universal susceptibility, but the correlation is not so marked among the diseases of limited susceptibility. The meningococcus is ordinarily a poor invader at best, but even the poorest invaders among the meningococci may attack with much fury when, through some combination of circumstances, an invasion has been accomplished.

B. Only a limited portion of the population is susceptible. If the intradermal skin test with meningococcus toxin, adjusted by tests on newly developed cases of meningococcus meningitis, is a reliable index, findings bear out this statement. The writer has made 626 such tests on institutional and residential populations among which cases of meningococcus meningitis had occurred. On the basis of the edema and erythema produced, 25.7 per cent were slightly susceptible and 1.5 per cent were highly susceptible. Younger groups showed a greater susceptibility than older.

C. A lowered general resistance is usually essential to an invasion by organisms of average virulence, even in the susceptible group. Case histories in meningococcus meningitis usually reveal some predisposing factor which has tended to lower the resistance of the individual. These include upper respiratory infections, otitis media, gastrointestinal upsets, extreme and prolonged fatigue, prolonged exposure to inclement weather, the excessive use of alcohol, and numerous less easily detected causes.

D. The carrier level is relatively high in diseases in which carriers are known to exist. Several instances have been reported in which the meningococcus carrier incidence exceeded 50 per cent. Glover [1] considers that when the carrier level reaches 20 per cent, the community is in danger of an outbreak of meningitis.

E. Carriers are not universally a menace. Effective meningococcus carriers are probably few in number. One error in the carrier survey has been a lack of understanding of the fact that there are epidemic, non-epidemic or sporadic, and probably saprophytic strains of the meningococcus, similar in characteristics to those reported among the pneumococci. This grouping fits in nicely with the generally accepted type classification of meningococci. The actual epidemiological basis for the classification is that phase of virulence which has to do with the aggressiveness of the organism as an invader of the

deeper tissues. Rake[2] groups meningococci on the basis of Gordon's classification:

Type I–III: Parasitic or epidemic and responsible for nearly all the large epidemics and most of the small ones.

Type II: Normally a saprophyte, frequently present in the throats of normal individuals. Can also act as a parasite and produce sporadic cases of the disease and even limited epidemics.

Other types: Saprophytes, present in the throats of normal individuals where they seem to cause no harm. Only occasionally do they cause a sporadic case of meningitis.

In general, the carriers of non-epidemic and saprophytic strains of the meningococcus are more consistently positive on repeated culture and the condition is of longer duration than is the case with carriers of epidemic strains. The non-epidemic and saprophytic strains are more easily grown than are the epidemic strains. It seems likely, then, that most of the carriers detected in routine carrier surveys have been of no epidemiological significance.

The dangerous carrier of epidemic strains is frequently of the chronic, intermittent type, capable of transmitting massive infections at times but with intervals when the meningococcus is apparently not present in the superficial tissues of the posterior nasopharynx. An individual may be able to resist the attack of a few poor invaders but succumb to a large number of these same organisms when his general resistance has been lowered by some predisposing factor. Limited studies on chronic, intermittent carriers of epidemic strains have shown that individuals may yield practically pure cultures of meningococci at times, while at other times few or none are found.

This intermittent character of effective carriers is one factor which contributes to the baffling epidemiological picture often observed and accounts, in some instances at least, for the failure of the carrier survey. The writer[3] has reported a carrier of Gordon Type I–III meningococci who appeared to have been responsible for 5 cases in an institution, distributed over a period of about 9 months and who continued to give an occasional positive culture for 5 months more. Rake[4] has reported carriers of this sort in which repeated cultures were negative for periods of several months, after which positive cultures were again obtained. The unreliability of the usual regulations for the release of carriers becomes apparent in the light of such findings.

Since the inference has been made that the technic commonly used in carrier surveys may not always detect the dangerous carriers, a word regarding technic may not be amiss. The technic which gives some assurance of isolating and identifying the less easily cultivated epidemic strains of the meningococcus, lends itself better to an intensive and prolonged study of a carefully selected group than to a single culturing of an extensive group selected by administrative order or in a haphazard manner. The writer has set an arbitrary, maximum limit of 40 cultures per day when working alone in the field, and this may be too high for best results. Space does not permit a detailed description of the technic involved, and the reader is referred to the excellent outline of the subject by Branham[5] for further information. Certain points will bear emphasis, however: (1) There are no reliable short-cuts in technic, such as the use of Olitsky's medium; (2) the identification of freshly isolated strains of the meningococcus cannot always be safely based on agglutination reactions, to the exclusion of carbohydrate fermentation; (3) typings must be made, without exception, if the findings are to be of any epidemiological significance.

F. Cases are not usually referable to a preceding case or carrier, as found. This statement holds true in the ma-

jority of meningococcus meningitis outbreaks. Painstaking and detailed epidemiological investigations have led on several occasions to the selection of a small group which, upon repeated culturing, has yielded a chronic intermittent carrier who fitted into the epidemiological picture and whose removal coincided with the end of the outbreak.

G. Clinically mild and atypical cases are very common and may exceed the clinically typical cases in number. Ordinarily only meningococcus infections involving the meninges are recognized; yet there is considerable evidence that a meningococcus septicemia always precedes the meningitis, and meningococcus septicemias without meningeal involvement have been repeatedly reported. Meningococcus meningitis following sinus involvement occurs frequently enough to suggest that the meningococcus may be the causative organism in many sinus infections, rather than a secondary invader. Upper respiratory infections are also numerous during an outbreak of meningococcus meningitis. Are these the usual run of respiratory infections or are these individuals suffering from a mild form of local meningococcus infection as has been suggested by Mink [6] and others.

Certainly meningococcus infections without meningeal involvement offer greater opportunities for the dissemination of the parasitic types of organism than cases of meningitis, and considerable study may well be devoted to the problem.

H. Control measures are not as well established as in the group of diseases of universal susceptibility. The measures used with the first group of diseases are employed as a matter of form, but the special measures which have proved slightly more effective are those which contribute to the maintenance of a high level of general resistance in the individual.

These characteristics of diseases of limited susceptibility and obscure epidemiology cast some light on the problems involved. Outbreaks will be cited as illustrative of some of these points and extensive observations along these lines may give some information of value in the control of the disease.

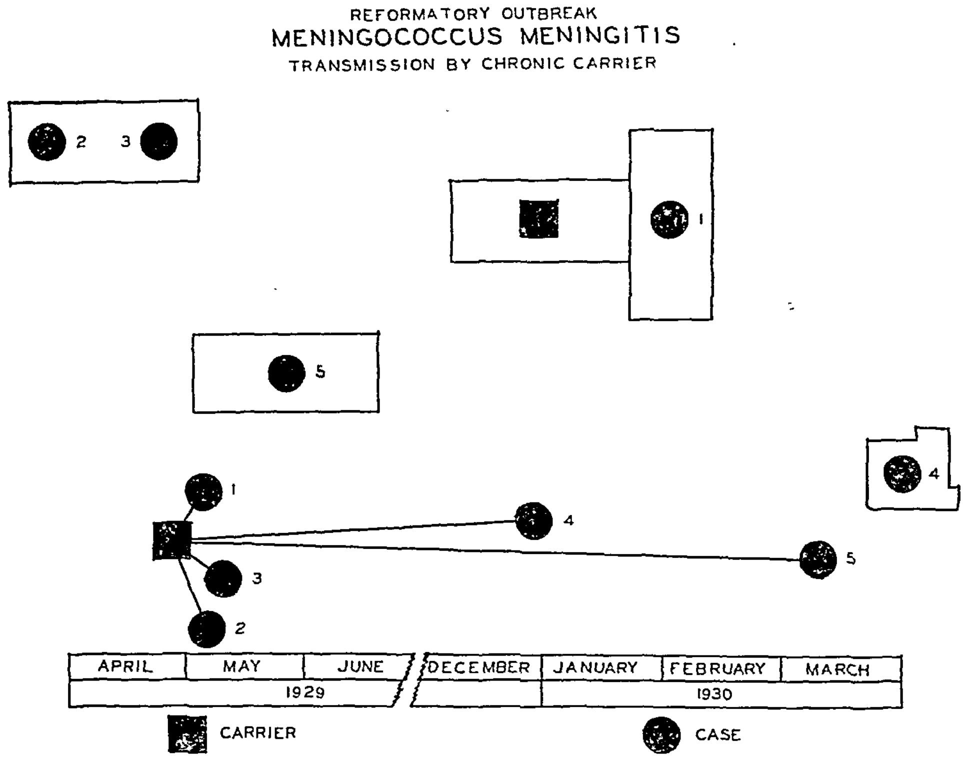
Some mention should be made of the use of meningococcus toxin. The production of meningococcus toxin by Ferry, Norton, and Steele [7] has introduced the possibility of its use for intradermal skin tests, as an index of immunity, and for artificial immunization. Kuhns [8] and the writer have both done some work along these lines but extensive use and prolonged observation will be necessary before definite conclusions may be drawn.

The almost universal observation of a lowered general resistance as a predisposing factor for the development of cases of meningococcus meningitis, involving organisms of average virulence, suggests that the intradermal skin test may only give an index of one of several factors concerned in susceptibility to the disease.

Limited experience with the use of raw meningococcus toxin as an immunizing agent also indicates that the amount which can be injected without causing severe reactions is not sufficient to produce as high a degree of immunity against the intradermal skin test as is desirable. There are also some observations that suggest that the use of meningococcus toxin may only immunize against certain minor clinical symptoms, similar to what has been alleged in connection with the immunization against scarlet fever with streptococcus toxin.

These statements are not intended as a criticism but as a caution against over-enthusiasm and inadequately supported claims. The only communicable diseases which may really be considered as controllable are those for which an easily used, active immunization has

FIGURE I



been developed. For meningococcus meningitis, whether this be meningococcus toxin, an autolyzed meningococcus filtrate or some other product, studies aimed at the production of an effective agent for active immunization seem to offer the greatest promise of successful control of the disease.

The following outbreaks of meningococcus meningitis serve to emphasize certain of the characteristics of the disease which have been outlined above.

1. REFORMATORY OUTBREAK

This outbreak occurred in a state reformatory with about 650 inmates and 50 officers and their families.

Figure I shows both the geographical and chronological distribution of cases. Five cases occurred, 3 among officers (Cases 1, 4, and 5) from 35 to 67 years of age, and 2 among inmates (Cases 2 and 3) under 21 years of age. Wholesale carrier surveys, made after the development of both the 3rd and 4th cases, were of no value in control.

The organism involved in the last 2 cases was identified as a Gordon Type I–III meningococcus and it was assumed that there was probably a chronic carrier of this organism either among the officers or their families, since 3 of the 5 cases had been officers. The next culturing was limited to officers, their families, and "H" Company, the last case having been the captain in charge of "H" Company.

No carriers of Type I–III meningococci were found among the officers or their families, but one member of "H" Company, who had given negative cultures on both the wholesale carrier surveys, gave practically a pure culture of meningococcus which could not be distinguished from those isolated from the spinal fluid of the last 2 cases. The relation of this carrier to the cases was as follows:

April 25, 1929—Carrier committed to the reformatory, assigned to "H" Company and detailed to the rock quarry force.

May 4, 1929—Case 1 (the captain in charge of the rock quarry force) developed meningococcus meningitis. He was a robust individual, apparently in the best of health, who had returned from a week's spree on April 27, 2 days after the carrier entered the reformatory. In the 2 or 3 days after his return to duty, he had helped the carrier lift heavy rocks. The explosive exhalation of breath while under the strain of this work had given ample opportunity for droplet infection.

May 8, 1929—Case 2 ("G" Company) developed meningococcus meningitis. He was also assigned to the rock quarry force and had been a friend of the carrier before entering the reformatory. He was an undernourished individual who had contracted a severe cold about 3 days prior to the appearance of meningeal symptoms. Ample opportunity for infection was given both at work and through the practice of passing a pipe from mouth to mouth while on the recreation grounds. Case 3 also participated with these 2 in this practice.

May 13, 1929—Case 3 ("G" Company) developed meningococcus meningitis. Occupied the bunk next to Case 2 in quarters and was a close associate of both the carrier and Case 2. He was undernourished, anemic, and was noted for repeated admittances to the infirmary on diagnosis of hysteria.

December 26, 1929—Case 4 (Superintendent of the reformatory) developed meningococcus meningitis. He was an obese, elderly individual who had lost 20 lb. in the month prior to the development of meningitis as a result of a severe, protracted cold and the worries incident to assuming management of the reformatory.

The carrier had escaped from the institution and upon his return was required to report in person to the superintendent daily. The superintendent made it a practice to get extremely close to those with whom he conversed, thus increasing the opportunities for droplet infection. He developed the disease 7 days after his first interview with the carrier.

March 7, 1930—Case 5 (the captain in charge of "H" Company) developed meningococcus meningitis. He had had a severe gastrointestinal upset a few days before. He probably acquired his infection when he forced the carrier against the wall and choked him, in quelling a disturbance in quarters 6 days prior to the onset of his illness.

This carrier was cultured at frequent intervals over 5 months. The majority of cultures failed to show meningococcus. An occasional culture showed a few meningococcus colonies and twice almost pure cultures were obtained, establishing his status as a chronic, intermittent carrier capable at times of transmitting massive infections.

The writer[3] has reported a similar outbreak in a state penitentiary, involving a Gordon Type I meningococcus. Wholesale carrier surveys were of no value in control and the geographical and chronological distribution of cases was similar to the reformatory outbreak. Epidemiological studies revealed that all the cases had occurred among skilled men in the building trades who worked together on construction jobs about the prison. Careful culturing of the remainder of this limited group revealed a chronic, intermittent carrier who was quartered in a cell house where no cases of the disease had developed. As with the reformatory outbreak, the institution was free from meningococcus meningitis for a number of years following the removal of the chronic carrier.

These outbreaks emphasize the following points:

A. Carriers of sporadic and saprophytic types of the meningococcus are of no epidemiological significance in outbreaks.

B. The dangerous carrier is of the chronic, intermittent type who is harboring an epidemic strain of the organism and who is capable of transmitting massive infections at times.

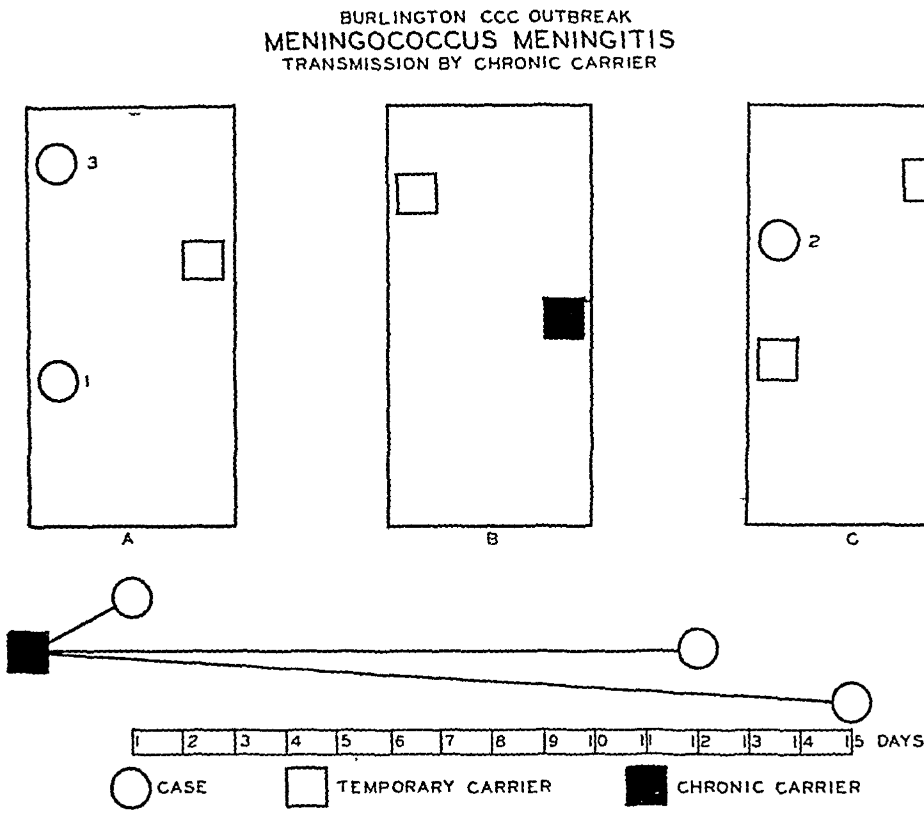
C. A lowered general resistance of the individual, coupled with a massive infection is essential for a successful invasion by meningococci of average aggressiveness.

D. Careful epidemiological studies may be of value in selecting the group which includes the effective carrier.

2. BURLINGTON CCC OUTBREAK

This outbreak occurred in a Civilian Conservation Corps Camp at Burling-

FIGURE II



ton, Kan., in November and December, 1935. The personnel of the camp included over 200 enrollees, officers and supervisors who were quartered in cantonment type barracks.

Figure II shows the chronological distribution of cases and their location in barracks. Three cases occurred at intervals of 12 and 3 days, respectively, among enrollees. Two cases (Cases 1 and 3) were quartered in Barrack A, and 1 case (Case 2) in Barrack C. Typings were not entirely satisfactory because of broad agglutinations and absorptions, but somewhat better results were obtained with Type III sera than with other types and the organism was considered an epidemic type.

Preliminary epidemiological investigations gave no significant leads and it was decided to culture the entire camp personnel in groups of a size in which it would not be necessary to sacrifice accuracy of technic to speed. Thirty-one, or 14.2 per cent, of the 217 persons cultured were found to be meningococcus carriers.

This was the first outbreak handled by the writer in which he had the courage of his convictions as regards the carriers of epidemic and non-epidemic strains of the meningococcus. Of the 31 carriers identified, 26 yielded non-epidemic or saprophytic strains and 5 epidemic strains. Only the 5 carriers of epidemic strains were isolated. One of these 5 carriers, quartered in Barrack B where no cases of the disease had developed, proved to be a chronic, intermittent carrier of an organism which closely resembled those recovered

from 2 cases. He had been closely associated with the 2 patients either in tussles or contests of strength and skill prior to their illness, which may account for their infection.

The writer had charge of this outbreak which Kuhns[8] has cited as an example of successful control through the use of meningococcus toxin for immunization, in which opinion the writer does not concur. Skin tests for susceptibility were read jointly by the camp surgeon and the writer on December 5, the day that the carriers of epidemic strains of meningococci were isolated. No new cases developed between December 5 and December 20, when the 4th dose of meningococcus toxin was given to the 89 skin test reactors among the camp personnel. Certainly the toxin cannot be given credit for the prevention during a considerable portion of the immunization period. This absence of cases may be due to the vagaries of the epidemiology of the disease, but the whole outbreak so closely resembles those of the reformatory and penitentiary mentioned above, as well as others in the writer's experience, where removal of chronic intermittent carriers of epidemic types of meningococci has coincided with the end of the outbreak, that this fact cannot be ignored.

3. SPEARVILLE CARRIER

The history of this carrier presents some interesting possibilities both as to the duration of the chronic carrier state and the production of cases by carriers of non-epidemic or sporadic strains of the organism.

The mother of a family of 11 children, residing on a large wheat farm, had meningococcus meningitis in 1928 and recovered. Since that time, 3 of her 11 children have developed the disease: 1 case, fatal, in February, 1930, 1 which recovered, March, 1930, and 1 which recovered in March, 1936.

Cultures made early in June, 1936, revealed the fact that both the mother and her 3 year old daughter were carrying a Gordon Type II (sporadic) meningococcus which had rather broad cross-agglutination and absorption reactions with both Types I and III sera.

The number and distribution of cases suggests that this woman has been a chronic, intermittent carrier of a non-epidemic strain of meningococcus since her recovery in 1928. A culture made in August, 1936, was negative, and additional studies will be made.

Skin tests made with polyvalent meningococcus toxin in June, 1936, gave negative reactions on the mother and the 2 children who have had the disease. Of the remainder of the family, 5 gave 1 + skin tests, 1 a 2 + test and 1 a 4 + test. The 4 + test is comparable to the skin test susceptibility of newly developed cases of the meningococcus meningitis which have been tested. These results suggest that other factors than skin test susceptibility are more important than the skin test in the transmission of the disease.

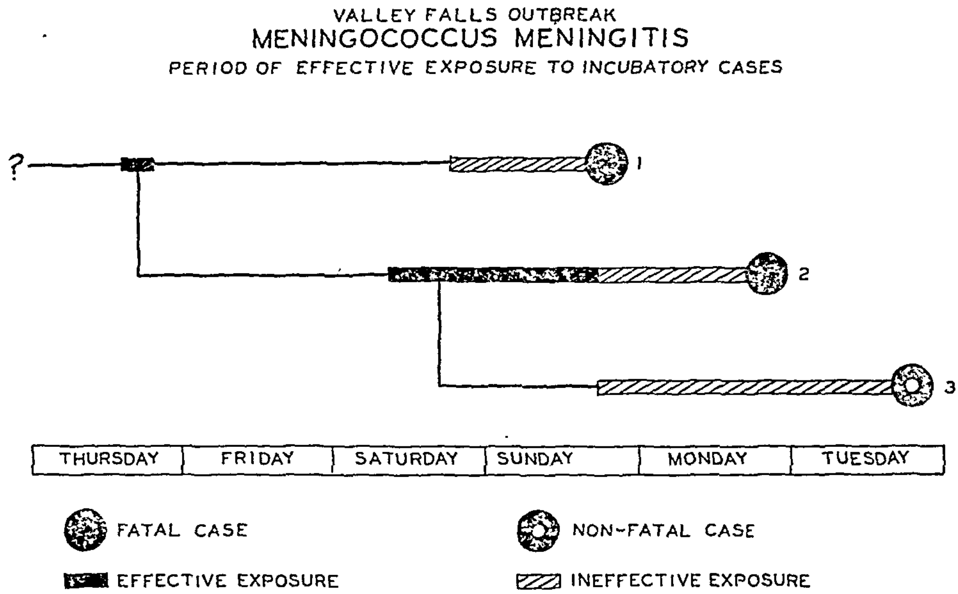
Transmission of meningococcus meningitis by clinical cases of the disease has not appeared to be as common as transmission by carriers. The following outbreaks illustrate the usual and exceptionally rare types of transmission by cases:

4. VALLEY FALLS OUTBREAK

Three cases developed on successive days, 2 were high school students and the 3rd a sister of the 2nd patient, was a grade school pupil (Figure III).

The source of infection in the first case is not known, but in view of the rather definite incubation period in Cases 2 and 3, the patient probably acquired his infection either Wednesday night or Thursday morning. Case 2 acquired his infection from Case 1 while returning from a basket ball game

FIGURE III



in an open truck. The 2 boys became chilly during the 20 mile trip and put their heads together under a blanket, giving ample opportunity for transference of the organism from Case 1, then in the early incubation stage. Patient 3 was the sister of patient 2 and was at home with her brother during the early stages of his incubation period. A culture of Case 2 taken a few hours before the development of clinical symptoms failed to show the presence of meningococci.

Each of these patients was in contact with several children in their respective families during that stage of the incubation period just prior to the development of clinical symptoms and no cases resulted, while exposures during the early stages of the incubation period were productive of cases. All of the children exposed were suffering from severe colds with laryngeal involvement, which would be considered a predisposing factor to infection, yet cultures taken shortly after the development of cases showed no meningococci.

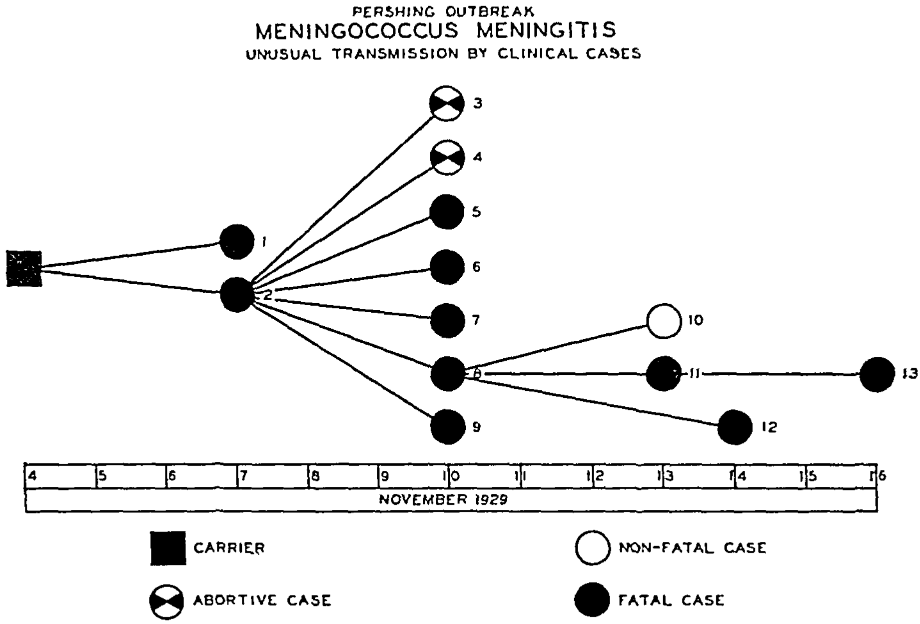
This illustrates the common observation that clinical cases are most infectious during the first 24 or 36 hours of the incubation period when large numbers of meningococci are present in the posterior nasopharynx and massive infections can be transmitted. In most instances the organisms enter the deeper tissues and disappear from the nasopharynx before the appearance of clinical symptoms, and the case is no longer infectious.

5. PERSHING OUTBREAK

This has been reported [3] but is briefly presented because it graphically shows the rather unusual transmission of the disease by fulminating cases after clinical symptoms have developed. This outbreak was due to a Gordon Type I organism of exceptional aggressiveness as an invader.

Figure IV shows the chronological grouping of cases and sources of infection. Most of the cases were persons of middle age, the incubation period was 3 days, and most of the patients died in from 11 to 14 hours after the appearance of the initial symptoms. A total

FIGURE IV



of 23 persons were exposed to these cases during the clinical stages, 11 of whom developed the disease.

While such effective transmission will not ordinarily be encountered, the possibility must be considered in fulminating outbreaks of the disease. While such outbreaks are spectacular and terrifying, they offer a much simpler problem of control than the usual type.

SUMMARY

The theories presented and outbreaks cited cast some light on the problems involved in the transmission of meningococcus meningitis and somewhat similar studies may be of material assistance in the development of methods of control of the disease.

Studies dealing with the following problems are suggested:

A. Epidemiological significance of what have been termed epidemic, non-epidemic, and saprophytic strains of the meningococcus.

B. The prevalence and epidemiological significance of meningococcus infections other than meningitis.

C. The epidemiological relationships of chronic, intermittent carriers to sporadic cases and outbreaks of meningococcus meningitis.

D. Improvement in the technic of culturing meningococcus carriers.

E. Predisposing factors to meningococcus infection.

F. The development of reliable and easily applied tests for immunity to meningococcus meningitis as well as effective methods of immunization.

Interstate Sanitation Compact and Its Implications*

C. A. HOLMQUIST, F.A.P.H.A.

Director, Division of Sanitation, New York State Department of Health, Albany, N. Y.

ALTHOUGH the New York State Department of Health had long realized that it was imperative to protect our streams from pollution in order to conserve the public water supplies derived from surface sources, no definite action was taken by the state to control stream pollution until the so-called "anti-pollution" law was enacted in 1903. By that time nearly all of our large rivers and many of our small streams had become seriously polluted, only 3 relatively small municipalities having installed sewage treatment plants. The New York law is similar to the anti-pollution laws of a number of other states, and in general prohibits the discharge of sewage and industrial wastes into any of the waters of the state without the approval of the State Commissioner of Health. However, municipalities and industrial plants which were discharging sewage and wastes prior to that time were exempted from the operation of the law.

The State Department of Health has had many obstacles to overcome in its efforts to clean up our streams. Municipalities and industrial concerns had come to look upon the discharge of untreated sewage and wastes into streams as a vested right and seemed to resent any interference with this practice. The constitutional limitations on the bonding power of municipalities and the high cost of the interception and treatment of sewage has delayed our campaign against stream pollution. Experience in New York indicates that the cost of providing for the interception and treatment of sewage of municipalities varies from $5 to as high as $100 per capita with an average of $25. The cost of such work for the City of New York alone is estimated at between $243,000,000 and $378,000,000, depending upon the degree of treatment provided.

Although municipal officials usually realize the necessity for providing sewage treatment, taxpayers are very often loath to vote favorably on propositions to bond municipalities for such projects. They feel that sewage treatment is primarily for the benefit of downstream communities and that neither they nor the community itself will receive any direct benefit therefrom.

Although the department has required the installation of sewage treatment works in connection with all new

* To be read at a Joint Session of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

sewer systems constructed since the anti-pollution law was enacted in 1903, and as a result there are now 209 sewage treatment plants serving a population of nearly 2,500,000, the sewage from a population considerably greater than the entire population of the state in 1903 is being discharged without any treatment into the waters of the state. This is due in a large measure to the phenomenal growth of New York City, which has a population greater than that of the entire state in 1900, but treats only a small portion of its sewage.

The most important and far reaching coöperative effort so far undertaken to control pollution is the Interstate Sanitation Compact that has been drawn up by the states of New York, New Jersey, and Connecticut. The rapidly increasing pollution of the tidal waters in the New York metropolitan area has been a matter of grave concern to the state and local health departments of these states. Although the problem of abating this pollution has been studied for a great many years by various commissions, only a relatively small percentage of the sewage in the New York metropolitan area is receiving any treatment at present. The sewage treatment plants installed so far have been constructed primarily to give local relief where the conditions were particularly objectionable. The volume of sewage so treated has had no appreciable effect on the general problem and has not kept pace with the tremendous growth of this area.

Aside from the high cost of interception and treatment of the sewage for this thickly populated metropolitan area the State Departments of Health of the 3 states involved appear to have been somewhat reluctant to require the municipalities under their jurisdiction to install sewage treatment works, realizing that unless all of the states did likewise their efforts would be nullified to a large extent. Furthermore, before the Interstate Sanitation Compact was consummated there were no uniform or accepted standards to act as a guide as to the degree of treatment to provide.

Some conception of the magnitude of the problem may be gained from the fact that nearly 10 per cent of the entire population of the United States is concentrated in the New York metropolitan area and that the sewage from over 12,000,000 persons, amounting to over 1,300,000,000 gallons, and the trade wastes from some 100,000 industries are discharged daily into the coastal and harbor waters of this district. This quantity of sewage has for years exceeded the assimilating power of these waters and has resulted in the entire depletion of the dissolved oxygen content of the water in a number of areas during the summer months. Of the total population contributing sewage, about 74 per cent are in New York State, 20 per cent in New Jersey, and about 6 per cent in Connecticut.

It has been the general belief that the sewage and wastes discharged into the waters in New York Harbor and its tributaries are promptly carried out to sea by the large quantities of pure water of the Hudson River, Long Island Sound, and the Atlantic Ocean. The fact is that the sewage in the harbor drifts back and forth for days by the action of the tides and that less than 10 per cent of the tidal flow at the Narrows consists of new sea water.

This enormous quantity of sewage and industrial wastes discharged daily carries hundreds of thousands of tons of sewage solids into the surrounding waters each year, about half of which is putrescible organic matter. This material is deposited in the form of putrescible sludge in the steamship slips and channels of the harbor. Extensive dredging operations have to be carried on each year in order to

free the slips and channels of this sludge and other deposits.

Unless this pollution is checked it will be only a matter of time before it will render impossible the enjoyment of the great public beaches built at a cost of millions of dollars and giving recreation and healthful enjoyment to millions of people. Already a number of beaches have been closed to bathing by the New York City Department of Health.

The effect of this pollution upon fish life has been marked. There is practically no fish life existing in certain areas of the district, due largely to the reduction of the dissolved oxygen content of the water. The economic loss due to this condition is hard to estimate. Some of the most productive shellfish areas in the New York metropolitan area have been condemned for shellfish cultivation. According to data furnished by the Conservation Department of New York State there has been a reduction in the number of acres of tidal waters under lease of franchise in this area for the propagation of oysters from 24,400 acres in 1915 to 6,700 acres in 1935. Furthermore, the cultivation of shellfish is prohibited in 81,000 acres of land under water in this district. This condition has resulted not only in a tremendous loss to the shellfish industry but also a loss of revenue to the State of New York.

The pollution of bathing beaches and shellfish beds finally aroused the public and certain metropolitan newspapers to a realization of the seriousness of the pollution problem, and resulted in the calling of a number of conferences in New York City during 1930 to consider ways and means of correcting these conditions. These conferences were presided over by Senator Royal S Copeland, formerly Commissioner of Health of New York City, and were attended by representatives of federal, state, and municipal authorities, as well as other interested citizens.

As a result the 3 states of New York, New Jersey, and Connecticut early in 1931 passed laws creating a temporary Tri-State Treaty Commission directed to

> . . . formulate the terms of a treaty between the 3 states and the federal government in the matter of the prevention and eradication of contamination and pollution of the natural waters flowing or situated between the states of New York and New Jersey or the states of New York and Connecticut and the natural waterways of said states flowing to any such natural waterways and the legislation, state and federal, necessary to make such recommendations effective.

The Tri-State Commission appointed by the governors of the 3 states was non-partisan and was composed of men whose actions were governed solely by consideration of the best public interest. They were assisted by the best engineering and expert talent of the states involved, and the Compact as finally evolved stands out as one of the great achievements in interstate coöperation.

The first meeting of the Tri-State Treaty Commission was held in New York City on June 3, 1931. A number of sub-committees, including the Committee of Engineering and Research, of which the writer was a member, were organized. It was the duty of this committee to fix the areas to be included within the proposed Interstate Sanitation District and to draw up standards of purity of sewage effluent and of the waters within the treaty area.

The legislation legalizing the Compact and standards in so far as New York State is concerned was passed unanimously during the closing days of the 1932 legislature and signed by Governor Roosevelt on March 30, 1932. Although bills legalizing the Compact were introduced in the New Jersey legislature each year since that time, it was not until July, 1935, that the necessary legislation was passed and

signed by Governor Hoffman. The laws passed by New Jersey, however, differed in a number of essential features from those passed by New York in 1932, so that it was necessary for New York to enact identical laws in order to put the Compact into effect in so far as New York and New Jersey are concerned. Such legislation was introduced on January 2 of this year, passed by the legislature on January 14, and signed by Governor Lehman on January 17, 1936. The Compact was approved by a joint resolution of Congress on August 27, 1935. The Compact so far as Connecticut is concerned will become effective whenever that state passes laws identical with those of the other 2 states. The Interstate Sanitation Commission, comprising members from these 2 states, has organized and is now functioning.

Stated in simple terms, the Compact contemplates the elimination of offensive pollution, the making of all beaches in the region safe for bathing and recreational purposes, and the return to shellfish culture of many of the areas now condemned. In the words of the Compact:

> Each of the signatory states pledges each to the other faithful coöperation in the control of future pollution and agrees to provide for the abatement of existing pollution in the tidal and coastal waters in the adjacent portions of the signatory states defined herein as coming within the district, and consistent with such object, to enact adequate legislation which will enable each of the signatory states to put and maintain the waters thereof in a satisfactory sanitary condition, and particularly to protect public health; to render safe such waters as are now used or may later become available for bathing and recreational purposes; to abate and eliminate such pollution as becomes obnoxious or causes a nuisance; to permit the maintenance of major fish life, shellfish and marine life in waters now available or that may by practicable means be made available for the development of such fish, shellfish or marine life; to prevent oil, grease or solids from being carried on the surface of the water; to prevent the formation of sludge deposits along the shores or in the waterways; and with the fulfillment of these objectives to abate and avoid incurring unnecessary economic loss by safeguarding the rights of the public in its varied legitimate uses of the waters of the district.

The area included within the Interstate Sanitation District covered by the Compact comprises the tidal waters in the Metropolitan District, including Newark Bay, Upper and Lower New York Bays, Sandy Hook Bay, and Raritan Bay, the Hudson River north to the northerly boundary line of Rockland and Westchester Counties; Long Island Sound as far east as the easterly side of New Haven Harbor at Morgan Point in Connecticut and the easterly side of Port Jefferson Harbor on Long Island; and the Atlantic Ocean to the easterly side of Fire Island Inlet on Long Island.

With respect to the standards of purity, the Compact provides

> . . . that where tidal waters are used for such varied purposes as bathing, navigation, shellfish culture, the development of fish life, and the disposal of wastes, no single standard of purity is practicable in all parts of the district.

The waters, therefore, were divided into 2 general classes—

> Class A waters in which the designated water areas are expected to be used primarily for recreational purposes, shellfish culture, and the development of fish life.
>
> Class B waters in which the designated water areas are not expected to be used primarily for recreational purposes, shellfish culture, or the development of fish life.

After a careful study and consideration of the local factors involved, the following minimum standards were adopted by the Tri-State Commission:

> 1. All sewage discharged or permitted to flow into Class "A" waters of the district shall first have been so treated as:
>
> a. To remove all floating solids and at least 60 per cent of the suspended solids.
>
> b. To effect a reduction of organisms of the *B. coli* group (intestinal bacilli) so that the probable number of such organisms shall not exceed 1 per c.c. in more than 50 per cent of

the samples of sewage effluent, provided, however, that in the case of discharge into waters used primarily for bathing this bacterial standard need not be required except during the bathing season.

c. To effect a reduction in the oxygen demand of the sewage effluent sufficient to maintain an average dissolved oxygen content in the tidal waters of the district and in the general vicinity of the point of discharge of the sewage in those waters, at a depth of about 5 feet below the surface, of not less than 50 per cent saturation during any week of the year.

2. All sewage discharged or permitted to flow into Class "B" waters of the district shall first have been so treated as:

a. To remove all floating solids and at least 10 per cent of the suspended solids, or such additional percentage as may by reason of local conditions be necessary to avoid the formation of sludge deposits in Class "B" waters of the district.

b. To effect a reduction in the oxygen demand of the sewage effluent sufficient to maintain an average dissolved oxygen content in the tidal waters of the district and in the general vicinity of the point of discharge of the sewage into those waters, at a depth of about 5 feet below the surface, or not less than 30 per cent saturation during any week of the year.

The Compact also provides that all sewage discharged or permitted to flow into any stream tributary to the tidal waters of the district shall be so treated if necessary as to maintain such stream in a sanitary condition at least equal to the requirements laid down for the tidal waters into which it flows.

The Compact sets up a permanent Inter-State Sanitation Commission with authority to make investigations, conduct hearings, and prescribe by orders a reasonable date on or before which each municipality shall treat its sewage in accordance with the standards specified in the Compact. It also provides that nothing in it shall be construed to repeal or prevent the enactment of any legislation or the enforcement of any requirements of any signatory state imposing additional conditions or restrictions to lessen or prevent the pollution of water within its jurisdiction and requires that the Interstate Commission shall coöperate with the respective state authorities having jurisdiction over stream pollution with a view to coordinating their activities and securing the most satisfactory results. For this purpose the Interstate Commission is authorized to prepare a general plan of the most practical and economical method of securing conformity with the Compact and submit such plan to the governor and the legislature of each state and to the state agencies having charge of sewage problems in the respective states.

It should be noted that the standards stipulate the results to be obtained, leaving it to the states and municipalities involved as to how the results shall be reached. The minimum standards adopted, however, can in most cases be met by simple and well known methods of sewage treatment. The tests required to determine if the standards with respect to the sewage effluent or the receiving waters are complied with are also simple and lend themselves to easy determination.

It is felt that the standards for Class A waters are sufficiently high to protect public health and fish life. In fact the *B. coli* standard for sewage effluent is only slightly less stringent than the minimum standards for swimming pools prescribed by the New York State Sanitary Code and are more stringent than the minimum requirements for bathing beaches of New York City.

If the standards set up for Class B waters are met, visible solids of recognizable sewage origin will be removed and no public nuisance or menace to health will be created in such waters. In fact, odor nuisances are not created so long as the dissolved oxygen is not depleted. If it had not been considered desirable to protect fish life a lower dissolved oxygen content would have been permissible.

The fact that shad are still able to

penetrate the pollution barrier of the waters in the metropolitan area and reach the spawning grounds in the Hudson River at the Kingston flats 80 miles above New York Harbor every year under the present low oxygen content of these waters seems to be conclusive evidence that 30 per cent saturation should not be inimicable to shad. Furthermore, if the dissolved oxygen in the vicinity of the outlet from disposal plants does not fall below 30 per cent, the dissolved oxygen in the main body of the water will be considerably greater.

It is believed that if the Compact is faithfully carried out by the states involved, it will expedite the cleaning up of the tidal waters in the metropolitan area; will protect public health and the bathing beaches used by millions of bathers each year; and will return to shellfish culture many of the areas now condemned.

Although the health departments of a number of states have entered into agreements to control the pollution of interstate streams, this is the first time that legal representatives of 3 sovereign states have actually drawn up a compact pledging the abatement of the pollution of interstate waters. The ratification of this Compact should have far reaching effect on the control of stream pollution not only in the states involved but also in other states, which may have similar problems, and should give impetus to the battle for the conservation of our streams and waterways, which constitute one of our most valuable natural resources.

This Compact has already created considerable interest, and the results produced by its enforcement will be watched keenly by state officials charged with the duty of controlling stream pollution. It is probable that other states having similar problems will follow the example set by New York, New Jersey, and Connecticut. The consummation of interstate pollution compacts, however, is apt to be a slow process. It required nearly 5 years to have the Compact under consideration ratified. It would probably have taken considerably longer had it not been for the seriousness of the pollution which threatened the closing of bathing beaches used for the healthful recreation of millions of people each year in the metropolitan area and the destruction of millions of dollars worth of shore property.

There is a growing feeling among state health officials that the problem of controlling stream pollution is too big for the states to handle alone and there is an increasing demand for federal coöperation in the control of stream pollution and for federal aid in financing sewage disposal projects, especially where interstate streams and international boundary waters are involved. This is substantially the conclusion reached by the Special Advisory Committee on Water Pollution in its report to the National Resources Committee dated May 3, 1935. This committee recommended in part:

1. That powers and funds be granted to an appropriate federal agency to institute a coöperative program of investigation with legally constituted state agencies for such special studies as appear desirable, and particularly for the development of appropriate standards for water use and control.
2. That in order to stimulate the construction of pollution abatement works, funds for the purpose be made available by the federal government to local public and private agencies on a grant-in-aid or loan basis.

Although New York is one of the 8 states which have fairly satisfactory anti-pollution laws, trained personnel, and reasonably adequate funds for control of stream pollution, the progress made in the elimination of stream pollution was far from satisfactory until federal aid was made available for the financing of sewerage projects. This is evident when we consider the fact that

the population served by sewage treatment plants under construction or authorized with federal aid during the past 3 years is greater than the population served by all the treatment plants constructed between 1903 and 1933.

Considering the enormous funds that all of the municipalities in the state have expended for home and work relief during the past 4 years, very few, if any, will be able to undertake costly non-liquidating projects of this kind without federal aid.

In my opinion very few new sewage treatment plants will be constructed in New York State outside of the New York metropolitan area during the next 10 years unless such aid is provided, and I believe that the same will be true in the other states of the Union. Whatever our opinion may be regarding federal aid in financing local projects, the fact remains that unless such aid is forthcoming in the form of loans or grants there will be little progress in the elimination of stream pollution in the United States for a considerable time to come.

A Menace to Health

OBESITY, seldom in itself a serious health problem, seems to be a matter of great concern to many. Far too many of the obese seem willing to "try anything once" that offers an easy way to reduce weight. The great number of proprietary "fat reducers" offered to the public gives eloquent testimony of this.

During the war those engaged in the manufacture of explosives suffered much from various poisonings. It was noted that those exposed to dinitrophenol when poisoned, in addition to other symptoms, lost weight remarkably. In recent years an effort was made to use this chemical in a "safe" dosage, yet in sufficient amount to reduce weight.

The experience of the past two or three years should be enough to prove to the profession that it is very doubtful if there is any such thing as a "safe" dosage for this dangerous drug. The dangers attendant upon its use, even in the hands of physicians, are so great that its uncontrolled sale to the laity seems actually criminal. Canada has forbidden its sale except on a physician's prescription. Its sale is similarly restricted in England. Germany has issued official warnings as to its use. But in this country, if not "misbranded," it seems difficult to control its sale. It *will* accomplish reduction in weight, so technical "misbranding" is hard to prove. In Cleveland, only by mutual agreement among pharmacists, probably largely to protect themselves from possible damage suits, has sale of this drug in proprietary form been stopped. The Council on Pharmacy and Chemistry of the A.M.A. a year ago refused to include this drug in the N.N.R. for ample reasons given in its report.[1] . . .

The moral? Even if we have no law which can be invoked to protect the public in such cases as this, we owe it to ourselves as physicians to do all in our power to safeguard our patients from exposure to the hazards involved in the use of such dangerous drugs of such questionable value.—A. G. Cranch. *Bull. Acad. Med.* Cleveland, 10, 9 (Sept.), 1936.

Need for Training Facilities for Public Health Personnel in the Western States*

FRED T. FOARD, M.D., F.A.P.H.A.

Surgeon, U. S. Public Health Service, San Francisco, Calif.

THE demand for personnel trained in the field of public health has seen a steady growth since the early part of the present century. Among the public health movements inaugurated during the first two decades of the century and which played important rôles in the development of the public health field as we now know it, may be mentioned the nation-wide fight against tuberculosis inaugurated by the National Tuberculosis Association; the inauguration of community nursing service by the American Red Cross; the hookworm campaigns carried out throughout the south by the Rockefeller Foundation, and studies and demonstrations in rural sanitation carried out by the U. S. Public Health Service with the view of controlling typhoid fever and kindred diseases through the improvement of environmental sanitation. Also, the conduct of mosquito eradication programs in the prevention of yellow fever and malaria may be mentioned as individually conducted public health programs to prevent specific diseases. Each of these individually conducted programs served an important part in bringing the people of the country to realize that public health is something which no progressive community should be without and without which no community can be expected to continue to progress.

With this realization on the part of the public there developed a new era in health administrative practice. Appropriations for state health departments increased to provide for the maintenance of sanitary engineering service to include the development of safe water supplies, the installation of sanitary sewerage systems, the improvement of housing conditions, etc., as engineering problems requiring technical training. The addition to state health organizations of divisions of epidemiology, industrial hygiene, and for the promotion of maternal and child hygiene, were developments within the present century which have increased the demand for public health personnel trained in the different branches of health work.

Out of this expansion of state health service there came the development of full-time local health departments organized to carry out intensive health promotional programs on a city, county, or district-wide basis. With this expansion of full-time local health service there was a still greater demand for health officers, nurses, and sanitary

* Read before the Western Branch American Public Health Association at the Seventh Annual Meeting in Vancouver, B. C., June 26, 1936.

officers, but for whom no training facilities were available until after the World War.

Facilities for training nurses in public health work have been available in many states for a decade or more. Also the excellent public health schools organized at Hopkins, Harvard, and Yale a number of years ago have furnished trained public health officers, the most of whom have been placed in staff positions with our state departments of health. On the other hand, training facilities for supplying personnel for local health departments have not kept pace with the comparatively rapid development which has taken place in this field during recent years. As a result, our state health officers have been compelled to accept personnel for the administration of local health service who have been without either practical or theoretical training in health work. Many of these health workers have rendered excellent service, yet there are many others who have come into the public health field through the so-called " spoils system " which, unfortunately, is still being practised in many communities and doubtless will continue to be practised in the selection of health workers until health administration has reached that state of efficiency when positions in the field of public health will no longer be considered convenient berths for back-slapping vote-getters, or for the worthy aged who have spent long and active lives in other lines of endeavor. As health workers, we are therefore confronted with the obligation to bring public officials having appointive power to realize that executive and staff positions in the public health field are positions in which a very definite responsibility to the people is imposed. Until this is done the public health movement will continue to experience that lack of interest on the part of the lay public which will mean failure or, at best, very slow progress. Therefore, it should be the aim of every conscientious worker in the field of public health, also of every citizen who believes in the principles of preventive medicine, to overcome this far too prevalent attitude of indifference to efficiency which is met with in many appointive officers and their appointees.

Foreseeing the necessity for placing the public health field on a higher plane of efficiency, the Committee on Administrative Practice of the American Public Health Association several years ago recommended certain qualifications which should be required of personnel entering the field of public health. In 1935 the Committee on the Qualifications of Local Health Officers of the State and Territorial Health Officers Conference recommended certain qualifications which should be required by all state health officers of personnel entering public health work for the first time.

With funds allotted to provide for training personnel under the provisions of the Social Security Act, we now have an opportunity to bring into the public health field a group of workers who are basically better fitted to perform the duties which will be expected of them after they have received special training in their selected lines of public health work. If care is exercised—and certainly it should be exercised—in the selection of those nominated for public health training, and equal care is exercised by training centers in accepting students for matriculation, there is no question but that funds expended for this purpose will in the future return large dividends on the investment made for training public health workers. Not only will the individual receiving such training be equipped to render more efficient service in his special line of endeavor, but the whole public health movement will, within a few years, be given a stability which it has never before known.

On the other hand, there are many efficient public health workers who are now, and have for many years past, been engaged in public health work, and whose training has been confined to practical experience. They have attained success through hard work and the application of common sense principles to the solution of problems met with from day to day. This type of health worker has been largely responsible for progress made in the development of the nation-wide public health movement, and they should be given an opportunity to receive training under the provisions of the Social Security Act. Many of these workers are anxious for training and to meet this need, also the need for intensive training for those who are just entering the public health field, short courses are being organized to give intensive training over a period of 3 to 4 months, to health officers, public health nurses, and sanitarians. Such a school has been conducted at least once each year since 1927 at Vanderbilt University in Nashville, Tenn. Since funds became available under the Social Security Act, and in order to meet the demands for trained personnel, similar courses have recently been organized at the Universities of North Carolina, Michigan and Kentucky, for health officers and sanitary officers. Other short courses for public health nurses are being conducted by many public health nursing schools approved by the National Organization for Public Health Nursing.

In the far West we have ample facilities for training public health nurses at established public health nursing schools conducted by the Universities of California, Oregon, and Washington; but we have no permanently established facilities at the present time for giving intensive courses of training to health officers or sanitarians. Doubtless, such a school will be organized in connection with the University of California and will begin activities when the fall semester opens in August of this year. The school will be supported through tuition paid by the several states from Social Security funds and through a subsidy paid by the states on a per capita basis or by a subsidy paid by the U. S. Public Health Service to the school concerned through the state department of health of the state in which the school will be located. Plans are now under way for the organization of this school. That such a school, organized in the far West to serve the West, is urgently needed, is apparent for several reasons:

1. There are no training schools west of the Mississippi to which health officers or sanitarians may be sent for intensive short courses, and there is no school from which certificates in public health or degrees in public health may be obtained by medical officers who desire to take a course of training over one or more years.

2. There are many public health problems peculiar to the western states which do not exist as problems in the eastern states. Where the control of typhoid fever or the dysenteries or hookworm is a problem of first importance to the public health worker of Alabama, or Mississippi, or West Virginia, the control of Rocky Mountain spotted fever or tularemia is of equal importance to the health worker of Montana, or Idaho. Also, it is just as important that a health department in California be in a position to carry out or to direct rodent control measures as a means of preventing outbreaks of bubonic plague as it is for a health department in Louisiana or Florida to be engaged in mosquito eradication measures as a means of controlling malaria. Proper supervision of the great canning industry on the Pacific Coast is an important duty of the sanitarian of that area, whereas that particular phase of public health work is, by way of comparison, of minor importance to the sanitarian of the New England States. Thus we see the principal problems of the public health worker of the far West are in a sense peculiar to the far West, and for that reason if for no other reason, training facilities are urgently needed in the western part of the country to serve the western states.

3. On the other hand, let us consider the demand for trained public health workers in

the western states. The 11 western states comprising the 5th Engineering District of the U. S. Public Health Service, including New Mexico, Colorado, and Wyoming, and all states west to the Pacific Coast, cover a total area of more than 1,178,000 square miles and had a total population of less than 12 million people in 1930, or an average of only about 10 people to the square mile. This within itself is a problem peculiar to the western states. The land area of the largest county in each of these states varies from 4,800 square miles in Colorado to more than 20,000 square miles in California, with both Arizona and Nevada having counties with land areas above 18,000 square miles. Of the total of 400 counties in the 11 far western states, 42 have an area of more than 5,000 square miles; 38 have a population of 1 or less per square mile; 194 have a population of 5 or less per square mile, and in the entire area exclusive of California there are only 74 towns or cities having a population of over 10,000. Obviously these sparsely settled counties cannot individually afford now, nor will many of them ever be able to afford the maintenance of adequate health service.

PRESENT STATUS OF FULL-TIME COUNTY HEALTH SERVICE

In the entire area at the present time only 37 of the 400 counties are maintaining full-time county health service organized to serve the people of individual counties. In the state of New Mexico, however, 10 health districts have recently been established to provide a minimum health service to the people of all counties of that state. By the establishment of these districts under a state law providing that all counties must financially participate in the maintenance of a local health service as a part of one of the 10 districts set up under the state law, New Merico has taken the lead of all states in the West, if not in the entire nation, in solving the problem of furnishing a full-time and reasonably adequate health service to the people of the most remote areas as well as to the people of the more thickly populated areas of the state. While it is impossible to mention the details of the New Mexico District Health Law in this paper, other states contemplating the organization of local health service for sparsely settled counties would do well to look carefully into the law under which the district health service is being administered in New Mexico.

FUTURE DEVELOPMENT

By a recent survey of the 11 western states we are advised that plans have been completed for the establishment of 22 full-time county health units which will serve individual counties and will become operative as soon as trained personnel is available. Also, plans are under way for the organization of 37 new health districts which will furnish full-time health service to 103 counties. In several states it is expected that these district health units will in the beginning be maintained entirely from state funds or from federal funds made available to the states. In some instances it is planned that the counties comprising each district will be required to assume, according to population, their proportionate share of 10 per cent of the maintenance cost of the district after the first year and an additional 10 per cent each year thereafter until at least 50 per cent of the total cost is borne from local funds. Where legislation does not require local financial participation it is believed that this or some similar method will be the only means by which reasonably adequate health service can be furnished for the sparsely settled counties of the West.

To furnish needed personnel for new county or district health departments, now planned but not in operation, will require, by conservative estimate, more than 200 public health nurses, approximately 60 health officers, and at least 100 sanitary officers or sanitary engineers for local health departments. There will in addition be needed a considerable number of trained laboratory

technicians and at least some clerks trained in vital statistics work. County health units now established are already beginning to increase their personnel, and it is expected from the established units there will be an additional demand upon training centers for refresher courses for personnel now employed as well as for training personnel to be later employed.

In conclusion, I am pleased to say that the attitude of the state health officers of the far western states in the matter of selecting only the best trained personnel available for positions in both state and local organizations, has been particularly encouraging. So far, I know of no instance where staff positions in state health organizations have been filled by personnel untrained or inexperienced in the particular line of work to which they have been appointed.

On the other hand, however, I do know of a number of positions which are as yet unfilled because qualified personnel is not available. In some instances state health officers who formerly were compelled to approve for local public health positions inexperienced personnel recommended by local officials, have refrained from filling these positions or have refused to start local health departments which might now be under way except for a lack of suitable personnel.

This attitude is one which is highly commendable and which if continued will prove in the long run to be of inestimable value to the public health movement from both a state and a national standpoint. It is far better that the states carry over unexpended funds from one year to another, or if necessary return unexpended balances to the state or United States treasuries than it is to expend local, state, or federal money for so-called health service which will prove to be a discredit rather than a credit to the state public health programs. In other words, the public health leaders of the country are, in a sense, "on the spot." With the wise expenditure of funds made available for public health work under the provisions of the Social Security Act, and from local sources, there is every reason to believe that the public health movement will rapidly expand to serve a much greater proportion of the total population of the country, and that health work in general will advance in the esteem of the public at large.

It remains to be seen how effectively these funds will be expended, and it is certain that no portion of your Social Security allotment can be more efficiently expended than in providing, in so far as it is possible to do so, the best available training for those who are now or are expected to be placed in public health positions.

Better training for all classes of health workers means greater efficiency and, in the long run, efficiency will prove to be the best sort of politics. Anyhow, upon our ability to get the greatest possible return upon the investment made in public health promotional work will depend the continued support of our federal, state, and local governments.

Staphylococcus Bacteriophage Toxoid

An Improved Staphylococcus Antigen

AUGUST HOLM, Sc.D., JOHN F. ANDERSON, M.D., F.A.P.H.A., AND GEORGE F. LEONARD, M.D.

Biological Laboratories, E. R. Squibb and Sons, New Brunswick, N. J.

THE soluble exotoxin of *Staphylococcus pyogenes* is converted easily into toxoid. Active immunity in laboratory animals and in human beings may be produced by injection of this toxoid. The endotoxin of the staphylococcus, however, though it is probably an important factor in staphylococcus infections, has received little attention of late.

The antitoxin produced by the immunization of horses with staphylococcus toxoid and toxin is used in generalized staphylococcus infections. However, in certain cases of staphylococcemia in adults and adolescents, the administration of antitoxin, even intravenously, was of no effect.[1] The failure of the antitoxin to exert a favorable influence has been explained by the undue delay which frequently takes place before the correct diagnosis can be made. Upon the probable assumption that the mechanism of action of staphylococcus antitoxin in systemic staphylococcus infections is analogous to that of diphtheria antitoxin in diphtheria, it has been suggested that the staphylococcus antitoxin, due to the delay in its administration, is unable to repair the damage already done.

While these explanations no doubt are correct in many cases, some importance also may be ascribed to the absence of antibacterial antibodies in the staphylococcus antitoxin used. For instance, it is not impossible that a lack of bacterial antigen in the toxoid underlies failure of response to toxoid injections in some refractory cases of localized staphylococcus infection. Furthermore, clinical experience has been encouraging with antibacterial serums produced by the immunization of horses with live, killed, or lysed microörganisms, such as pneumococci, meningococci, and streptococci.

The therapy in different infections should not be based too closely upon existing analogies in certain directions, but all the pertinent factors, especially when dissimilarities exist, should receive due consideration. Just because the diphtheria bacillus and *Staphylococcus pyogenes* both produce an exotoxin, it does not necessarily follow that the activity of the two organisms is equally well neutralized by their specific antitoxins. If the invasiveness of the organisms, as in this case, happens to be very different, as shown by the extremely rare findings of diphtheria bacilli in the blood stream or cerebrospinal fluid,[2] in contrast with the relatively frequent occurrence of staphylococcemia and staphylococcus meningitis, prophylactic and therapeutic preparations should be made and administered with this difference in view.

Staphylococcus vaccines, stock and autogenous, have been used for a long time in the prophylaxis and treatment of localized staphylococcus infections;

and in a proportion of the cases they have proved of definite value. Staphylococcus bacteriophage is still used, although less extensively than a few years ago, and of late staphylococcus toxoid has been employed successfully. Since vaccines, bacteriophage solution and toxoid embody, as a group, the endo- and exotoxic antigens of *Staphylococcus pyogenes*, the character of the immunity produced by each of these therapeutic agents is probably distinctive. If, now, an antigen could be prepared which contained both endo- and exotoxic principles, the immunity produced should be more complete and presumably more effective than a strict antibacterial immunity or a specific antitoxin immunity.

Furthermore, if the antitoxin used in the treatment of general systemic staphylococcus infections also contained antibacterial antibodies, the administration of such a preparation would be more in accordance with the known characteristics of *Staphylococcus pyogenes* than the use of the specific antitoxin alone. These considerations have prompted an attempt to prepare a staphylococcus toxoid which would contain endotoxic as well as exotoxic principles of lysed staphylococci from many different strains.

Several methods for lysis of bacteria are available, but lysis by bacteriophage seemed the most promising, since bacteriophage solutions contain all the bacterial proteins set free by lysis. By this method denaturation by heat or by other treatment is avoided, and the endo-antigens liberated are presumably more like the bacterial elements arising from parenteral digestion of staphylococci which have invaded the host. The bacteriophage solutions may therefore be considered "super vaccines" containing all the chemical constituents of the staphylococci.[3] Larkum states,[4] that staphylococcus bacteriophage is an antigen of toxoid character, since it is devoid of hemolytic and dermonecrotic activity, is innocuous to rabbits, and will produce antitoxin which neutralizes the toxic properties of staphylococcus toxin.

EXPERIMENTAL

In order to avoid dilution of both the toxoid and the bacteriophage solution of the staphylococci, if a mixture of these products were prepared, the bacteriophage solution should either be made in the toxin for later conversion into toxoid, or the toxin should be made, using the bacteriophage solution as a medium. Bacteriophage solution could not be made in the toxoid owing to the presence of formalin. Since toxin production, however, was much inferior when prepared in bacteriophage solution as compared to the regular medium, whereas good growth, with subsequent clearing with bacteriophage, was obtained in staphylococcus toxin, the following steps were fixed upon for the preparation of this polyvalent staphylococcus antigen:

1. Preparation of the staphylococcus toxin, as described below
2. Berkefeld filtration of the toxin
3. Inoculation of the Berkefelded toxin with a pooled culture of six different strains of staphylococci together with an adapted staphylococcus bacteriophage
4. Centrifugation, if necessary, after clearing of the culture by the bacteriophage
5. Addition of formalin and merthiolate
6. Incubation for conversion of the toxin into toxoid, and for detoxification of possible endotoxins
7. Berkefeld filtration and testing for innocuity and antigenicity in the usual manner

PREPARATION OF STAPHYLOCOCCUS TOXIN

The staphylococcus toxin was prepared according to the method previously described by Leonard and Holm,[5] and had a strength of 3,000 m.h.d. and 2,500 m.d.n.d. per c.c., while 0.25 c.c. injected intravenously killed rabbits weighing 2.1 kg. in 3 minutes.

PREPARATION OF ADAPTED BACTERIOPHAGE

Staphylococcus bacteriophage, as prepared at the Squibb Biological Laboratories, was active toward all the pathogenic strains of staphylococci used in this work—but to different degrees. Four strains of *Staphylococcus aureus* and two of *Staphylococcus albus* were employed. By serial transfers over about 2 months the bacteriophage was adapted to such an extent that a dilution of 10^{-6} cleared a culture when incubated 24 hours at 37° C. and another 24 hours at room temperature.

PREPARATION OF BACTERIOPHAGE TOXOID

After Berkefeld filtration of the toxin, it was divided into three parts, of which one part served as a control, the second was converted into bacteriophage toxoid, while the third part was made into staphylococcus toxoid.

One liter of the toxin was inoculated with 1 c.c. of undiluted pooled staphylococcus culture and with 1 c.c. of a 1:1,000,000 dilution of the adapted bacteriophage; subsequent incubation took place for 24 hours at 37° C. and for 24 hours at room temperature. The staphylococcus cultures were the same strains which had previously been employed in the preparation of the toxin. Growth was profuse, and partial clearing started 7 hours after inoculation. After the incubation at room temperature, the liquid was perfectly clear and centrifugation consequently was not necessary. Hemolytic and dermonecrotic tests showed that no diminution of toxicity had taken place. Controls were made with untreated toxin similarly incubated. To untreated toxin and bacteriophage toxin was added formalin to make a concentration of 0.35 per cent and merthiolate to 1:10,000. The bottles were placed in the incubator at 37° C. for 17 days, when detoxification was complete. The usual tests for innocuity [5] were made on these final products. Since staphylococcus bacteriophage toxoid contains both endo- and exotoxic principles in solution, the combined antigen may be designated Ambo-toxoid.

The principle outlined for the preparation of the improved staphylococcus antigen, might be utilized also with other microörganisms which produce both exotoxin and endotoxin. In this manner it may be possible to obtain more effective antigens, both for active immunization of human beings, and also for the production of more potent antibodies in the horse or other animals.

IMMUNIZATION OF RABBITS

By animal inoculations the antigenic potency of staphylococcus bacteriophage toxoid was compared with that of toxoid derived from the same staphylococcus toxin, and with that of a fresh bacteriophage solution prepared in the same medium that had served for the production of the bacteriophage toxin. These preparations were tested in three experiments on different lots of rabbits.

Experiment 1—Fifteen albino rabbits, ranging in weight from 2,700 to 3,100 gm., were bled from the marginal ear vein, and the serum of each was tested by the hemolytic method for presence of "natural staphylococcus antitoxin." Lots of 5 rabbits were injected intravenously with 3 c.c. respectively, of staphylococcus toxoid, bacteriophage toxoid, and of bacteriophage solution. One week later the rabbits were bled, the serum was tested for staphylococcus antitoxin, and the animals were reinjected with 5 c.c. of their several preparations. After 1 more week a final bleeding was taken, and the serum again was tested for staphylococcus antitoxin. The results are recorded in Table I.

If rabbit No. 86 in Table I is eliminated on account of an initial high "normal" antitoxin titer, and if rab-

bits Nos. 78, 83, and 88 in the same table are disregarded on account of intercurrent disease, it seems evident that the bacteriophage toxoid rabbits showed a considerably better immunity response than the rabbits injected either with staphylococcus toxoid or with bacteriophage solution. The average antitoxin titers, if rabbits Nos. 86 and 83 are eliminated, are 2 units per c.c. of serum from the animals immunized with staphylococcus toxoid, 4.5 units for the rabbits injected with bacteriophage toxoid, and 0.85 units for the animals with bacteriophage solution.

Experiment 2—The rabbits were 15 brown animals, weighing from 2,100 to 2,400 gm. This was a duplicate of Experiment 1, except that 1 week after the last bleeding each animal received an intravenous injection of 5 billion staphylococci from a 16 hour pooled broth culture of the same virulent strains used throughout this study. The results, collected in Table II, are of the same order as those of Table I in that the highest antitoxin titer occurred in the serum from rabbits immunized with bacteriophage toxoid. The mean titer for this group was 10 units, for the toxoid group 6.2 units, and for the bacteriophage group 0.66 units of antitoxin per c.c. of serum.

It has been claimed that resistance in bacteremias caused by the staphylococcus depends upon the titer of serum antitoxin, but other factors may also be of importance as indicated by the results of the intravenous injections of live virulent staphylococci into the immunized animals of this group. Although the rabbits immunized with staphylococcus toxoid all showed considerable antitoxin production, none of them survived 10 days after the injection of the live organisms. Of the bacteriophage toxoid rabbits, No. 12, with 5 units, and No. 14, with 13 units of antitoxin survived, while the 3 other animals with 13, 11, and 9 units respectively, died. But of the animals injected with bacteriophage solution, which exhibited only a negligible capacity to excite antitoxin production, one rabbit, with only 0.08 units of circulating antitoxin per c.c. of serum, survived injection of the live culture for 3½ days, while another rabbit, with 0.64 units of antitoxin, survived 7 days.

Experiment 3—In this experiment 30 gray rabbits, weighing from 2,200 to 2,600 gm., were immunized in the same manner as in the other two experiments. Two of the animals died from intercurrent disease early in the test. In order further to test the supposition that circulating antitoxin is not a measure of resistance against live virulent staphylococci, the 28 survivors were injected intravenously, 1 week after the last bleeding, with 5 billion staphylococci from a 16 hour pooled broth culture of the same virulent strains that had been used in all of the previous experiments. The results are given in Table III.

As in the first two experiments the antitoxin titers are considerably higher for the rabbits injected with bacteriophage toxoid, than for the animals that were injected with staphylococcus toxoid or with bacteriophage solution, the group averages being respectively 6.9, and 4.0, and 0.49 units. The intravenous injection of the 5 billion virulent staphylococci caused the death in 72 hours or less of all rabbits immunized with staphylococcus toxoid, irrespective of antitoxin titer, while 6 out of 9 rabbits survived in the bacteriophage toxoid group, and 3 out of 9 animals survived in the bacteriophage solution group.

When the data for the 3 experiments are combined, it is found that the mean antitoxin titers of 18 rabbits, after inoculation with the 3 antigens were: staphylococcus toxoid, 4.3 units; bacteriophage toxoid, 7.3 units, and bacteriophage solution, 0.56 units.

Of 15 rabbits which were injected with live, virulent staphylococci after their inoculations with staphylococcus toxoid, none survived more than 9 days, while 11 died within 48 hours. Of 14 rabbits immunized with bacteriophage toxoid, 8, or 55 per cent, survived the later staphylococcus injection. Finally, of 12 rabbits inoculated with bacteriophage solution, 3, or 25 per cent, withstood the injection of live staphylococci.

SUMMARY

1. A staphylococcus toxin containing lysed microörganisms was prepared by inoculating a staphylococcus toxin after passage through Berkefeld filter with bacteriophage and a staphylococcus culture. After lysis the resulting bacteriophage toxin was converted into toxoid by formalin and incubation at 37° C. as in the production of staphylococcus toxoid. The bacteriophage toxoid was tested for innocuity, and its antigenicity was compared to that of staphylococcus toxoid and of bacteriophage solution.

2. The antitoxin titers of rabbits immunized with the bacteriophage toxoid were consistently higher than the titers resulting from the immunization by staphylococcus toxoid or bacteriophage solution.

3. Intravenous injection of two-thirds of the immunized rabbits each with 5 billion live virulent staphylococci was fatal to all of the animals immunized with staphylococcus toxoid, whereas 55 per cent of the animals injected with bacteriophage toxoid survived, as did 25 per cent of the animals injected with bacteriophage solution.

4. Survival of immunized animals that have been injected later with live virulent staphylococci apparently does not depend upon the amount of serum antitoxin present.

5. It is probable that the procedure outlined above for the preparation of bacteriophage toxoid may be utilized with other microörganisms, especially those that yield endo- as well as exotoxins, and which may be lysed by bacteriophage. Thus it should be possible to obtain more effective antigens for active immunization of human beings, as well as for the production of more potent antibodies in the horse or in other animals.

Diphtheria Immunization in Newark, N. J.

HEALTH PROGRESS[1] for September, 1936, gives a very interesting report on the control of diphtheria by immunization in Newark, N. J. Toxin-antitoxin was supplied free as early as 1922, and by 1926, somewhere between 10 and 20 per cent of school children and a smaller proportion of preschool children had been immunized. In 1926 there were 409 cases with 21 deaths, whereas for 11 years previously there had been an average of 1,000 cases and 50 deaths per year. There were still from 70,000 to 80,000 unprotected school and preschool children, and in 1927 an upward swing took place, with 696 cases and 62 deaths; 1,364 cases with 95 deaths in 1928; and 1,717 cases with 96 deaths in 1929. An active campaign was begun, and by 1930, 80 per cent complete immunizations had been done. At present 95 per cent of the children have been immunized, and in some schools, 100 per cent immunization has been reached.

The results are striking and inspiring. In 1930, cases and deaths dropped to 873 and 47 respectively. In 1931 there were only 223 cases with 16 deaths; in 1932, 70 cases, with 2 deaths; and in the 3 succeeding years, 21, 10, and 12 cases respectively, with 1 death for each year. In the most recent 2 full years there have been 18 cases only with 1 death. This is a wonderful record for immunization, and should inspire other health officers to pursue this line of protection.—M.P.R.

Expenditures in Certain Cities for Selected Health Services

THE cities entered in the Health Conservation Contest compete with each other in 6 groups based on population. These groupings are retained in the table below.

The data contained in this table have been compiled by the Sub-Committee on Current Health Department Practices of the Committee on Administrative Practice of the American Public Health Association. The information has been obtained from schedules submitted in the annual City Health Conservation Contests. The per capita expenditures are based on 1930 U. S. Census Bureau population figures for each of the 6 years portrayed.

The health services covered include: Administration; Vital Statistics; General Sanitation; Milk, Meat and other Food Control; Acute Communicable Diseases; Tuberculosis Control; Venereal Disease Control; Child Hygiene including Maternal, Infant, Preschool, and School Hygiene; Public Health Nursing, and Laboratory Services.

All expenditures for hospitalization, institutional care, medical relief, garbage collection and disposal, and capital expenditures and deficits have been *excluded*. In school hygiene, board of education expenditures for medical school inspection and school nursing have been *included* while expenditures for physical education and health instruction by teachers have not.

NOTE: This article is based on the Report of the Sub-Committee on Current Practices of Health Departments of the Committee on Administrative Practice. The members are: Joseph W. Mountin, M.D., *Chairman*, E. L. Bishop, M.D., Henry F. Vaughan, Dr.P.H., Allen W. Freeman, M.D., George T. Palmer, Dr.P.H., John L. Rice, M.D., W. Frank Walker, Dr.P.H., and C. M. Derryberry, Ph.D.

* Group I—Cities of over 500,000 population
" II—Cities of 250,000 to 500,000 population
" III—Cities of 100,000 to 250,000 population
" IV—Cities of 50,000 to 100,000 population
" V—Cities of 20,000 to 50,000 population
" VI—Cities under 20,000 population

NOTES

1. Exclusive of WERA.
2. Public health and hospitals.
3. Public health.
4. Health Department only.
5. Budget.

Averages for the entire group for each year have not been published because of the fact that the number of reporting cities varies so greatly from year to year. It may be of interest, however, to know that among 79 cities reporting for a 5 year period, the average per capita expenditure in 1930 was 86.5 cents; in 1931 it was 90.1 cents; in 1932, however, it dropped to 82.9 cents; while in 1933 it dropped still further to 73.3 cents; but in 1934 it rose to 76.6 cents. Although figures for 1935 are not as yet available for a comparable group of cities, indications are that the average per capita health expenditure was higher in 1935 than in 1934.

Future of Maritime Quarantine in Canada*

J. J. HEAGERTY, M.D.

Department of Pensions and National Health, Dominion of Canada, Ottawa, Can.

IN order to evaluate future maritime quarantine activities, the problem should be considered from the standpoints of past experience and present-day public health knowledge. Quarantine was officially imposed for the first time in Canada on October 20, 1721, with the object of preventing the entrance of plague into the country. In the preceding year, plague was epidemic in Marseilles, 30,000 people having died of the disease; and as vessels were constantly plying back and forth between Mediterranean ports and Quebec, which was then the center of French Canada, de Vaudreuil, the Governor, and Begon, the Intendent, introduced the following somewhat drastic quarantine regulations. Literally translated from the French they read:

Captains or masters of vessels, bark or brigantine, from all Mediterranean Ports or which touched there, shall anchor in the stream off Isle aux Coudres. There, those who have cannon or swiveling guns shall fire three shots a quarter of an hour apart.

Those who have no cannon nor swivel guns shall fire three musket shots, also at an interval of a quarter of an hour apart.

One should also fly the distress signal. The same signal shall be repeated at intervals of two hours until such time as those whose duty it is to board the vessels will be cognizant of their arrival. It was forbidden to send small boats ashore, or to permit any member of the crew or passenger to disembark and communicate with any inhabitant of the colony. Corporal punishment was provided for the captain, master and those who went ashore. It was strictly forbidden to discharge cargo. An order was in force to burn any such cargo on the spot where found without further formality or judicial procedure.

The following list of questions was to be answered by the captain:

1. From what port does the vessel come?
2. At what ports did it touch on the voyage?
3. Was there infectious disease in any of the ports?
4. Were there any sick on board during the passage?
5. Were there any deaths?
6. How many?
7. With what disease?
8. Are there any sick on board at present?
9. How many?
10. What disease?

These quarantine regulations were revoked on June 19, 1724. If one compares the present-day list of questions submitted to captains of vessels undergoing quarantine inspection with that of 1721, it will be found that they do not differ essentially. Although this was the first occasion that quarantine was officially introduced, it was customary at an earlier date for the authorities at the port of Quebec to detain ships on which there was sickness until passengers and crews were examined by physicians.

* Read before the Conference of State and Provincial Health Authorities of North America at the Fifty-first Annual Meeting in Vancouver, B. C., June 22, 1936.

Soeur Francoise Juchereau, the historian of l'Hotel-Dieu de Quebec said:

> In the year 1710 a vessel named the Belle Brune arrived here (Quebec) coming from the Islands (West Indies). We suspected it of being infected with plague because four or five men were dead in less than twenty-four hours. We sent them surgeons to visit the sick and who, being satisfied that there was no danger to the community, they were permitted to disembark and we received from the ship many sick in our hospital, all of whom suffered with a burning fever during many weeks from an unknown sickness, but very dangerous by the ravages which it caused in the colony. Experience has taught us that it was the Mal de Siam (disease of Siam) that the Oriflamme brought to the Islands (West Indies) many years ago, and which has not left the country (West Indies) since that time.

"Mal de Siam" was the name given to yellow fever and it is of interest in passing to note that on account of the prevalence of this disease at the ports of New York and Philadelphia, Canada imposed quarantine against them in the year 1799 and again in the years 1802 and 1805.

Anticipation of the introduction into Canada of cholera, which prevailed in Europe in 1831, was the signal for extraordinary quarantine activities in the year 1832. Quarantine was established in that year at Grosse Isle in the St. Lawrence under the control of the military authorities, and all vessels proceeding up the St. Lawrence to Quebec were obliged to undergo quarantine. Two cannon placed at a strategic point were part of the quarantine equipment. Regulations similar in nature were introduced by New Brunswick, Prince Edward Island, and Nova Scotia. In spite of these precautions, cholera found its way into the country and thence into the United States with what disastrous result we know. In spite of quarantine measures, cholera was introduced by shipping and became epidemic in Canada in 1832, 1834, 1849, 1851, and 1854; and typhus was epidemic in 1847 and 1848. With the exception of influenza, these are the only occasions that contagious diseases were introduced into the country and reached epidemic proportions. Following the confederation of the provinces in 1867, a number of quarantine stations were established. Some of these have since been abolished. There are at the present time 4, namely, at William Head, B. C.; Grosse Isle, P. Q.; Partridge Island, N. B.; and Lawlor's Island, N. S. At all other maritime ports the customs officer acts as the quarantine officer. Should a case of quarantinable disease be discovered on board a vessel at one of these ports, the customs officer calls a physician, and the necessary quarantine measures are adopted. It should be noted that the number of vessels that call at these unorganized ports is negligible. If facilities are not available for handling a case of quarantinable disease at one of these ports, the vessel is directed to the nearest quarantine station.

Each of the above mentioned quarantine stations is equipped with a quarantine boat for the purpose of boarding vessels, a disinfection plant, detention buildings for contacts, and a hospital. The total hospital bed capacity of the combined stations is 241, and the detention bed capacity 1,946. In addition, there is a fully equipped laboratory.

Prior to the adoption of the International Sanitary Convention, signed at Paris on June 21, 1926, quarantine included minor infectious diseases. Under the Convention, it comprises only 5 diseases, namely, plague, cholera, yellow fever, typhoid, and smallpox. It is laid down in Article 14 that Signatories to the Convention undertake to maintain in their large ports and their surroundings sanitary services capable of applying the prophylactic measures laid down in connection with the quarantinable diseases above men-

tioned, and the Signatories are obliged to supply at least once a year to the Office International a statement of their sanitary organization. The Convention laid down the sanitary procedures to be followed in dealing with the quarantinable diseases when they are found aboard ship.

Article 15 states that any ship, whatever its port of departure, may be subjected by the sanitary authority to medical inspection. It is not obligatory to inspect all ships arriving at a port, although that is now the practice in many countries, including the United States and Canada. That much of this routine inspection is unnecessary, wasted effort, and futile, is well known.

It is stated that plague found its way into Quebec in the years 1710, 1718, and 1740, but a study of the meager records of those years leaves one very much in doubt as to the true nature of the epidemics. It is also claimed that 2 cases of plague were found in Vancouver and 1 in Victoria in 1906 and 1907. The cases in Vancouver were that of a young woman and a laboring man; while that in Victoria was a stevedore. All 3 recovered. During the summer of 1919, it was reported that 2 cases of plague occurred in a ship while on its way from Montreal to Bristol, the ship having sailed originally from Alexandria. The diagnosis was made in Liverpool. It has not been possible to confirm the diagnosis in any of these cases, but I think you will agree that the likelihood of plague being introduced by shipping today is rather remote, particularly in view of the extraordinary precautions that are taken to de-ratize vessels in all world ports.

The last time that cholera was brought to Canada was by a vessel which arrived in Halifax in the year 1871. Two men who were employed in coaling and watering the vessel contracted the disease, one of them conveying it to his family, 4 being infected and 2 dying. The widespread epidemics of cholera during the so-called cholera years in Canada were water-borne. The presence of cholera in a community today would not occasion alarm in view of the fact that practically all cities are possessed of modern filtration plants and water carriage systems.

No case of typhus has been found aboard ship at a Canadian port since 1915—21 years ago—and as immigrants from Europe to Canada are all deloused before embarkation, the probability of its occurrence is negligible.

We have not found a case of smallpox on board any vessel at any of the eastern ports of Canada since 1929, but cases of that disease are occasionally found on board vessels at the Quarantine Station at William Head, B. C. The compulsory vaccination of immigrants from smallpox infected areas prior to embarkation has reduced the probability of its occurrence among immigrants on board ship to a minimum, and the adoption of the smallpox immunity reaction in the case of contacts has likewise reduced the number of detentions.

Yellow fever has never been known to occur in Canada even during epidemics of that disease in New York, Philadelphia, and Baltimore, so that it need not be considered seriously from the standpoint of quarantine.

At the present time all vessels entering the maritime ports of Canada are obliged to undergo quarantine. They anchor in the stream, where they are boarded by the quarantine officer who examines both crews and passengers to ascertain if any of them is suffering from a quarantinable disease. Such examination, however, is made only from sunrise to sunset. Should the vessel arrive at night, crews and passengers are not examined, the word of the captain or doctor, as the case may be, being accepted without question. This

is an anomalous situation. If crews and passengers are not examined in the case of a vessel arriving at night, then we may ask why the necessity of examining those that arrive in the daytime. Moreover, practically all vessels now have wireless, and the quarantine officer knows the state of health of the vessel long before it has arrived, and the need for detaining a healthy vessel in the stream until the quarantine officer has given pratique is quite unnecessary.

Until the International Sanitary Convention was signed at Paris in 1926, it was customary in the case of an infected vessel to disembark, bathe, and disinfect the clothing and baggage of contacts. Disinfection of clothing and baggage has not been done since the Convention was signed and no ill results have followed. To carry out bathing, disinfection, and detention, large buildings and extensive equipment are necessary. These buildings and equipment have been standing idle for years. Staffs are required to maintain them, the expenditure is great and, in view of the exceptional occasion that quarantinable disease is found on board vessels, quite unjustifiable. Quarantine procedure needs to be modified. Park, in discussing quarantine in his *Public Health and Hygiene* published in 1928, has this to say about quarantine:

> The discoveries of the modes of transmission of yellow fever, typhus fever, and plague, and the development of public health activities by the Government, states, cities, and counties, all tend to minimize the necessity of doing more along purely maritime quarantine lines than to regard it as a palliative measure which is declining in importance in almost exact proportion to the effectiveness of public health measures in the ports of the world.
>
> Whenever a proper spirit of effective coöperation can be brought about on a permanent basis, wherein the Governments, port authorities, and shipping interests will unite on both business and public health principles to abolish maritime quarantine, except under extraordinary circumstances, such as epidemic or war conditions, the ordinary quarantine station, as we know it, need not be maintained.

After 25 years of experience in connection with maritime quarantine in Canada, I am firmly convinced that the boarding of all vessels by a quarantine officer in ports is quite unnecessary and should be discontinued or modified. There is no necessity to board all vessels that enter Canada, and I feel satisfied that the same thing applies to the United States. Quarantine inspection might well be confined to those vessels which report quarantinable disease on board, have had it on board during the voyage, or which come from an infected port. In Great Britain vessels included in the official list of infected ports and those that have infectious disease on board, or have had it on board during the voyage, are subject to quarantine inspection on arrival. Should a case of quarantinable disease be found on board, it is removed to hospital while the rest of the passengers are permitted to proceed to their destination, their names being forwarded to the public health officer who keeps such passengers under supervision. In this way, there is no need for maintaining large quarantine stations and staffs. We are told that the objection to this procedure in Canada, and I believe in the United States, is that we are not as highly organized from a public health standpoint as England, where there is central public health control, and that it would be impossible to obtain the coöperation of public health officials of provinces and states to supervise passengers from infected vessels who had been permitted to proceed to their destination. During 1934 only 2,065 vessels were boarded by medical officers in London, whereas 20,856 were inspected at that port for the purpose of ascertaining the presence of rats and for de-ratization. Keeping down the rat population in vessels is

considered of greater importance than the routine examination of passengers and crews for the presence of infectious disease.

The boarding station for the London area is at Gravesend and, in addition to a launch, comprises a hospital consisting of one ward of 8 beds, one of 4 beds, and 8 cubicles. There is also a smallpox hospital containing two wards of 4 beds each. Such are the quarantine facilities of the greatest of world ports at which thousands of vessels arrive annually.

In concluding this brief paper, I would recommend that the following modifications be made in Canadian quarantine procedure:

1. That quarantine inspection be confined to vessels that report quarantinable disease on board, or have had such disease on board during the voyage, or have come from an infected port so declared in the official list.
2. That vessels be boarded at the dock and not in the stream as at present. An exception may be made in regard to the latter only where boarding in the stream expedites quarantine procedure.
3. That the large, expensive, unwieldy and unnecessary quarantine stations be abandoned, substituting therefor small, modern units consisting of detention quarters for not more than 100 persons and a hospital unit on the cubicle system of half a dozen beds.
4. That de-ratization requirements as laid down in the Convention of Paris of 1926 be adhered to.
5. That laboratory facilities for bacteriological examinations be made by arrangement with the port health authorities.

I believe that such procedure will afford adequate protection to the country.

DISCUSSION

C. E. WALLER, M.D.

Assistant Surgeon General, U. S. Public Health Service, Washington, D. C.

I think, although I am not prepared to speak for the chief of our Division of Foreign Quarantine of the U. S. Public Health Service nor for the Surgeon General, that the Public Health Service would be interested in this proposal. In fact, members of the Surgeon General's staff have often discussed this very thing and have given a great deal of consideration to it.

I might be willing to go just a little bit further than Dr. Heagerty has gone and suggest that one of the most effective protection measures as far as the introduction of disease into the United States is concerned would be the development of adequate local health services at our seaports and along our borders.

As far as bubonic plague is concerned, I believe we can accomplish far more in protection by rat-proofing vessels and rat-proofing our seaports. The principal disease that the United States has to fear right now, so far as introduction is concerned, is yellow fever through airplane travel from South America. However, I think if we could persuade our state and local authorities to clean up this disease, even in our southern states, we need have no fear of introduction of yellow fever through airplanes.

RESOLUTION *

RESOLVED that the Conference of State and Provincial Health Authorities of North America endorse the recommendation contained in the address presented by Dr. J. J. Heagerty of the Department of Pensions and National Health of the Dominion of Canada, that the Maritime Quarantine Law be amended and its operation so simplified as to prevent the inconvenience to individuals entering Canada and the United States and particularly to reduce the expense to the shipping industry of the Dominion of Canada and of the United States.

* Adopted by the Conference of State and Provincial Health Authorities of North America, Vancouver, B. C., June 23, 1936.

Report of Committee on Transportation*

WALTER L. BIERRING, M.D.

Chairman of the Committee, and State Health Commissioner, Des Moines, Iowa

IN confining this report on transportation to the problem of air conditioning of trains, it is hoped to present certain sanitary aspects that may be of interest to this conference. I acknowledge my particular appreciation to Thomas R. Crowder, M.D., the *Consultant,* as without his valuable assistance this report would not have been possible.

As recently described by W. B. Coffey:[1]

> Air conditioning is a new term, comparatively recently adopted to describe synthetic or tailor-made weather, or the production of a comfortable atmospheric environment compatible with health in which to travel, work, and live. Air conditioning is concerned with the heating, humidifying, cleaning, circulating, and deodorizing of the air in winter, and the cooling, dehumidifying, cleaning, circulating, and deodorizing of the air in summer. With the elimination of discomfort it might tacitly be assumed that comfort will follow. To a large extent this is true in the present state of progress, but not completely so. Like other synthetic materials, synthetic weather is still inferior to the best that nature has to offer. No one has yet synthesized the weather of a perfect spring day, or of a glamorous sub-tropical moonlit evening.

Railroads since 1930 have equipped about 6,000 railway passenger cars with air conditioning devices for the following purposes, as stated by Dr. Coffey:

> 1. To improve health, safety and comfort of the passengers, especially in the summer vacation months, when the weather constitutes a real drawback to travel.
> 2. To produce as far as possible the general sense of physical well-being.

Two methods of air conditioning trains are now in general use. They are (a) mechanical cooling, and (b) ice cooling. The former uses a liquefied gas which cools a bin type radiator when evaporated within it; the latter uses water from melting ice, which cools a similar radiator when circulated through it. In each case the air is cooled by passing over the radiator. Regulation of the amount of cooling is accomplished by thermostatic control of the rate at which the expanding gas in the one case or ice water in the other is pumped through the radiator.

Variations of the above systems are found, one of which utilizes the evaporation of water in a very high vacuum to cool the radiator. From a mechanical and engineering standpoint installations vary widely. The Pullman Company has its own scheme, while the various railroads have utilized others which differ in many essential respects among themselves. All systems utilize recirculation of the air, requiring, therefore, a closed system of ventilation with some mixture of fresh and recirculated air in the ducts.

A description of one modern air-conditioning installation on trains is given in the March, 1935, issue of *Heating, Piping and Air Conditioning.* Thus, in describing the units of the Flying Yankee it is stated:

---

* Presented before the Conference of State and Provincial Health Authorities of North America at the Fifty-first Annual Meeting in Vancouver, B. C., June 23, 1936.

Each of the 5 passenger compartments of the new Flying Yankee is air conditioned, the compressors and condensers being housed beneath the floor of each unit, while evaporators and distributing fans are built into the roof above the vestibules. Fresh air is taken in through the doors into the vestibules and is then passed through filters where it is mixed with recirculated air in the proportion of 1:5. In the evaporator are located two combination cooling and heating coils, one at either side, and between these are two double blowers which project the conditioned air through centrally located grilles into opposite passenger compartments. The air is returned through grilles at either side of partitions at the roof. Here, too, are located removable and washable filter pads. Capacity of the refrigerating system is 5½ tons per car. In moderately cold weather the overhead coils heat the compartments with outside wall radiation. The entire equipment for the train weighs approximately 4,600 pounds complete.

With regard to the general mechanical requirements of railway air conditioning, the following remarks taken from the *Guide of the American Society of Heating and Ventilating Engineers* (14th ed., 1936, chapter 13, p. 258) may be stated:

The general principles of air conditioning as applied to buildings also apply to railway cars, but due to space and weight limitations and the severity of the service, equipment designed for stationary work in buildings is seldom suitable for car installations. Equipment for railway use must be safe, reliable, compact, light in weight, accessible for inspection and repairs, as nearly automatic in operation as possible, and have low initial operating and maintenance costs. To air condition a car properly, ventilating, filtering, heating, cooling, humidifying, and control equipment must be provided together with an adequate power supply. Air from the interior of the car is mixed with air from the outside and passed through the air conditioning unit where it is heated or cooled, humidified or dehumidified and delivered to the interior of the car through suitable ducts and grilles.

One of the important problems in connection with air conditioning of cars is that of ventilation. In non-air conditioned cars, ventilation is accomplished by exhaust fans, roof ventilators, and open doors and windows. This provides an ample supply of outside air and in addition a large amount of smoke and dirt which may be excluded in an air conditioned car.

An average car contains approximately 5,000 cu. ft. of air which is being contaminated by the occupants who are continually liberating heat, carbon dioxide, moisture, odors, and some organic matter from the breath, skin, and clothing. The heat and moisture can be removed by cooling and dehumidifying, but the others can be handled only by proper ventilation. In the average car from 2,000 to 2,500 cfm. of air should be delivered by the air conditioning unit.

Smoking rooms present a special problem. The cloud of smoke that usually hangs near the ceiling can be broken up by having the incoming air directed along the ceiling in all directions at a velocity somewhat higher than that used for the rest of the car. The air should be exhausted from the room by a fan or through a grille to the wash room or lavatory, to be exhausted to the outside through a ventilator.

Air conditioning of trains is based on comfort considerations. In this respect, a distinction between short and long hauls must be made. The human body requires from 1½ to 3 hours to become thermally adjusted.

Naturally, trains take on and drop passengers along route and the question as to whether adjustment for short or long haulage air conditioning at best is open to question.

It must be held in mind in dealing with air conditioning problems that personal acclimatization is an important factor. The sense of coolness on entering an air conditioned car is temporary and body adjustment will take place only after a period of time which will give a person a sense of comfort. Furthermore, as must be obvious, not all persons can be comfortable under one set of conditions. Age, sex, clothing, and state of health are factors to be considered.

Remarkable results are reported from the research laboratory of the Harvard School of Public Health on the application of ultra-violet rays to air conditioned chambers with a marked reduction of total bacterial count.

The essential principles of air conditioning are—

1. *Ventilation* — Defined as the process of supplying or removing air by natural or mechanical means to or from any space. Air conditioning is more

inclusive and implies the control of any or all the physical and chemical qualities of the air. Ordinarily, both ventilation and air conditioning are concerned with creating comfortable and healthful conditions in closed spaces.

2. *Physiological Reactions*—The importance of temperature, humidity, and air motion depends upon the influence which these factors exert on body temperature, comfort, and health. Our body temperature which is extremely constant, is dependent upon the balance maintained between its heat production and heat loss. This balance is automatically maintained in healthy persons by the action of the heat regulating mechanism. This is done by (1) regulation of internal heat production (chemical regulation), and (2) regulation of heat loss by automatic regulation in the rate of cutaneous circulation and the operation of sweat glands (physical regulation). On warm days, it is to be noted that the surface circulation of blood is increased; on cold days, the surface blood vessels contract and thus lie further beneath the skin which tends to insulate them.

3. *Acclimatization* — Acclimatization deals with man's ability to adapt himself to changes in air conditions. This is usually accompanied by an intangible psychological factor. Some persons appear to suffer intensely in a room with windows closed although atmospheric conditions generally may be quite comfortable. Perhaps the best example of acclimatization is our adaptability to winter and summer conditions of comfort. Thus, in summer a temperature of 68° F. may be uncomfortably cool, whereas in winter such a temperature is felt to be warm. Clothing alone does not explain entirely these different sensations.

A moderate amount of variability in temperature is known to be beneficial to health, comfort, and the performance of mental and physical work. On the other hand, extreme changes are not beneficial and often are definitely harmful. The high pneumonia rate prevalent among steel and foundry workers who are subjected to wide variations of temperature illustrates the deleterious effects of sudden temperature changes of wide range.

4. *Comfort*—Our sensations of comfort are dependent upon temperature, humidity, and air motion, and also the factor of radiation between a person and surrounding hot or cold surfaces.

No single comfort standard can be laid down which would meet every need, since the state of health, age, sex, clothing, activity, and degree of acquired adaptation are factors which affect comfort standards.

The greatest emphasis is always to be placed on the factor of comfort.

PUBLIC HEALTH ASPECTS

Aside from reports in engineering publications, very little information is available on the relation of air conditioning to health and disease.

In a report by Dr. Crowder on the medical aspects of air conditioning to the Association of American Railways this year, the following comments appear:

1. There appears no dependable evidence that the passing between a cooled car and the outside in either direction has an effect on the production of the common cold. These changes are regularly undergone in winter, although there is generally an increase of clothing in going from warm to cold, which in summer there is not. In summer there is also the further element of sweat.

2. There is considerable evidence that both hay fever and asthma are temporarily relieved by several hours of traveling in air conditioned trains. There seems no doubt that in hot weather cooled cars will bring a degree of relief to the victims of these conditions on the simple basis of their coolness, their lower humidity, and their relative freedom from dust, while the limitation of pollens may benefit them specifically.

3. During the terrible dust storms that obtained throughout the Central West last year,

air conditioned cars remained essentially free from perceptible dust, and passengers went through with comfort, whereas ordinary cars became at times almost intolerably dusty.

4. There is a rather common opinion that "on leaving the conditioned car the temperature change is too abrupt"; yet the same abruptness prevails in winter on entering a warmed room from without and with a much greater temperature change. It is not believed that it does any harm, though it may cause temporary discomfort. At any rate, the fault here seems to lie with the outside and not with the inside. As the lawyers would say, the weather is an Act of God, and there is no responsibility for any damage it may do. Air conditioning plans to maintain good weather inside regardless of what nature provides.

5. The criterion of our success in air conditioning is bodily comfort—no chilliness, no sensible sweating, no congestion of the skin and mucus membranes from a distorted circulation in its attempt to get rid of body heat to a reluctant environment. These are the conditions under which normal physiological functions are maintained in normal balance, so far as the medium in which we live controls them. They are, then, the conditions for the maintenance of bodily health in so far as health is affected by this same meduim.

If we accept this view, air conditioning must be a health promoting measure rather than one which holds any danger of harm. There is no evidence that it contributes to ill health if reasonably well done. With continued improvement, it may be said with confidence that air conditioning will be a benefit rather than a danger to public health.

Emancipation of Women

THE nervous strain of public competitions is in my judgment more likely to be productive of damage to the reproductive organs than any physical exertions. If such men as Perry and Crawford crack under the strain of tournament tennis it cannot be particularly beneficial to the woman's more labile nervous system. Further, stars at any game or sport either remain single or if they marry they frequently remain barren. We may therefore conclude that exercise and sport in all forms are good for women, but that there is room for doubt whether the strain of serious competitive sport and the attitude towards reproduction it imposes are beneficial either to the individual or ultimately to the nation.—Geoffrey W. Theobald, M.D., Some Effects of Emancipation on the Health of Women, *J. State Med.*, June, 1936.

Newer Aspects of Amebic Dysentery*

STUDENTS of public health will recall that in the summer of 1933 a unique outbreak of amebic dysentery occurred, with the point of origin at Chicago. The outbreak was largely synchronous with the Century of Progress Exposition. It will be recalled further that the infection in the great majority of cases was traced to sources in two hotels. The Committee on Research and Standards of the American Public Health Association appointed a sub-committee composed of engineers, health officers, and epidemiologists who studied the facts in connection with the outbreak in order to make readily available information that would be of value to sanitary engineers, health officers, and others. The report of this sub-committee, which has been approved by the Committee on Research and Standards, follows:

ADMINISTRATIVE

The committee is of the opinion that the routine examination of food handlers for the purpose of discovering carriers of amebic dysentery is impracticable, and of no value as a public health control measure.

Amebic dysentery (clinical amebiasis) should be a reportable disease in all health jurisdictions.

Neither isolation of the patient with amebic dysentery (clinical amebiasis) nor quarantine of contacts is considered necessary or desirable.

An effort should be made to determine the source of infection in each (amebic dysentery) case.

* Report of the Sub-Committee presented to the Committee on Research and Standards May 19, 1936.

Existing designs and installations of water systems in buildings should be studied by competent authorities to detect and eliminate hazards to the safety of the water supply.

The committee is of the opinion that plans for water supply piping systems in buildings, including storage tanks and accessories and the drainage system pipes, should be examined and approved by competent authorities before the issuance of construction permits, in order to prevent potential hazards to the safety of the water.

The committee is of the opinion that where a city water supply for drinking or domestic purposes is derived from a source subject to contamination, the purification process should include filtration for the removal of the cysts of the *Endameba histolytica* because of their resistance to other forms of appropriate treatment, such as chlorination.

Pending the determination of the source of infection in institutional or other localized outbreaks immediate steps should be taken to:

1. Provide a safe supply of water by boiling or changing the source of the water supply to one of known purity.
2. Utilize all known measures for the protection of the food supply.
3. Correct all obvious insanitary conditions and practices.
4. Enlist the coöperation of both a competent public health engineer and an epidemiologist.

It was voted to recommend to the Committee on Professional Education that consideration be given to the practicability of encouraging the training of a greater number of thoroughly competent protozoölogists.

ENGINEERING

(See also Engineering Appendix)

In the prevention of amebic dysentery, consideration should be given to the following engineering policies:

1. Complete physical separation of all water systems used for drinking or domestic purposes from secondary water systems.
2. Regular systematic and thorough inspection for cross-connection hazards on premises wherever secondary water systems exist or where the domestic water supply is re-used for any purpose.
3. Establishment of practical working policy for supervision and control of such hazards between municipal water works and the health authorities.
4. Education of architects, designing engineers, building owners and operators, and plumbers in the prevention and correction of such hazardous conditions.
5. Protection of the water supply for drinking or domestic purposes against contamination through fixtures, processing tanks, sewers, etc.
6. Adequate enforcing of an up-to-date plumbing code governing installation of water supplies, fixtures, and drainage systems.

EPIDEMIOLOGICAL

In the epidemiological study of amebic dysentery, in addition to such previously accepted factors of transmission as by eating of contaminated food, by hand contact with moist objects soiled with discharges of infected individuals, and by flies, consideration should be given to the following facts:

1. Transmission by water has been established beyond question.
2. A water supply indicated as satisfactory by the physical, chemical, bacterial, and microscopic analysis made in accordance with standard methods of water analysis may not be free from living pathogenic protozoa.
3. Manifest clinical disease occurs in but a small proportion of those newly infected.
4. Evidence as to the distribution of the infection may be effectively sought through the examination of stools of healthy persons possibly exposed.
5. Amebic dysentery should be looked for in the epidemic occurrence of any water-borne disease.

CLINICAL

Delay and inaccuracies in the diagnosis, and inadequate or inappropriate treatment contribute to the severity of amebic dysentery and may be responsible for a high mortality rate. Better clinical teaching relative to this disease is emphasized as an effective measure for control and treatment. It should be emphasized to all physicians and medical students that:

1. Amebic dysentery is not limited to the tropics.
2. Atypical clinical manifestations are commonly encountered. Acute surgical conditions of the abdomen may be closely simulated.
3. Specifics are available which if administered early and in adequate dosage almost invariably bring prompt relief and rapid recovery.
4. Diagnosis of amebic dysentery should be considered in any case characterized by blood and mucus in the stools.
5. Entire dependence should not be placed in negative findings of stool examination in diagnosing clinical amebic dysentery as the disease may exist even though laboratory findings are negative.

NOMENCLATURE

It *is* the opinion of the committee that if the term "amebiasis" be used it should be followed by the words *amebic dysentery* in parentheses when a clinical condition is referred to and by the word *carrier* in parentheses when a carrier is meant.

Those interested in a more detailed discussion of the various aspects of amebic dysentery are referred to *Bulletin 166* of the National Institute of Health, entitled "Epidemic Amebic Dysentery—The Chicago Outbreak of 1933."

ENGINEERING APPENDIX

Recognizing that something more than a simple delineation of engineering policies pertaining to safeguarding water systems is desirable, the following supplement to this report is submitted.

I. SEPARATION OF DRINKING OR DOMESTIC WATER SUPPLIES FROM SECONDARY SUPPLIES

Definition: By a secondary water supply is meant water from a source other than that used for the drinking or domestic supply in the community, institution, or premises, including reused water from any source.

A. Where a secondary water system exists on any premises, it is generally deemed prudent and in the interest of public health to require that the public water system be definitely protected against any possibility of pollution from the secondary system. An effective way of accomplishing this is to require that the premises be supplied from the public system through an intermediate reservoir or tank with piping and fittings so arranged that under no circumstances could the secondary water be forced or drawn back into the mains of the public system. The tank should be so located and covered as to be protected against flooding by sewage. Preferably it should be above ground. Such a requirement may, in some instances, necessitate re-pumping of the water obtained from the public system. This extra cost is not considered unreasonable in view of the potential risk to the public water system which may exist because of the maintenance of the secondary source of supply. An example of this case would be a plant or premises maintaining a secondary water system from a polluted source for fire protection or industrial uses.

B. Although in new installations complete separation of water systems may be accomplished, there is no assurance that at some future date cross-connections between the domestic and secondary system will not be made. Therefore, practical and effective means must be adopted to check and minimize this possibility. One to be recommended is the identification of the various exposed piping systems by painting them distinctive colors. Light blue is suggested for the domestic water system. Other checks are the keeping of up-to-date accurate *piping diagrams* and the centralization of authority for all piping changes or additions. The lack of proper piping diagrams may result in cross-connections being made innocently by parties not familiar with local piping installations or because of lack of proper working drawings. This is especially true when work is done by outside contractors or where a new operating staff is assigned to a plant. By centralizing responsibility and authority for all piping changes in one competent person, much could be accomplished in preventing cross-connections of "convenience" and "ignorance" which are made more frequently than is generally recognized. Before changes or additions to the water piping systems on premises are made, the plans should be approved in writing by the proper official in charge of plumbing inspection, or of the public water supply, or both.

C. Under certain unusual and very extreme conditions, where the hazard to life because of fire is obviously and demonstrably greater than the health hazards, if a physical connection be provisionally permitted between a domestic and a secondary water system, the interconnection should be protected by approved double check valves with a drain in the pipe between the two checks valves and an alarm system to

warn the responsible operators when water passes by either check valve. Such a system should be under regular and frequent inspection of the health and water authorities and should be fitted with the necessary accessories to permit convenient testing of the double check valve system. An interconnection of this type should be made only after securing written approval of the responsible health authorities, and should be removed as soon as some other safe and adequate means of fire protection can be obtained.

II. INSPECTIONS TO DETECT CROSS-CONNECTIONS AND ALLIED HAZARDS IN WATER AND DRAINAGE SYSTEMS

Every health and water department should catalogue premises within its jurisdiction where secondary water systems are maintained. Regular and frequent inspections should be made to see that cross-connections are not made and that all other potential hazards are eliminated or effectively guarded against. These inspections should be thorough in every detail. Inspectors should be instructed to analyze plant conditions from the standpoint of potential hazards which might develop under abnormal as well as normal conditions. Usually pollution of water supplies results from extraordinary conditions neither expected nor provided for.

Practical tests should be made of hydraulic conditions established in the piping and drainage systems when subjected to abnormal flow conditions. The use of apparatus and instruments for recording performance during these tests is recommended. In general, tests should subject the entire waste system to pressure sufficient to detect leakage which might not develop under average flow conditions. The water system should also be subjected to negative head or vacuum to detect possible siphonage from fixtures, processing tanks, or drains.

In old buildings, the pipes should be inspected for corrosion and deterioration of any character, especially in the upper half of the pipes. Piping, tanks, or other equipment subject to strain under abnormal conditions should be carefully examined. Examples of abnormal load conditions are: water hammer, pressure due to heat or ice formation, failure of safety valves or vacuum breakers, excessive wind and snow loads, flooding, failure of tank supports.

Under no circumstances should sewer or drain pipes pass directly over open water tanks or premises where ice or food is being stored or handled.

Food and water, including ice, should not be stored, prepared, or handled where there is any possibility of flooding due to back flow of sewers under pressure. Drains from water tanks, filters, refrigerators, and other food storage space should not be directly connected to sewers.

III. WORKING POLICY BETWEEN HEALTH AND WATER WORKS OFFICIALS RELATIVE TO WATER SUPPLY HAZARDS AND RESPONSIBILITIES

A. It is particularly important that public health and water works officials coöperate with each other closely, in the elimination and prevention of cross-connections, and also with fire and building department officials in general.

B. Definite policies should be agreed upon, defining the respective jurisdictions and permissible remedial measures which may be applied for correction of defects discovered, and approved preventive measures to guard against creation of new ones.

C. Public health engineers should be employed by health departments to supervise the technical work under their jurisdiction in this field, and promote harmonious coöperation with the engineers in the water department in their portion of the work. Wherever

a health department is unable to secure the services of an engineer, because of small size or other reasons, some arrangement should be made for the assignment of an engineer by the water department to coöperate with the local and state health departments, keeping them adequately informed, and being guided by them in general matters of policy.

IV. EDUCATION OF ARCHITECTS, DESIGNING ENGINEERS, BUILDING OWNERS AND OPERATORS, AND PLUMBERS IN THE PREVENTION AND CORRECTION OF SUCH HAZARDOUS CONDITIONS

A. The education of responsible parties in the reasons for and methods of preventing and eliminating cross-connections and similar hazards is of paramount importance.

B. The method will depend upon local conditions, and might embrace:

Courses in medical, engineering, and architectural schools
Direct contact with plumbers and architects
Coöperation with building owners' associations and technical, trade, or professional societies, especially in the design, construction, and operating groups
Magazine and newspaper articles, radio, and motion pictures
Demonstrations by use of typical installations of dangerous connections and equipment
Conferences with those who installed or permitted the continued use of hazardous connections
Conferences with manufacturers of equipment embodying objectionable features
Suggestions offered to contractors or others seeking approval of plans

V. PROTECTION OF WATER SUPPLY FOR DRINKING AND DOMESTIC PURPOSES AGAINST CONTAMINATION THROUGH FIXTURES, PROCESSING TANKS, SEWERS, ETC.

Wherever water enters a fixture, tank, or container through a pipe terminating below the surface of its contents, there exists a possibility that such contents may drain or be siphoned into the water supply pipes. In such cases, the fixture may act as a supply reservoir or stand-pipe during periods of reduced pressure. Should the fixture or container hold pathogenic bacteria, as in bottom supplied instrument sterilizers in hospitals, or chemical poisons, as in many tanks and vats in factories, such submerged inlets present real hazards to the safety of the water supply. Reduction in pressure and conditions of negative head (vacuum) are not at all uncommon in water systems of hilly communities and in buildings, particularly on upper floors. They may be caused by many conditions, such as (a) shutting off the water pressure for repairs, (b) heavy draughts of water on lower floors, (c) breaking of pipes, (d) aspirator or sucking action of rapid flow in main pipes past branch connections, (e) use of fire engines in neighborhood, (f) cutting off water pressure to reduce flooding during stoppages in sewer pipes.

The existence of overflow connections, such as commonly found in bath tubs and lavatories, is insufficient protection because often the fixture contents may rise high enough to submerge the inlet in spite of such overflow connections, or stoppage of the drain pipe may permit sewage from higher levels to back up into the fixture through the overflow.

Wave action in containers may cause intermittent submerging of the inlet. Owing to the possibility that water may be drawn up in a miniature water spout if the inlet be near the surface, though not actually submerged, the inlet should be well above the highest level to which the fixture contents may possibly rise.

Circulating contents of fixtures or tanks as in air washers, swimming pools, etc., may also present hazards through priming connections to circulating pumps, particularly if the tanks are directly connected to the sewer. In

general, all such fixtures and containers which are connected to sewer systems or may contain water bacterially or chemically contaminated, should be regarded as part of the sewer systems and no direct connection of the water pipes to them should be permitted. If, for any reason, such direct connections are permitted, as in the case of flush valves, adequate protection against back siphonage should be required.

VI. ADEQUATE ENFORCEMENT OF AN UP-TO-DATE PLUMBING CODE GOVERNING INSTALLATION OF WATER SUPPLIES, FIXTURES, AND DRAINAGE SYSTEMS

A. Even in progressive and well managed cities, too frequently the plumbing codes are antiquated and obsolete, giving but relatively little attention to health protection and to prevention of water contamination, in proportion to the importance of these matters.

B. Much new information has come to light since the older of such codes were promulgated, which should now be utilized in modernizing them and increasing the stringency of sections pertaining to the protection of health. In amending old codes or drafting new ones, attention should be given to the following considerations:

1. The failure of customary amounts of residual chlorine in drinking water distribution systems to protect against spread, through water, of amebic dysentery and possible other diseases.
2. The increasing number and variety of uses for water in industry.
3. The new types of fixtures developed for processing, storage, washing, hydraulic, and refrigerating equipment in which water is used, such as air conditioners, heat exchangers, condensers, presses, etc.
4. The trend toward higher buildings, involving greater differences in pressures and greater possibilities of creating conditions of negative head or vacuum in water pipes.
5. The premium on space above ground for tanks in buildings located in centers of cities where property values are high.
6. The increasing requirements for fire protection as congestion in urban population becomes greater.
7. The greater demands for water for special purposes, especially air-conditioning, which may make past standards for pipe sizes entirely inadequate, and may promote loss of pressure and consequently make more frequent the contamination of water through submerged inlets, particularly where the topography is hilly and buildings are high.
8. The development of new types of vacuum breakers and siphon preventers.
9. The growing inadequacy of old sewers as adjacent property is improved, causing backing up and flooding by sewage into basements.
10. The tendency to place more and more service and operating equipment below the level of the street sewer, in sub-basements of buildings in areas of high land values, thus increasing hazards of direct sewer connections of water equipment in such deep excavations.
11. The increasing use of fixtures with overflows, condensate drains, or steam vents which may be connected with sewer or waste pipes, permitting sewage contamination of fixture contents, such as soup kettles, utensil sterilizers, autoclaves, sterilized water tanks, etc.
12. The re-use of water previously used, stored, or handled in a manner which might permit it to become contaminated, in order to conserve water where increasing demands are taxing to the utmost the capacity of the plant to supply enough water during peak periods.
13. Electrolysis causing leakage in sewer pipes due to grounding of electric wires from radio sets and other electrical apparatus.

C. Administration of the plumbing code should be vested in officials having the public health viewpoint and sufficient knowledge of the health hazards involved to give adequate attention to its many highly technical health problems. The plumbing code should be enforced by the health department, through the administration and under the direct charge of a competent public health engineer, in order to assure that the public health aspects of plumbing will be given the kind of attention warranted by their importance.

Plumbing inspectors should be given training in the elements of public health as related to water supplies, in order

that they may approach their tasks in the proper way. The reasons for the requirements of the code should be explained to plumbers and to the public in order to secure the coöperation of all concerned in observing the provisions. Restriction of plumbing work to competent persons by some form of registration, certification, or licensing is essential.

D. Plumbing plans should be submitted to and approved by the proper municipal official before the building permit is issued in all new installations and before the work is done on all subsequent alterations of importance.

Emancipation of Women

I HAVE made provocative and sweeping statements, but I would not like to convey the opinion that I despair of the modern girl. I find her honest, frank, a true "sportsman," knowing how to win and how to lose, who has shed hypocrisy more completely than the corset. The revolt of youth against incompetent old age which has the stranglehold on all civilized activities is understandable and commendable. Youth must, however, remember that the environment, including all the advantages, in which they live is the result of the labours of a long line of noble men and women and must not confuse the obstructionist tactics of the old men, possessing all the power in their hands, with eternal values. In the beginning God made them male and female and these differences are biological not man made. The stability of the race must depend on the purity of the family, and this cannot be maintained by forgetting biological facts. Sex must neither be flaunted nor forgotten and the married woman who claims to have the sole right over her own body is a biological reject. Of all the effects of emancipation the mental restlessness is the most ominous, while the need for physical culture and instruction on diet and hygiene are pressing. In my judgment a reorientation of values is much to be desired, and more stress should be laid on those which are spiritual.—Geoffrey W. Theobald, M.D., Some Effects of Emancipation on the Health of Women, *J. State Med.*, XLIV, 6 (June), 1936.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

SYLVATIC PLAGUE

WE have published in another column the Report of the Sylvatic Plague Committee. The use of the term *sylvatic* seems to us to be open to criticism. In the report of the committee we are correctly told that Dr. Jorge proposed the term *peste selvatique*, which would be "selvatic plague" in English. It is notable, however, that in his paper presented to the Comité de l'Office International d'Hygiene publique, the spelling *selvatique* as well as the spelling *silvatique* is used. The headings of the paragraphs are invariably spelt *selvatique,* and it does not seem that the spelling *silvatique* is accidental or a typographical error. Jorge calls attention to the fact that there is a type of plague which rages among wild animals occupying desert-like territory. The term *selvatic* has been accepted by Stallybrass and also by Wu Lien-Teh, who in his latest volume, *Plague* (1936), discusses the use of the word at some length. He says ". . . selvatic plague is dangerous to man only when he invades the remote endemic areas populated by wild rodents." The committee calls attention to the review[1] of the Memorial Volume, 1912–1932, edited by Wu Lien-Teh, in which the term *sylvatic* is used. They state that there is no doubt that the English word *sylvatic* is the correct spelling of the word which Jorge spelled *selvatic.*

We have studied a number of dictionaries, but will confine ourselves entirely to Webster, which for years has been the standard for our *Journal;* to the Standard; and to the Oxford, which is the last word in dictionary making for the English language. We find *selva* meaning the rain forest of the Amazon. According to the Oxford, this is also erroneously spelt *silva,* and usually used in the plural. It is derived from the Latin word *silva,* a wood, forest, woodland, "commonly misspelt *sylva*" in imitation of the synonymous Greek word *hyle.* All dictionaries seem to be at one on this point. Under the word *silva* we are referred to *selva.* Under *sylvan,* one meaning is an animal, especially a bird, living in or frequenting woods. The word itself is also used as an adjective:

"belonging, pertaining, or relating to, situated or performed in, associated with, or characteristic of, a wood or woods." It may be noted here that *silvan,* also spelt *sylvan,* is the more commonly used adjectival form. Webster says *silvan* represents etymology more exactly, but *sylvan* is in more general use. We find in the Oxford the word *sylvatic, silvatic,* L. *silvaticus,* marked "rare" (dating back to 1661), "belonging to or found in woods, transf. rustic or boorish." Webster also gives *sylvatic,* derived from the Latin word *sylvaticus,* "better spelt *silvaticus,*" meaning sylvan, also rude or uncivilized, Now Rare.

Without going further into the derivation, proper spelling and proper use of the word, we wonder whether the introduction of a new term is wise, and especially one over which there is room for criticism. We have seen that the best authorities dislike the spelling *sylvatic.* It is not the term proposed by Jorge, apparently the originator of the entire idea. It is not the spelling accepted by authorities on plague, by Stallybrass, or by Wu Lien-Teh, who incidentally is an exceptionally good linguist. We do not know who wrote the review in the *J.A.M.A.* referred to, but there is no discussion of the spelling *sylvatic,* and no evidence as to whether or not the reviewer made a study of it.

The term, whatever its correct spelling, has been applied to a type of bubonic plague found among wild rodents, and is used to differentiate the disease as found in them and as transmitted to man, from the ordinary, well known type of bubonic plague carried by "domestic" rodents, among which the rat stands preëminent. Is it not unfortunate to introduce a word which we have not been able to find in any medical dictionary nor in any English dictionary as applied to plague? As mentioned by the committee, the term has not met with unanimous approval among health officers. The report states that this type of plague is zoölogically and geographically different from the plague of the Middle Ages, but just the same it seems to be bubonic plague, whether or not it differs in some respects from the classic disease. Would it not be better simply to call it wild rodent plague, which is in accordance with the description given by Jorge and the actual words which he uses?

OCCUPATIONAL DISEASE CONTROL

DUST has often been thrown in the public eye to becloud an important issue, but in the case of silicosis, dust has caught the public eye and directed it to an important public health problem, that of occupational disease control. Thanks to the newspapers and other publicity agencies, many people who heretofore thought of public health problems as concerned only with placarding for communicable diseases and quarantine, now realize that there is hardly any hour of the day or night when their personal health is not being assured by the efforts of public health workers whose work embraces the whole field of preventive medicine entailing close coöperation with the general practitioner and all agencies concerned.

The view of the public health worker engaged in occupational disease control extends beyond diseases caused by dust, now occupying the foreground of the picture, and includes the entire panorama of the occupational disease landscape.

Fifteen million persons are gainfully employed in manufacturing and mechanical industries and extraction of minerals in the United States. This large group, which is of tremendous importance to the welfare of the nation, spend nearly a third of their adult lives in occupations of which more than 900 are potentially hazardous to health. Numerous investigations of the U. S. Public Health Service, other health agencies, and individual organizations and workers, both here and abroad, have established that morbidity and mortality rates are definitely higher for the general industrial population, and that certain occupations are of first importance as factors in the causation of excessive sickness and mortality rates. These excessive rates not only affect the industrial population but increase the rates of morbidity and mortality of the general population. The life expectancy of industrial workers is several years less than for those otherwise employed. Age for age the mortality rate for the industrial worker has been shown to be from one and one-half times to more than double the rates of the non-industrial worker. Tuberculosis rates are much higher in the industrial group and add to the cases in the general population; pneumonia rates are more than twice as high, and degenerative diseases show rates two or three times as high in the industrial group. It is concluded that while hereditary and innate differences play some part, the most important factors are the conditions incident to industrial employment such as toxic gases, dusts, specific occupational poisons, extreme temperature variations, and numerous other industrial health hazards.

The control of health hazards in working environment constitutes a public health problem of the first magnitude. Most of these hazards consist of exposure to materials injurious to health, and though numerically a larger proportion of these workers are exposed to materials, other than dusts, which affect their health, excessive exposure to quartz dust, with its resultant silicosis, is today recognized as the most serious of the occupational diseases.

Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service,[1] brings out clearly the duty of public health officials in regard to their responsibility toward this problem and says we must "focus our attack toward the goal of eradication (of tuberculosis) upon, first, the young woman in industry or young mother; next, upon the worker in the dusty trades which form the background for many an unpublicized 'Gauley Bridge' disaster. . . ."

Public health officials have long recognized the importance of occupational disease control as one of the fundamental factors underlying any public health program. Of what use will our prenatal, child hygiene, or communicable disease control programs be if we do not continue to safeguard the worker's health in his environment.

Aside from effects on health, the economic implications are tremendous, for these conditions affect the earning capacity of the adults who are frequently the support of the family. Industry is burdened with tremendous costs for compensation; claims for silicosis alone are written in millions.

Occupational disease can be prevented. Industry cannot do it itself and no agency other than the public health authorities is organized or constituted to undertake it.

The State and Provincial Health Authorities of North America adopted a resolution stating that occupational disease prevention should be an integral part of the public health program. The American Public Health Association passed a similar resolution,[2] the Presidential Address containing specific recommendations for the inclusion of an occupational disease control program in public

health activities,[3] and recently the American Medical Association passed a resolution to the same effect. During the last few years articles by health authorities have appeared in various technical journals stressing the necessity and importance of this work, and that it is being undertaken by departments of health as part of their public health program.

It is essential that all of the public health phases of the problem be kept together just as in other public health measures, such as the epidemiology, survey and study of the working environment, and the necessary regulatory and enforcement measures.

The provision of funds for occupational disease control through Section VI of the Social Security Act created an immediate demand from health officers for appropriations to inaugurate and enlarge their occupational disease program, and permitted a concerted attack along the entire front of the occupational disease line by departments of health in 19 states and large municipalities.

Many of these states have taken advantage of money provided by federal funds for training purposes, and have sent their personnel to receive special training in problems of occupational disease control in a course given by the U. S. Public Health Service at Washington. These men received an intensive course of lectures and demonstrations, field and laboratory work, and will return to their respective health departments more capable of attacking the particular problems of occupational disease control in their own states. It is planned to continue these intensive courses, and to augment them in particular cases with special training at some of the universities where courses in the various phases of occupational disease control will be given.

We may now expect, in the not too distant future, to see the trend of silicosis and other occupational diseases approach the minimum residual as in typhoid and diphtheria.

EDWIN OAKES JORDAN

IT is with the sincerest sorrow that we record the death of Edwin Oakes Jordan on September 3, 1936. Of rugged New England stock, he was educated at the Massachusetts Institute of Technology and was one of the earliest and most distinguished of Sedgwick's pupils.

After obtaining his Ph.D. at Clark University, he went to the new University of Chicago with the group from Clark that had faith in Harper and his educational ideas. All of Jordan's academic career was passed at Chicago. Here he built a department of bacteriology in which graduate instruction was emphasized. The roster of men and women teaching in universities and colleges and engaged in public health laboratory work, trained wholly or in part under him, is impressive. He was given the honorary degree of Doctor of Science by the University of Cincinnati in 1920.

Jordan's scientific work began immediately after his graduation from the Massachusetts Institute of Technology in 1888. He was in the group working under Sedgwick and Drown in the Massachusetts State Board of Health. Those were the days when bacteriologic technic was in its infancy and gelatin

plates were literally "plates" but Jordan's first publications in the almost forgotten *Technology Quarterly* for 1889 and 1890 show evidence of the same careful work that characterized the articles of later years. His interest in sanitary bacteriology aroused at this time was maintained throughout his nearly 50 years of active work. During the Chicago Drainage Canal suit, Jordan and his associates accumulated an immense amount of valuable data on stream pollution and the factors influencing the growth or disappearance of bacteria in streams. His classification of water bacteria made at that time, stands today. His scientific papers cover many fields of bacteriology. These range through early work on bacterial enzymes, milk and food bacteriology—particularly that phase dealing with food poisoning; a series of papers dealing with the bacteriology of influenza prepared under his direction and including his own contributions dealing mainly with the epidemiology of the disease and with the "influenza" group of bacteria; an extensive study of the paratyphoid group of organisms based on an unparalleled collection of cultures from all parts of the world. These studies on the paratyphoid group are representative of all of Jordan's scientific work. He was meticulous in his laboratory technic. Constant repetition, frequent and careful observation, untiring patience in solving laboratory problems, were the characteristics which produced data of indisputable accuracy. His scientific papers written in clear, concise, and faultless English can well serve as models for the rising generation.

In addition to laboratory investigations, the field of epidemiology was always an attractive one for him. His report on typhoid fever in Winnipeg is a classic and was the precursor of many signed and unsigned reports of epidemics, particularly of typhoid fever. Here again, his analytical mind and unwillingness to draw conclusions except from sufficient data are as prominent as in his scientific studies. As an epidemiologist he was in the front rank.

While not a fluent extemporaneous speaker, Professor Jordan's addresses and classroom lectures were clear and logical and were always carefully prepared and as carefully presented. No student could leave one of his lectures without a clear picture of the subject under discussion. Jordan contributed to bacteriological education through a readable and useful textbook on bacteriology designed particularly for students. First published in 1908, this has passed through eleven editions under his skillful supervision.

In addition to his work as teacher and investigator, Dr. Jordan found time to act in a variety of advisory capacities. He served for a number of years as a member of the International Health Board of the Rockefeller Foundation and, later, on the scientific advisory board when the International Health Division of the Foundation was formed. He was a member of the board which recommended drinking water standards to the U. S. Public Health Service. During the World War he was in charge of one of the laboratory cars of the American Red Cross and studied meningitis in several army camps. Much space would be required to list other activities of this sort.

Since joining the Association in 1899, Jordan has been truly an active member, his main interests naturally centering about the Laboratory Section. He was a member of the group which formed this section and served it as well as the Association in various capacities. When the Epidemiology Section was formed in 1929 he was one of its earliest members. He served on the Executive Board 1924–1925, on the Governing Council 1925–1930, and was Treasurer of the Association 1928–1929. In 1934 he received the Sedgwick Memorial Medal.

He was also concerned with the formation of the Society of American Bacteriologists and of the Epidemiological Society. As a co-founder and co-editor of the *Journal of Infectious Diseases* and as editor of the *Journal of Preventive Medicine* he had opportunity not only to publish some of the best scientific contributions but also to advise and encourage younger contributors.

Modest and retiring almost to a fault, he can well serve as an example of one who has attained eminence in his profession without the aid of the self advertising regarded by too many as necessary for reaching scientific prominence. As a companion he was a delight because of his wide reading, marvelously accurate memory, and his acquaintance with scientific men throughout the world. He will be missed by his contemporaries, his former colleagues, and the host of students who have received training and inspiration from him.

AN UNPAYABLE DEBT

THERE are few things more interesting than going over the old lists of members of a scientific association. They correspond closely with the papers found in old volumes of transactions—always a source of interest and often of information. Too often we forget what the older members of an association have done, and often the younger members are likely to regard the old ones as back numbers.

We owe an everlasting debt of gratitude to our old members for what they did to determine the character of our Association and for building a firm foundation on which it has stood now for nearly 70 years.

Therefore the movement to recognize a group of the older members is particularly gratifying. The Committee on Fellowship and Membership has been given authority by the Executive Board to give some special recognition to those who have been affiliated with our Association for 40 years or more. This will take the form of a certificate which will be presented by the President of the Association as a feature of the banquet at our coming meeting in New Orleans.

There are only eight such members. We would that there were more, but this desire does not lessen in any degree the honor we pay to those who are still with us.

It is almost impossible not to recall the past on an occasion of this sort. One of our number, Dr. J. H. Kellogg, became a member when Elisha Harris, a man much respected by all, was President. Another, honored all over the world and who is justly regarded as the foremost city health officer of all, is Dr. Charles V. Chapin, of Providence. He joined under the presidency of Henry P. Walcott, a noted hygienist of Massachusetts. Daniel W. Mead, the well known professor at Wisconsin, joined under Samuel H. Durgin. Jesus E. Monjaras became a member under that grand French Canadian, Frederick Montizambert. Miss Marion Talbot became a member under another delightful French Canadian, Emmanuel P. Lachapelle, of Montreal. George A. Soper became a member under William Bailey, of Kentucky, while Robert S. Weston, and William C. Woodward joined under the presidency of that noted Mexican hygienist, Eduardo Liceaga.

What memories these names bring to all who are interested in our Association and its history! Along with that group comes Henry B. Horlbeck, President of our Association on its 25th anniversary, who in season and out of season

urged the study of yellow fever. One cannot but regret that he could not live to see the triumphs which have been achieved in regard to this disease. Close along with him was Henry D. Holton who, unknown to the majority of members, frequently gave out of his private purse to help the Association. A little later came Walter Wyman, for many years the distinguished Surgeon General of the Public Health Service, and just next, Carlos J. Finlay, of Cuba, who showed his wonderful powers of observation in selecting the mosquito which has been shown to be the carrier of yellow fever, and who furnished the eggs from which the mosquitoes used by Walter Reed and his associates were reared. If we have members who do not know the history of our Association, let them read.

The length of time which these eight have been members of our Association is an inspiration. There is no question that they have found the Association useful to them and worthy of their allegiance. All have gained the highest distinction in their respective professions. They have reaped success as well as honor. What they have gained from our Association through their years of experience is open to every member. Will not their example be an inspiration to those who are now with us or who may join our ranks later?

Every member of our Association joins with our officials in doing them honor and wishing for them health, long life and additional honors.

ERADICATION OF BOVINE TUBERCULOSIS

WE have repeatedly called attention to the good work of the Bureau of Animal Industry, U. S. Department of Agriculture, in the eradication of bovine tuberculosis. This department of our government has been unceasingly active and very efficient under the direction of the Chief of the Bureau, Dr. John R. Mohler.

A recent announcement states that Nebraska is the 40th state of the Union to be certified as a modified accredited area. That a disease which has been such an economic scourge and menace to human health has been brought under control to so great an extent is a matter for congratulation not only to the department which has been responsible for the work, but to the cattle raisers and the consumers of milk. The success which has attended efforts in this direction speaks well for the soundness of the ideas upon which the campaign for eradication has been based as well as for the energy with which it has been carried out.

PUBLIC HEALTH EDUCATION*

The Last Call—See in the September issue of the *Journal* announcements of Public Health Education Headquarters at New Orleans.

If you act quickly you may yet have a share in that service to other health agencies.

Send! Come! Bring!—*Send* for Public Health Education Headquarters at New Orleans, as explained in the September issue.

Come to New Orleans if you have any part in doing health education, or in handling health education materials.

Bring with you questions you want answered; good ideas gleaned from your year's work; copies of your printed or mimeographed educational material or plans of work to be placed on the " Free " or " Give-away-table "; and a pocket display in two parts: (a) a concise but complete outline of what you have been doing; and (b) a sample set of the material you used.

Motion Pictures at New Orleans —Last year motion pictures were scheduled for display at Health Education and Publicity Headquarters. This turned out to be quite unsatisfactory.

So at New Orleans the *movies will be put on at the close of regular sessions of the Public Health Education Section.*

If you have a 16 mm. picture to be shown please quickly inform Evart G. Routzahn, 130 E. 22d St., New York, N. Y.

Do not send film to New York. Ship to Dr. C. C. Dauer as noted elsewhere under " Shipments to New Orleans." Or, deliver to Mr. Routzahn at Health Education and Publicity Headquarters.

It is hoped that every exhibitor will supply a mimeographed sheet giving a synopsis of his picture and information as to its production, cost, use, etc.

Shipments to New Orleans—Packages for Health Education and Publicity Headquarters should arrive in New Orleans by Friday, Oct. 16; should be prepaid; should be addressed as follows:

For Health Education and
Publicity Headquarters
Dr. C. C. Dauer
Tulane University
1430 Tulane Ave.
New Orleans, La.

Deliveries may be made in person at the opening of the convention if you send word to that effect. Otherwise late deliveries would disrupt the arrangement of displays.

A Sheet of Information—A mimeographed sheet of information is desired with every display at Health Education and Publicity Headquarters, and with every movie shown at close of Public Health Education Section meetings. This sheet would add much to the interest and value of any display.

Please describe the display, and

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

answer all the questions you think anyone might wish to ask about what you are showing.

Return Packing and Shipping—If you wish your exhibit returned, and if you will not be represented at New Orleans, please be very sure to arrange for re-packing and shipping. This can be done for you at small expense.

Specific information as to the disposal of your display is requested.

Three Important Events—At this time we may no more than bulletin three events of much significance to public health education.

A *Transparent Woman,* mate to the Transparent Man, produced by the German Hygiene Museum, has been brought to this country by S. H. Camp, manufacturer of Jackson, Mich. The first and only female transparent model is now being shown at the New York Museum of Science and Industry preceding a wide tour of the country.

Dr. Otto Neurath, known widely for his development of pictorial symbols for the presentation of statistics, is to be in this country for a period of several months. Dr. Neurath will attend the New Orleans convention.

The New York Exposition, announced for 1939, has at least encouraged the idea of having an adequate public health display.

Additional information about the plans will soon be available.

Publicity for Public Health Nursing—The August, 1936, issue of *Public Health Nursing* (50 W. 50th St., New York, N. Y. *35 cents*) includes a group of articles on publicity, interpretation, or education, whichever you choose to call it.

Anne M. Goodrich, Henry Street Nursing Service, tells about "Making a Movie for a Visiting Nurse Service." The experience reported offers working suggestions for other cities and other kinds of health work. Miss Goodrich thus emphasizes the value of the motion picture:

> As I have been giving publicity talks explaining the visiting nurse service this year, both without showing the film and in conjunction with its presentation, I have been very forcibly impressed with certain facts. When the talks to groups (ranging from one-half to one hour in length) have been made without the showing of the film, the questions asked by members of the audience have shown that they did not have a clear understanding of points which I had stressed. It was especially difficult to make them realize that nurses not only go into the poorer homes where the patients cannot afford to pay, but also go into the better type of homes where the patients pay for the service, either in full or in part. On the other hand, when the picture has been shown there have usually been even more questions from the floor, but these have related to points brought out in the talk and have shown almost without exception that there was a clear grasp of the objectives of the nursing service—this even though the time allotted to the entire program was only half an hour and all but ten minutes of this time was taken up by the showing of the picture. . . .

Elma Rood, associate in charge of health education, T.V.A., in "Community Health Education in Communicable Disease Control," an article to be read as a whole, suggests "steps for achieving real community planning for a health department program for the control of communicable disease."

"What Is Wrong with This?" quotes a local nursing service news report of a meeting of its supporters. On another page are listed 13 ways in which the news story is "wrong."

The issue includes "Publicity for Your Nursing Service," by David Resnick; "The Movie Problem," by E. S. Cornell; points on poster making; the use of radio (which will help advertisers much more than nursing organizations); home-made silhouette making by photography; and other articles.

Fire! Fire!! Fire!!! — Deaths through fire are akin to deaths through accidents in their interest to health agencies.

Moreover, health agencies as fallible human institutions need the stimulus of community effort to make sure that they provide maximum fire prevention for their own employees.

Hence we should have given early notice of "Fire Prevention Week," Oct. 4–10, 1936. It is not too late to do something. Write to National Board of Fire Underwriters, Public Relations Department, 85 John St., New York, N. Y. Ask for price list and samples of fire prevention material, and copy of *Safeguarding America Against Fire*.

Health Speech Contest—It has been done now and then, but we have long wondered why more is not done toward getting young people to voice health ideas and information.

Now that lively tuberculosis executive, Irma Collmer, St. Joseph County Anti-Tuberculosis League, South Bend, Ind., has gone and done it, and then told all about it.

A Christmas seal speaking contest was put on with the coöperation of the public speaking departments in the senior high schools of the county.

One of the first assignments given each student enrolling in speech classes for the fall term is a 5 minute talk on the Christmas Seal and its relation to the work of the St. Joseph County Anti-Tuberculosis League. The League supplies to each of these students an abundance of reference material, such as pamphlets on the nature and treatment of tuberculosis, and material dealing with the importance of early diagnosis and the history of the Christmas Seal. Reports of national, state, and local activities are also provided so the students have a good background of knowledge from which to select the subject they wish particularly to stress. They are also encouraged to visit the League office and to follow any leads they have relative to human interest stories.

The first week in November a committee composed of high school faculty members listen to all the talks and select the best 10 for the finals. Before the finals these 10 students are given an opportunity to polish up their talks and to gain experience in presenting them by appearing before the different sponsor rooms in the school. Thus, everyone in the high school will hear at least one of these talks and thereby become Christmas Seal conscious.

The finals are scheduled for the middle of November. The League appoints 5 judges to select the 3 prize winners. These judges are always representative and well known citizens such as the superintendent of schools, a minister, the president of the Tuberculosis League, one of the county judges, the mayor, and some representative from the P.T.A.

The prize winner gives his talk over the local brodacasting station in addition to receiving a cash award of $1. The second prize is a cash award of $.75 and an opportunity to speak before one of the local luncheon clubs such as Rotary or Kiwanis. The third prize winner receives $.50 and an engagement before some church group.

The following basis for scoring is used by the judges:

1. Material (20)
   - Knowledge
   - Judgment
   - Organization
   - Interest
2. Language (20)
   - Choice of words
   - Grammar
   - Sentence Structure
   - Pronunciation
3. Voice (20)
   - Quality
   - Inflection
   - Distinctiveness
   - Rate
   - Force
4. Communication (20)
   - Directness
   - Conversational
   - Response to audience
   - Confidence
5. General Impression (20)
   - Ease
   - Posture

The purposes of the contest are:

1. They give the students a fundamental knowledge of tuberculosis and indirectly educate the teachers and parents who are for the most part interested in the talks the children are preparing to give.

2. They afford an opportunity for newspaper publicity—announcements of the contest, the names of the participants, the names of the judges and the prize winners are all good newspaper copy. Pictures of the 3 prize winners from each high school are always run. The prize talk is usually published in the monthly school magazine and is also given before the general assembly of the high school.

3. They create a speakers' bureau. Students who participate in the finals serve as members of a speakers' committee subject to call before such groups as Parent Teacher's Associations, luncheon groups, missionary societies, and other clubs invited to ask for Christmas Seal speakers.
4. They make a close tie-up between the Tuberculosis Association and the schools.

Last year's prize speech is given in full.

In *Bulletin*, National Tuberculosis Association, 50 W. 50th St., New York, N. Y. Sept., 1936.

Libraries and Social Hygiene—A "Fourth Annual Library Number" of *Journal of Social Hygiene* continues both a demonstration and a service. A service to interested libraries, of which there are many, and a demonstration of coöperation by a national health agency.

Articles discuss the use of social hygiene material through the National Health Library, a state library, library of a social hygiene society, a large city library, a rural library, a rural church, a university library, a school of nursing, and medical libraries.

The issue includes numerous book reviews and bibliographies, and "Social Hygiene Bookshelf for 1936."

In *Journal of Social Hygiene*, 50 W. 50th St., New York, N. Y. June, 1936. *35 cents.*

From the Inside Looking Out—Objections to the use of those weasel words, "social disease," have several times been voiced by Marlen Pew. For years Mr. Pew has been editor of *Editor and Publisher*, the chief journal of journalism. On his personal page, "Shop Talk at Thirty," he said May 2, 1936:

The Public Health Service has just completed at Washington an annual conference of federal and state public health officers, one session of which was devoted to a symposium on the important subject of syphilis. A striking fact in this connection is that a number of metropolitan newspapers for the first time used the name of the disease in editorial discussions and news reports. It was fresh proof that newspaper editors generally recognize that the control of syphilis is important. No newspaper would refer to smallpox as an "eruptive disease." Yet it is just as indefinite to refer to syphilis as a "social disease" and this general practice, still followed by the major news associations and newspapers in general, interposes a real handicap to efforts of health authorities in securing the public support they should have.

Washington Daily News carried an editorial on the subject, in part as follows: "State health officers, at an annual conference in Washington, devoted a full day to discussion of the dread, widespread disease of syphilis. Here are some of the things the health officers said":

This was followed by a half dozen factual paragraphs.

Health Education in August Journal—*American Journal of Public Health*, August, 1936, includes the material noted below.

In "Modern Trends in Nursing Education," by Goodrich, note paragraphs on pages 764 and 765.

"Community Public Health Nursing in the Philippine Islands," by Dunham, pictures conditions and needs and how they are met (pages 771–777).

A thought stimulating paragraph by Henry Thomas Burke (page 785) in "Integrated Control of Occupational Diseases," by Sappington.

"Use of the Terms 'Sterile,' 'sterilize,' and 'sterilization'" (page 806) is addressed to advertisers, but may be useful to health writers and speakers.

"Venereal Diseases" (editorial, page 823) is preachment against preaching versus action.

Note, "Toward Preserving Public Health," by Patterson (page 841).

We hope that "Things in New Orleans You Will Want to See" (pages 843–847) will make more sure that you will be present at the 1936 meeting of the American Public Health Associa-

tion, and that you will use the hotel reservation blank on page 849.

New members of Public Health Education Section are listed on page 853.

Three health campaigns are mentioned on pages 856–857.

Christmas Seal Sale Publicity—It is announced that the publicity material for this year is being supplied by National Tuberculosis Association in 10 sections as follows:

Newspaper Features; Cartoons; Daily Reminders; Magazine Articles and Advertisements; Radio Scrips; Club and Radio Talks; Fillers (for Newspapers and Radio Stations); Sermon; Stunts and Suggestions; Miscellaneous. This last section contains 9 items among which is "Statistics—Up to the Minute," a recent compilation of data briefly worded, and should receive wide distribution among newspaper editors and speakers. . . .

Civil Service Exam in September—An "open competitive examination for field instructor in public health education" was held Sept. 19 for the Division of Public Health Education, State Dept. of Health, Albany, N. Y. The examination was conducted by the State Department of Civil Service.

Duties: Under direction, to supervise public health education programs with leaders of groups such as 4-H clubs, Boy and Girl Scouts, Home Bureaus, Parent Teachers' Associations, and other similar organizations; to promote and direct projects and programs in public health education in coöperation with district health officers, public health nurses, local health officers, and physicians; to address meetings and conferences on methods in public health education, and to devise new methods of disseminating accurate information on this subject; to prepare news releases, health courses, reports, and other publications; and to do related work as required.

Minimum Qualifications: Candidates must meet the requirements of one of the following groups: Either (a) graduation from a college or university of recognized standing with specialization in journalism or community organization and 3 years full-time experience in community organization and public health education involving the planning and execution of field health campaigns together with the direction of the work of others, including the preparation of material for use in newspapers, radio, exhibits, and motion pictures, at least 1 year of such experience preferably shall have been in the employ of a state, county, or municipal health department, and shall have included or been supplemented by 1 year of experience in newspaper work; or (b) a satisfactory equivalent combination of the foregoing education and experience. Additional credit will be given in rating training, experience and general qualification requirements for completed courses in public health or other college work which bears directly upon preparation for work in the public health field.

Subjects of Examination:

Written examination on the knowledge and skills involved in performing the duties, relative weight.............. 4

Training, experience and general qualifications, relative weight........... 6

Please send other civil service examinations in health education, and question lists for the same. We would like to display at New Orleans.

Hygeia, September, 1936 — Here are titles and topics, source material, and reprint material. *Hygeia,* 535 N. Dearborn St., Chicago, Ill.

Health examinations before marriage (what and why) . . . Undulant fever (origin and spread) . . . Uses of snake venom . . . Safety in the home . . . For the school lunch box . . . Vaccination of Napoleon's army . . . The physical superiority of college students . . . The play way to health and long life . . . William Crawford Gorgas . . . Home study . . . The passing of disease (30 years of medical progress) . . . Balancing the physical basis ("insurance" value of preventive medicine) . . . What you should know about cancer . . . Typhoid bacilli . . . Food, drug and cosmetic racketeers . . . The Martin Family vacation (testing the well; shallow wells and rural nurses) . . . New books on health . . . Healthgrams . . . Questions and answers.

In "School and Health":

What is adolescence? . . . Health lessons from real situations (the flood in Lowell, Mass.) . . . Planning your safety program in

September . . . Art in the service of health (the first of a series).

They "Say It With Pictures"—A full page of reproductions of newspaper clippings illustrates how Red cross chapters utilize varied activities and circumstances to provide pictures and text for newspaper use. See *Red Cross Courier,* Washington, D. C., Sept., 1936.

We would welcome similar specimens from health agencies. Good use could be made of such contributions for display at the Annual Meeting, and in this department of the *Journal.*

When Dietetics May Be Fun—Minnesota 4-H Club boys were asked what they liked to eat. *Farmer's Wife* presents the results for their girl readers. The article talks about "good eats," but a similar approach might be made through other groups of young people, and the "findings" could be served with an added dressing or sauce of dietetic application. It is one way to unconventionalize our health teaching.

Probably our fellow member, Carroll P. Streetor, *Farmer's Wife,* St. Paul, Minn., will send upon request a copy of this September, 1936, issue, containing "Girls, Here's What the Boy Friend Likes to Eat."

A Talking Slide Film—A new slide film is announced under the sponsorship of the American Social Hygiene Association.

The special subject of the production is syphilis, and the title is For All Our Sakes. Attractively phootographed, and accompanied by a voice recording of unusual variety and vividness, this new presentation should be decidedly effective as a means of informing the lay public, which it is particularly designed to reach.

The film and record (disc) have been prepared for use with any standard "talking slide" machine. In general this lecture may be shown to any audience at any time simply by telephoning the Western Union Telegraph Company, which handles the equipment and operation of such productions in the principal cities of the country. The Company's inclusive charge for this service is $10 per showing. The production can also be leased directly through the association by the day, week, month, or year. For terms and other details inquire at the association's office at 50 West 50th Street.

"Health Education for 4-H Clubs"—A 7 page mimeographed bulletin with this title has been issued by Coöperative Extension Work, Ithaca, N. Y. The pamphlet lists 3 steps in planning a county 4-H health program. Topics suggested for 1936–1937 are divided between discussion topics, and demonstration-participation topics.

An outline of teaching methods precedes paragraphs descriptive of the suggested topics.

Added is a page of "topics suitable for discussion with leaders and other adults."

The pamphlet is a coöperative project of the Public Health Education Division of New York State Department of Health. Address W. J. Wright, State Club Leader, Ithaca, N. Y., for a copy.

"Owing to the Increasing Demand"—What is your policy as to requests for printed matter from teachers and individuals, not health workers, living outside your city or state? The mention of publications in radio broadcasts, and the numerous mimeographed and printed reference lists which include mention of local and state educational material has increased the out of bound requests for single copies and quantities.

The Massachusetts Department of Public Health sends the following mimeographed statement:

In response to your request we are sending sample copies of the pamphlets desired, to be used for reference purposes. Owing to the

increasing demand for our printed material it is impossible for us to send additional copies outside the state. We would be glad to have these publications reproduced by local organizations wishing to use them if credit is given to this department.

Your own state department of health would probably be glad to supply pamphlets on health, or they may be obtained from the U. S. Public Health Service, or the Children's Bureau at Washington, D. C.

Why Not in the U. S. A. and Canada?—Something better than dolls in exhibits is mentioned in a letter from China, and illustrated in Sept., 1936, issue of *American Journal of Nursing*, 50 W. 50th St., New York, N. Y.

I was very much interested to read in one of the issues of the *Journal* of a nursing exhibition and especially of dolls representing the history of nursing. We tried a similar project but talent failed sufficiently to alter any dolls we could find, so in the end we made plasticine models. Some of the limbs were sadly out of proportion but we felt that on the whole the models could be voted a success.

Dolls in displays are likely to be distractingly "cute," or unconvincingly doll-like. Desirable substitutes are the plasticine figures (or other material used in the schools), or mounted and cut-out photographs or sketches.

They Believe in the Health Department—Says Dr. J. O. Nall:

Within recent months I have had occasion to talk with a number of representative citizens concerning the full-time county health department and the activities of its personnel—health officer, public health nurse, and sanitary inspector. I have made no special effort to pick the people with whom I talked, other than to select persons whose family life or business would naturally bring them into contact with the county health workers.

Among those with whom I talked were a farmer, a dairyman, a country store keeper, a widowed mother with three children in school, a rural school teacher, a restaurant operator, a policeman who had killed several dogs suspected of being mad, a soda fountain clerk, a woman suffering from active tuberculosis, and a citizen of a county which does not have a full-time county health department. One general question was put to each of them: "Have you or your family benefitted by the full-time county health department; if so, how?" Some replied that they could not think of any special benefit other than that their children had been given "shots" at school against diphtheria, smallpox, and typhoid fever. Others immediately mentioned activities of the health authorities from which they had derived definite and specific benefit. These included the 10 enumerated above.

Then follows the testimonies of "The Farmer," "The Dairyman," "The Widowed Mother with Three Children," "The Soda Fountain Clerk," and others, as reported in *Bulletin*, State Dept. of Health, Louisville, Ky. Aug., 1936.

The Farmer said:

"I was opposed to smallpox vaccination until the health department was organized here. I had refused to have my children vaccinated because I couldn't see that vaccination made any difference. Then, one day, the health officer made a special trip to see me and talked to me the better part of the afternoon, explaining the history of smallpox and smallpox vaccination and showing how it had controlled the disease. He convinced me that I knew nothing about smallpox or vaccination against it. I decided that if the health officer could afford to spend so much time talking to me about vaccination, I could afford to change my mind." He added, with pride, that he had since convinced several of his neighbors of the need for general vaccination against smallpox and helped to secure the vaccination of every school child in his district. . . .

Has anyone else carried out this fine idea?

DATES AHEAD

Use past events to talk for you, as well as the present, and the future.

National historical dates and local dates of many types offer chances for dignified tie-ups with health ideas or health organizations. Editors will welcome your good ideas, especially when they bring new angles on some

of the over-worked dates which cannot be ignored.

Fire Prevention Week, Oct. 4–10, 1936, will come a year from now at about the same time. Make it a date even if it is too late to make use of it this year. See "News Almanac for Social Work" (Community Chests and Councils, 155 E. 44th St., New York, N. Y. *50 cents*) for specific suggestions.

Columbus Day, Oct. 12, may be a time for reporting "discoveries" in the health field, possibly in local conditions as suggested in the "News Almanac." How about a "Health Columbus" in your city?

Association of Junior Leagues (see the "Almanac") birthday, Oct. 18, may be a time for some testimony to the help to local health activities given by the local league. Or, a time to suggest that the league consider some health education activity.

Most important of all will be the sessions of Public Health Education Section at New Orleans, Oct. 20–23, 1936.

Girl Scout Week, Oct. 25–31, includes Saturday as Health Day.

The 1936 Mobilization for Human Needs includes numerous national publicity features intended to support the local chest money raising activities throughout the country. In most cities health agencies have a definite stake in these campaigns.

American Education Week, Nov. 9–15, offers an opportunity for health agencies to participate.

Red Cross Roll Call starts Nov. 11 when Red Cross health activities should receive special attention.

Annual celebration of the founding of The National Committee for Mental Hygiene, Nov. 12, is a time for accenting the new day for the mentally sick. Is your city doing its part?

The unlucky day made "lucky," Friday, Nov. 13. The "Almanac" suggests a human interest story about some success in health service, begun or ended on this day.

National Book Week, Nov. 15–22, may be a time for playing up the health service of books, or the health books available at the health department, or the health books to be found in different local libraries, or the giving of health books to institutions and centers where they might get a wide reading, or a display of health books at the public library or in a book shop.

The first local organization of what later became known as the Y.W.C.A. was founded Nov. 24, 1858. Another opportunity for health agencies to devise ways of expressing appreciation of the health activities of a local organization.

Thanksgiving Day, Nov. 26, suggests contributions toward a healthful Thanksgiving, or publicly expressed thanks for gains in health conditions and health activities.

Christmas Seal Sale, opening Nov. 26, means both money raising and health education.

See the back pages of this issue of the *Journal* for list of conventions and other events, many of which offer opportunities for local health education purposes.

If you have suggestions on any of the above please write to us. If you seek suggestions, or if you don't fully understand any statement in the foregoing, please write.

BOOKS AND REPORTS

An American Doctor's Odyssey—*By Victor Heiser, M.D. New York: Norton,* 1936. 544 pp. Price, $3.50.

When, on May 1, 1898, Admiral Dewey sailed into Manila Bay, he added enormously to American prestige, as well as territory to America, but he also gave to America the grave responsibility of caring for a rather heterogeneous population scattered over an archipelago extending over a thousand miles from north to south, a population which, as regards advancement in modern ideas, had slumbered peacefully for many years under Spanish rule. He gave to us a people among whom many of the notable scourges of the world were endemic. Here was a laboratory for investigation and rich ground for field trials. Without disparaging the work of sanitarians and scientists in other parts of the world, it is not too much to say that the demonstration given in the Philippine Islands stands as a monument to preventive medicine.

The man who had much to do with every phase of this regeneration is the author of this book, which is a record of his achievements. After some preparation in the immigration service of the United States in Naples, he was appointed Chief Quarantine Officer of the Philippine Islands, and later Director of Health. The officers of the American Army, upon whom this duty devolved from the military standpoint, had had little experience in dealing administratively with tropical diseases. In 1902, Drs. Gorgas and Heiser were sent to the International Congress on Medicine in Cairo, where they met officers of many nations who had experience in the administration of health in the Orient and tropics. They were met everywhere with the reiterated statement that it was a waste of time to try and sanitate Orientals, who wished to be left to their old unhealthy habits. Life was cheap in the Orient, and apparently it had not occurred to the employers of colonial labor that much money could be saved by improving the health of their employees and in lessening the death rate.

The conditions which confronted Dr. Heiser were anything but conducive to optimism—years of insurrection, discontent and discouragement, inefficient government, and a declining scale of living, with little hope for the future. Plague was rampant. The morgue was piled with dead bodies of cholera victims. Forty thousand were dying each year from smallpox. Tuberculosis caused 50,000 deaths a year. Sufferers from beri-beri numbered tens of thousands. Every other child died before its first birthday—the highest infant mortality rate in the world. There were 10,000 leprous men, women, and children. Venereal diseases were widespread. There was much insanity. The different types of malaria were everywhere. Manila was overcrowded. Six to eight slept in rooms hardly large enough for one. There was an antiquated and polluted water system built by the Spaniards, but there was no reservoir, not a pipeline, and not an artesian well. There were practically no sewer systems. The vilest class of food products was shipped into the country; perishable foods were sold from the ground; no proper inspection

of animals was made before slaughter, and diseased cattle were regularly marketed. The people were strongly imbued with superstitions and traditions, apparently contented with their lot and resigned to their illnesses. In spite of this discouraging picture, Dr. Heiser set for himself the goal of saving 50,000 lives a year.

Chapter after chapter gives accounts of how one bad condition after another was met, how one disease after another was conquered, how superstitions were overcome and hope for the future was instilled into the inhabitants of the many islands.

The head of one chapter, "Washing up the Orient," tells the story. America was literally "Washing up the Orient."

This book might well serve as a textbook on preventive medicine. A good history of each disease is given, and the methods of handling it are described. How anyone can read of the results accomplished and doubt our control over epidemic diseases, even under the difficult conditions described, passes understanding. Argument is not needed. The facts speak more loudly than language. When 300 savage Moros, fully armed, come and demand vaccination because of their observation of the freedom from smallpox enjoyed by their fellow men who had been vaccinated, we feel convinced that there is hope for any part of the world in preventive medicine.

This book would also be useful as a study in sociology: It is a demonstration that philanthropy pays dividends. By 1914, *the great pestilences had been* brought under control. The Filipinos as a nation were advanced in convalescence, and a permanent health organization was established.

Among the difficulties encountered, not the least were those due to various religions, a striking example of which is given in the replies of a Mohammedan chief to a medical man:

"What's your death rate?"

"It is the will of Allah that all die; some die young, some old."

"What's your number of births?"

"Allah alone can say."

"Is your water safe and potable?"

"History records no death from thirst."

"What is the hygienic condition of your village?"

"Allah sent Mahomet who proved the truth with fire and sword. Now, Lamb of the West, cease your questioning. It can do you or others no good."

The book is most entertainingly written. It contains many anecdotes, some of which test one's credulity. Certainly no story loses anything in the telling. There is Ibayat, rising sheer from the sea, surrounded by a circular rim which not even a goat could climb, and up which those trying to land must be hauled in a basket suspended by a vine, yet the inhabitants raise cattle and export them, getting them to ships by forcing them over this precipice into the water. We keep wondering how the original inhabitants and the original cattle reached this unapproachable haven!

The whole book tells the story of remarkable achievement, and demonstrates to us what can be done by knowledge put into action by an able, alert, and aggressive man backed by illimitable funds. The author has an apt way of summing up with succinct sentences which are worth pages of argument, for example: "There are very few anti-vaccinationists now in the Philippines. Most of them have died of smallpox." The Tamils, "with *hardly a smile in the entire race*" because of hookworm, were given successful mass treatment, and "At last the Tamil smiles."

There are certain statements which are unfortunate, especially as the book is for the general public. The author speaks of the "Pasteur treatment for hydrophobia," which will give the layman an entirely wrong impression. We

are told that the Negro has an undivided cartilage at the end of the nose, and that this peculiarity, which extends even to octoroons, is a sure test of Negro blood. The authority for this statement has not been found. It is not true of the Negro in this country. The identity of yaws with syphilis is not recognized, in spite of the successful treatment with salvarsan.

The book can be recommended from many standpoints. The interest of our readers lies chiefly in its public health aspect. Others will find in it a book of travel and adventure; still others a history of the races of the world. It is boundless in its interests; there is something for practically every class of reader. MAZŸCK P. RAVENEL

Don't Be Afraid—*By Grace Adams. New York: Covici-Friede*, 1935. 188 pp. Price, $2.00.

An interesting and instructive book from the author of *Your Child Is Normal.* Fear as a protective, biological mechanism is not the crippling emotion most people conjure up at the mention of the word. Fear has its place and uses, but fear of fear has no rightful entry in our everyday psychology. Odd quirks, foibles, fads, and phobias are mental bed-fellows with intelligence, discretion, and quite often, genius. Dr. Adams lists a group of the world's famous and their less-famous parataxic reactions.

The psychologically strong are not so because they lack weaknesses but because they have overcome or used them to advantage. The bogie of superstition is born in the infancy of the individual and in the untutored, primitive emotions of the race.

The chapter on The Modern Conscience gives valuable advice which might be stated tersely—know thyself. Self-knowledge breeds respect and consideration for others and fosters understanding, tolerance, and group adjustment. Fear loses much of its paralyzing effects when brought out into the open and discussed in the simple, sane way which we have come to expect of the writings of Dr. Adams.

MAURICE A. R. HENNESSY

My Life and Work—*By Adolf Lorenz, M.D. New York: Scribner*, 1936. 362 pp. Price, $3.50.

Dr. Adolf Lorenz has written an autobiography which is interesting and at the same time most revealing. Its interest lies in the well sustained narration of the experiences of a life of accomplishment, which, starting in a humble peasant cottage in Silesia, reached its climax in the capitol city of Vienna with the title of Professor Extraordinarius, the Order of Hofroth, and world fame. Dr. Lorenz writes most interestingly and intimately of all phases of his struggle from obscurity to international prominence; but only in those chapters dealing with his early life and struggle for an education does he fill in the details of his growth and progress. The years of his professional development are painted in bold strokes and give but a vague picture of the steps by which a local practitioner of bloodless surgery became a world figure. It would seem, however, from what is revealed of the struggling boy and medical student that an alert mind, a firm determination to succeed, backed by energy and perseverance, self-confidence, and a winning personality were the materials with which a most distinguished career was built.

The revealing side of the book lies in its frank egoism and egotism. That Dr. Lorenz gave himself undue supremacy in his thoughts is evident from the very beginning of the book; that he gave himself undue prominence in speech becomes a conviction as the last word is read. That Dr. Lorenz contributed greatly to the advancement of orthopedic surgery is unquestioned.

That he was a super man, accomplishing cures that were beyond the skill of others is open to debate. Yet his words can leave no other impression than that he felt that he stood out above all others of his guild. This weakness in a really great character is demonstrated by the fact that in a book of 353 pages, only 108 of them are devoted to his early life, his development, and his arrival at his goal of professorship. The remaining pages are given over to the description of his accomplishments at home and abroad.

Dr. Lorenz in his life story reveals a very human personality. He shows himself a strong and sturdy character, who in spite of his naïve vanity, compels respect by his determination to succeed, his ability to do so, and his contributions to medical progress. That he had a deep sympathy for those physically handicapped is shown by his great kindness toward crippled children and his ever ready willingness to help them to the limit of his ability whether they were princes or paupers. That he had a strong heart is evident, for deprived of a promising career in general surgery because of his sensitiveness to carbolic acid, the then universal antiseptic, he built on its ruins a brilliant career in bloodless surgery. The life of such a man is well worth knowing. It is an interesting story of accomplishment and success in a country and in times when the low born and poor had but little opportunity for advancement, and so it has lessons to teach as well as pleasure to offer.

FRANK D. DICKSON

The Jew in Science—*By Louis Gershenfeld. Philadelphia: The Jewish Publication Society of America*, 1934. 224 pp. Price, $2.75.

One cannot merely review this book from the viewpoint of composition and content, but is rather impelled to ask, "why was it written?" The author anticipates and answers the query, by saying that it had been his hobby to collect notes on "the history of science, Judaism, and scientists." The publication of the accumulated material, however, the author warrants on the basis that "there are some Jews of high standing, in addition to non-Jews who claim that the Jew does not share or do well in the sciences."

To counteract this impression the author devotes 87 pages to The Beginning of Civilization; a Brief History of the Jewish People; Science and the Jewish Scientist until the Dark Ages; The Dark Ages until after the Death of Maimonides; Other Incidents during the *Middle Ages and until the Nine*teenth Century; Renaissance. The remaining 138 pages of the book are almost entirely devoted to an uncritical listing of the names of Jews, half Jews, and converts, in the various divisions of science.

The historical portion is sketchy to the point of being a catalogue of names and dates, with only thin circumlocutions to tie them together into the semblance of a narrative. The second portion would make an excellent "index expurgatorius" for an American Hitler.

There is something incongruous in a work devoted to the Jew in Science, which carries the subject beyond the late Renaissance and into the modern period. It is the boast of learned men that science is international, that its devotees form a true brotherhood, that the accidents of birth, color, race, religion, are without note in its realm. There are only scientists, not Christians *in* science, Mohammedans *in* science, Jews *in* science.

Unquestionably the scientist does not shed his innate religious and racial qualities, as he enters his "laboratory." Metchnikoff, a half Jew, half Slav, differed in his personality, and in his approach, from his Breton, Catholic,

predecessor, Pasteur, who differed radically from his contemporary, Robert Koch, the German. There is a history to be written on the influence of the racial characteristics of the scientists on the development of science. The impediment is the definition of the meaning of race, an impediment greater as it pertains to the Jew, than to say the German, the French, or the Italian.

The Jew in Science does not deal with the unique contributions which Jews made to science, *because* they were Jews. It merely lists the names of Jews in science, and tells very briefly under what adverse circumstances they pursued their scientific work. It is too condensed to serve as a history. It may perhaps convince some of its readers, who need that conviction, that the Jew does share in, and does well in the sciences. IAGO GALDSTON

Plague. A Manual for Medical and Public Health Workers—*By Wu Lien-Teh, M.D., J. W. H. Chun, M.D., R. Pollitzer, M.D., and C. Y. Wu, M.B. Shanghai, China: National Quarantine Service,* 1936. 547 pp. Price, $4.00.

There has come to us from China a book on plague which is quite unusual. The senior author was formerly Director of the Manchurian Plague Prevention Service, and is well known for his writings, especially those on the various aspects of plague, including its prevention. Drs. Chun and Pollitzer were formerly associated with the senior author in the Manchurian Plague Prevention Service, and are now in the Quarantine Service at Shanghai. Dr. Wu is connected with the National Quarantine Service and is Senior Quarantine Officer at Shanghai. All four authors have had extensive experience with plague from every standpoint, and the book they have produced is authoritative.

The history of the disease, hosts and carriers, and epidemiological factors are from the pen of the senior author; bacteriology, immunology, pathology, and laboratory diagnosis are by Dr. Pollitzer; insect vectors, prophylaxis and management of epidemics, and ship-borne plague are by Dr. Wu; while Dr. Chun has been responsible for the clinical features, therapy, and personal prophylaxis. They have evidently worked in close association and there is an evenness of treatment sometimes missing from a book produced by several authors.

The authors state that they have kept constantly in mind the needs of medical and public health workers, and while some material of highly technical nature has been included on account of its value to advanced students, their chief object has been to provide a practical guide for the prevention and treatment of plague. The many people all over the world who are familiar with the writings of the authors need not be told that a thorough canvass has been made of every source of information.

It is held that the oldest and most active of the endemic areas of the world are within or adjacent to the Central Asiatic plateau, which constitutes the ancestral home of plague. The idea that North Africa and areas in Eastern Central Africa were the early foci is held to be without sound foundation.*

The authors believe that, taken as a whole, the changes are favorable for a continued survival of the plague virus. Under favorable conditions, infection may persist for long periods in one place. Rats are not given to extensive active migration, but are passively carried by ships and other means of communication to very distant points. Infected fleas may also play a significant part, being carried by man and certain

* This is discussed at length and in detail in *Manchurian Plague Prevention Service Memorial Volume*, 1934.

types of merchandise to widely scattered regions. In areas in India which experience regular outbreaks during the plague season, the disease persists in rats during the off-season in limited localities. At present there are 27 principal foci, most of which are in the East, although the Hawaiian Islands and the United States contain foci of infection. In the Rocky Mountain region of the United States a wild rodent plague, to which the name "selvatic" plague has been given by Jorge, shows a disquieting tendency to spread and new foci have been found in this district very recently.

There is a general retrogression of the present pandemic. Curiously enough, Europe, which in the past has been a favored home of pandemics, has become almost impregnable to the current wave of infection. The authors hope that improved standards of living and housing, together with the laws of nature, will render other regions unfavorable to major inroads of plague.

From our standpoint, the epidemiology of the disease is the most important feature, since upon this depend prevention and the management of epidemics. General prevention of the bubonic type of the disease is based upon its relation to rodents and their ectoparasites. Man's contact with the infection depends chiefly on contact with the rat and its fleas, and his chance of escape from the scourge is conditioned upon the effectiveness of the campaign against these vermin. While the authors make this broad statement, they recognize fully the rôle of the ground squirrel in California and other rodents in some parts of the world, especially, for example, the tarabagan of Mongolia and Transbaikalia, and the susliks of South-Eastern Russia. The authors agree with Deprat that "the doctrine of rat and flea guilt forms the keystone of the arch of international sanitary defense against plague," but also with Heiser, who holds that the "control of the disease depends upon preventing rat-fleas that have bitten plague-infected rats or human beings from biting man." They point out that the natural spread of the disease is greatly retarded because rat-fleas do not bite man by choice, but only after failure to find their proper host.

The book is profusely illustrated with half-tone plates, maps, charts, figures, and some color plates. All names of persons, diseases, parasites, and many illustrations are given in the Chinese characters as well as in English. The scientific names of insects and rodents are also given in italics. There are interesting tables, one giving a list of the pestilences in China from 224 B.C. down to the present time. Each chapter is followed by a well selected bibliography. Altogether, it is hard to speak too highly of this book. All of the authors write exceptionally good English. The book is up to date, even including some references in 1936. The printing and binding are excellent.

MAZŸCK P. RAVENEL

Hospital Organization and Management—*By Malcolm T. MacEachern, M.D. Chicago: Physicians Record Company*, 1936. 944 pp. Price, $7.50.

The increasing relationships of hospitals with public health work render this book of considerable interest to health administrators. Dr. MacEachern, as director of hospital activities of the American College of Surgeons, has had unique opportunities to become familiar with hospitals throughout the United States and Canada, and he has drawn upon his wealth of experience in compiling this substantial handbook for executive officers of medical institutions.

After a brief review of the history of hospitals and of the problems of planning and building new ones, the general

organization of a hospital is described. A series of chapters is then devoted to the professional and administrative departments. The book enters into technical detail of practical value in the day's work of the administrator, but does not fail to enunciate general principles also. Considerable attention is given to the community relations of the hospital, and to methods of public education. Relationships with public health departments fill only a few pages. Much more might have been said on this subject in connection with the laboratory and out-patient services. Care of communicable diseases is dealt with and the development of satisfactory facilities for them in general hospitals. The numerous copies of forms, "standards," and standing orders are a useful feature of the book.

Little attention is given to the special problems of the small hospital in the town or rural community, a matter to which many health officers are now giving considerable thought; but it must be borne in mind that this is a handbook of institutional management rather than a guide to public policy.

MICHAEL M. DAVIS

Outline of Town and City Planning—*By Thomas Adams. New York: Russell Sage Foundation,* 1935. 368 pp. Price, $3.00.

This volume is largely based on a course of lectures delivered to students of the Department of Architecture of the Massachusetts Institute of Technology over a period of 11 years. A brief description is given in the introduction of the meaning and scope of city planning in relation to modern practice. Part I reviews the character of early efforts in the planning of cities down to the middle of the 19th century; Part II describes developments in the United States and other countries since about 1830, concluding with a discussion of modern methods and aims, and of some considerations relating to the future; while the Appendix summarizes many aspects of the subject which the city planner may have to consider. Logical arrangement of subject matter and enlightening information regarding community planning procedures, characterize this volume which should be a useful source book for city officials, including health administrators, as well as those specifically engaged in planning and zoning departments.

City and town planning is defined as a science, an art, and a movement of policy concerned with the shaping and guiding of the physical growth and arrangement of towns in harmony with their social and economic needs.

> We pursue it as a science to obtain knowledge of urban structure and services and the relation of its constituent parts and processes of circulation; as an art to determine the layout of the ground, the arrangement of land uses and ways of communication and the design of the buildings on principles that will secure order, health, and efficiency in development; and as a movement of policy to give effect to our principles.

The suggestion is made that the tempo of traffic that has arisen in the cities of all countries has caused traffic problems to be overemphasized in town plans; but it is being more and more realized that solution of the evils of congestion by means of communication cannot be achieved without orderly control of building designs, uses and densities, and the provision of ample spaciousness for health and recreation in the surroundings of homes and places of work. Furthermore, the plan of a new town may, on the whole, be approached without the limitations which affect replanning. "Much that can merely be mended in the existing community can be prevented by foresight in the new community." The author suggests the term "civic design" to distinguish the art of city planning from the act or machinery of making plans, and emphasizes that a plan is only a

means to an end, and that end is a stable and well balanced physical structure so designed as to secure health, safety, amenity, order, and convenience, and, generally, to promote human welfare. IRA V. HISCOCK

Your Germs and Mine: The Story of Good and Bad Microbes—*By Berl ben Meyr. Garden City: Doubleday, Doran,* 1934. 389 pp., 34 ill. Price, $2.75.

The title page contains a quotation from Dr. Logan Clendening; the book is dedicated "To Koch's Bacillus)"; acknowledgments are made to 65 persons, including novelists, columnists, and an authority on the psychology of sex; and there is a foreword by Dr. Albert Einstein. In a foreword of his own, the author explains that while "the human drama lurking within bacteriological research already has established itself as a theme in modern literature," he proposes to portray "the critical part played in human affairs by the bacteria themselves."

With so much said by way of introductory explanation, one would expect to find some assurance that the information is authentic, but none is given. Nor are there references in the text by which the lay reader can confirm or follow further the information set forth. Inasmuch as the author does not attempt to promote any new theory or upset any established fact, but merely to interpret what may be regarded as orthodox doctrine, perhaps this does not greatly matter.

Among the 13 chapters are the following: The Nature of Microbes; The Microbes in Dust, Air, Sewage, and Water; Milk and Its Microbes; Microbes in the Home; and Microbes in the Prohibition, War and Other Industries.

About a dozen diseases are taken up and dealt with specifically. Here there are a few minor slips. Turning to Chapter VIII, the reader finds the statement that "practically every urban center in the United States has a crop of typhoid fevers in the late summer and autumn," due to infection contracted while on vacation, but on the next page a statement appears to the effect that among 81 of the larger cities there were 9 without a single typhoid death for 1 year, and 6 with a population of one million or more with less than 2 per 100,000.

The author declares that typhoid carriers "probably have a chronic infection in the intestinal or genito-urinary tract, which continues to discharge virulent microbes," but says nothing about infections of the gall bladder.

In the section on water supplies there are also several slips, as where inspection of the sources is omitted from an account of the ways in which the question of the purity of a water supply can be estimated. And in the matter of water analysis, the great significance which may attach to the quantitative determination of chlorine seems to be misunderstood by the author.

Intended for the popular mind, there is little in this book that the health officer of today has not learned in his days of training or cannot readily get from authoritative sources in his library.

GEORGE A. SOPER

Bibliography in Health Education for Schools and Colleges—*By Mary Ella Chayer, R.N., A.M. New York: Putnam's,* 1936. 100 pp. Price, $1.50.

"The purpose of this bibliography is to offer to the classroom teacher and to the special teacher or health education supervisor a wide variety of source materials from which to select library materials."

Though this is a fair bibliography of the field of health education, there seem to be certain serious deficiencies. In

the field of play, it would be interesting to know why Joseph Lee's *Play in Education,* a text 13 years old, was chosen in preference to Mitchell and Mason *The Theory of Play,* modernized and published in 1934.

The necessarily brief descriptions of content are in some cases seriously misleading.

Why was the outstanding periodical in this field, *The Journal of Health and Physical Education,* omitted from the list?

The classification of texts has been carelessly done. One that has received several state and numerous city adoptions as a high school text is listed as a college text—advanced—and the name of one of the authors is omitted.

There is probably no other field of publication in which the work is so poorly done as in that of bibliography.

CHARLES H. KEENE

How Life Begins—*By George L. Bird. Chicago, Ill.: The Book House for Children,* 1935. 117 pp. Price, $1.00.

Explaining the beginning of life to children is still one of the most difficult tasks the parent faces. Nor do books written to aid the parent in this duty always prove of much assistance. It would seem, however, that the one under review might furnish the needed aid, especially if the children to be instructed have some acquaintance with country life.

The plan of the book is a simple one. Starting with the beginning of plant life as represented by the yucca, it progresses in eight chapters through bird and lower animal life to the story of reproduction in man. The subject is handled simply, the stories which carry the information are interesting, natural and appealing. Parents and children both will appreciate this book intended for children from 6 to 10 years of age.

M. E. CHAMPION

Tuberculosis—*By Gerald B. Webb, M.D. XVI of the Clio Medica Series, edited by E. B. Krumbhaar. New York: Hoeber (Medical Book Department of Harper),* 1936. 205 pp. Price, $2.00.

This little volume is a valuable addition to the library of tuberculosis in that the author presents in terse readable form a compact historical survey of his subject that makes the facts readily and entertainingly available to the general practitioner, the medical undergraduate, and the interested layman. A monotonous chronological presentation is avoided by division of the history into epidemiology, the knowledge of the ancients, the middle ages, contagion, pathology, the tubercle, the tubercle bacillus, immunity, diagnosis, treatment, rest treatment of tuberculosis, climate, sanatoria, and legislative prophylaxis. Apt quotations preface and conclude the separate chapters. Certainly the wise and busy physicians cognizant of the value of a historical background in treatment and diagnosis must spare a short hour or two for this little handbook and possibly a second period for a profitable re-reading.

LAWRASON BROWN

Stamp Out Syphilis!—*By Thomas Parran, M.D. Survey Graphic, July, 1936. Reprints are available at 10 cents per copy. Also enlarged facsimiles of pictographs. Quantity rates from Survey Associates, 112 East 19 St., New York, N. Y.*

Following closely on the list of "Musts" in public health work attributed to Surgeon General Thomas Parran of the Public Health Service, comes a striking article by him featured in the *Survey Graphic* which is being widely distributed throughout the country.

The writer says that syphilis bids fair to become the great American disease, though the figures given indicate that

it may have already taken this position. He scores our apathy and the "hush-hush" policy which we have followed, to which he attributes a large part of the spread of the disease. He tells of "Damaged Lives," an excellent moving picture adapted from the German by the American Social Hygiene Association for educational purposes, yet its public exhibition was forbidden in New York State, and only in New England and a few states could it be shown freely.

After a description of existing conditions, he states positively that our ability to control syphilis is greater than that for tuberculosis or typhoid fever, both of which diseases we have controlled to an extent hardly believed possible a few years ago. He backs this statement by the experience of Sweden, Norway, and Denmark, with a combined population nearly equal to that of New York State, yet all told they have about 1,600 cases of syphilis a year, while in New York State, exclusive of the City, last year there were 21,984 cases under treatment. In New York City, there were 1,836 new cases in one month. In the whole of Sweden, with practically the same population, only 431 occurred the entire year. While the Scandinavian countries are outstanding in their control of this scourge, America seems to be behind a number of other countries in many administrative features. Various methods of case finding and early control are discussed, as are legislation and education. Dr. Parran holds that the control of syphilis is not the business of the public health officer, the physician, and social worker only, but the whole people must be interested and take an active part. He lays down 5 things which obviously should be done, and ends by saying: "Syphilis must be the next great plague to go. We must attack it now."

ASSOCIATION NEWS

SIXTY-FIFTH ANNUAL MEETING

NEW ORLEANS, LA., OCTOBER 20–23, 1936.

Meeting Headquarters, Municipal Auditorium
Residence Headquarters, Hotel Roosevelt

For the Preliminary Program, Railroad Fares, Hotel Rates, and Post-Convention Tour, see Supplement to the September *Journal*

ALL is in order for the 65th Annual Meeting, New Orleans, La., October 20–23.

The scientific program is complete. The Local Committee has arranged for entertainment and inspection trips. More than forty applications for scientific exhibit space have been accepted. Special trains have been set up from principal cities for travel with pleasant companions. The post-convention tour to Florida and Havana is rapidly organizing. In brief, the various Annual Meeting committees, the City of New Orleans, and the convention management await the large audience which the 65th Annual Meeting will attract.

A 24 page supplement conveying full Annual Meeting information, including program, hotel and railroad rates, train schedules, and a summary of the Florida and Havana tour was bound in the September *Journal.*

NO RAILROAD IDENTIFICATION CERTIFICATES THIS YEAR

It is expected that winter rates to New Orleans will be in effect as usual October 1. Since these are lower than convention fares and are public tariffs, no identification certificates are needed for travel to New Orleans. **Consult your local ticket agent for the best rates prevailing in your territory.**

INSPECTION TRIPS AT NEW ORLEANS

Tuesday, October 20, 2:00 P.M.

Trip to Huey P. Long Bridge, New Orleans Water Purification Plant and New Orleans Sewerage and Drainage System.

Wednesday, October 21, 8:00 A.M.

Trip to U. S. Public Health Service Leprosarium at Carville, La. Two hours of inspection there. Continue to Baton Rouge, luncheon at Louisiana State University Cafeteria, visit to Louisiana State University Campus and State Capitol Building. This trip covers 180 miles and occupies a full day.

Wednesday, October 21, 1:00 P.M.

Visit to Louisiana State University Medical Center, Tulane University Medical School and Charity Hospital, New Orleans, La.

Friday, October 23, 2:00 P.M.

Visit to City and State Health Departments, including Laboratories, Bureaus of Vital Statistics, Sanitary

Engineering, Epidemiology, and Parish Health Administration.

Friday, October 23, 1:00 P.M.

Visit to U. S. Marine Hospital and Quarantine Station.

The Inspection Trips Committee is prepared to arrange special trips for limited numbers to local points of interest upon request.

ENTERTAINMENT AT NEW ORLEANS

The Entertainment Committee, under the chairmanship of Dr. A. L. Fossier, announces that a ball " A Night in Old New Orleans " is planned to follow the opening General Session on Tuesday, October 20. There will be costumes appropriate to the times, Negro mammies to serve the guests, and all the arrangements in traditional New Orleans style. Refreshments will be served.

On Wednesday, October 21, at 3:00 P.M., a trip through the French Quarter with guides is scheduled. This will be followed by tea at the " Court of Two Sisters."

An automobile sight-seeing trip throughout the city takes place on Thursday, October 22, starting at 3:30 P.M.

Dancing will follow the banquet on Thursday evening.

Golf privileges have been secured from various golf clubs.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Ralph H. Allen, M.D., Ruston, La., Director, Lincoln Parish Health Unit

Joseph E. Brodie, M.D., 5 Oakhaven Court, Greenwood, S. C., Greenwood County Health Officer

C. S. Cotlin, Jr., M.D., C.P.H., Box 208, Wetumpka, Ala., Elmore County Health Officer

James T. Duncan, M.D., 351 Beale Ave., Wooster, Ohio, Acting Health Commissioner, Wayne County

Thomas G. Faison, M.D., Winton, N. C., Hertford County Health Officer

Henry C. Gahagan, M.D., Coushatta, La., Director, Red River Parish Health Unit

Marshall E. Groover, Jr., M.D., Box 447, Quitman, Ga., Brooks County Health Officer

Lucius W. Holloman, M.D., Marksville, La., Director, Avoyelles Parish Health Unit

Matt F. Houston, M.D., Houma, La., Director, Terrebonne Parish Health Unit

Fritz A. LaCour, M.D., Crowley, La., Assistant Director, Acadia Parish Health Unit

Raymond F. McAteer, M.D., 4 Narragansett Court, Narragansett, R. I., Director, So. District Health Unit

Bernard T. McGhie, M.D., Toronto, Ont., Canada, Deputy Minister of Health

Peter F. Murphy, M.D., Alexandria, La., Acting Director, Rapides Parish Health Unit

Leland E. Powers, M.D., Port Angeles, Wash., Clallam County Health Officer

A. Einar Rietz, M.D., Vasagatan 6, Stockholm, Sweden, Medical Officer of Health

John Schreiber, M.D., Vidalia, La., Director, Concordia Parish Health Unit

W. K. Sharp, Jr., M.D., U. S. Marine Hospital, New Orleans, La., Regional Consultant, U. S. Public Health Service

Arthur M. Shelamer, M.D., C.P.H., State Dept. of Health, Montgomery, Ala., Field Adviser in County Organization

Hubert S. Smith, M.D., P. O. Box 245, Thibodaux, La., Director, Lafourche Parish Health Unit

Lewis C. Spencer, M.D., Harrisonburg, La., Director, Catahoula Parish Health Unit

Waldo L. Treuting, M.D., Box 311, New Roads, La., Director, Pointe Coupee Parish Health Unit

William E. Van Landingham, M.D., P. O. Box 758, West Palm Beach, Fla., City Health Officer

John M. Whitney, M.D., Jennings, La., Director, Jeff Davis Parish Health Unit

Frank A. Williams, M.D., Franklinton, La., Director, Washington Parish Health Unit

John E. Worden, M.D., 215 N. Carson St., Carson City, Nev., State Health Officer

Laboratory Section

Milward Bayliss, Ph.D. University of Nebraska Medical College, Omaha, Nebr., Instructor, Bacteriology and Public Health
Ruth Castles, State Dept. of Public Health, Nashville, Tenn., Laboratory worker
Herbert W. Emerson, Pasteur Institute, University of Michigan, Ann Arbor Mich., Director
William A. Feirer, M.D., D.Sc., Glenolden, Pa., Director, Mulford Biological Laboratories, Sharp & Dohme
Harley J. Morris, P. O. Box 265, Meadville, Pa., City Bacteriologist
Arthur W. Tallman, P. O. Box 376, Johnstown, O., Director, Hixson Laboratories, Inc.

Vital Statistics Section

Willis C. Beasley, Ph.D., U. S. Public Health Service, Washington, D. C., Assistant Chairman, Health Inventory Operating Council
Margaret Chisholm, 532 Third Ave., Lewiston, Ida., Department Clerk, Nez Perce County Health Dept.
Douglas N. West, 408 Medical Arts Bldg., Atlanta, Ga., Supervisor, Georgia Rural Health Survey Analysis, U. S. Public Health Service

Public Health Engineering Section

Tilden D. Adkins, 605 N. Patterson, Valdosta, Ga., District Engineer, State Dept. of Public Health
Earl B. Barnawell, Box 186, Thomaston, Ga., District Supervisor, Malaria Control and Community Sanitation, U. S. Public Health Service and State Dept. of Public Health
William W. Brush, 24 W. 40 St., New York, N. Y., Editor, *Water Works Engineering*
Arthur H. Herberger, C.E., 200 W. Merrick Rd., Freeport, N. Y., Junior Sanitary Engineer, Bureau of Marine Fisheries
Juan A. Hernandez, C.E., Instituto Finlay, Havana, Cuba, Civil Engineer, National Sanitary Engineering Dept.
Fred R. Ingram, 216 Lyon Bldg., Reno, Nev., *Sanitary Engineer, State Board of Health*
Walter J. Shea, 327 State Office Bldg., Providence, R. I., Chief, Division of Purification of Waters, State Dept. of Public Health

Food and Nutrition Section

Edmund St. J. Baldwin, 110 Hudson St., New York, N. Y., Supervisor, Bureau of Sanitary Control, Borden's Farm Products
Cassius L. Clay, 422 Chartres, New Orleans, La., State Analyst, Bureau of Food and Drugs
Margaret C. Moore, 4833 St. Charles Ave., New Orleans, La., Assistant State Chemist, State Board of Health
James E. Thomson, 110 Hudson St., New York, N. Y., Manager, Production and Quality Control, Borden's Farm Products

Industrial Hygiene Section

James P. Deery, M.D., 58 Bainbridge Ave., Providence, R. I., Chief, Division of Industrial Hygiene, State Dept. of Public Health
W. Eugene Masters, M.D., 750 N. High St., Columbus, O., Medical Supervisor, Bureau of Occupational Diseases, State Dept. of Health
Herbert I. Miller, Jr., 2609 Charlock, Overland, Mo., Industrial Hygiene Engineer, State Board of Health
Carl A. Nau, M.D., State Dept. of Health, Austin, Tex., Director, Division of Industrial Hygiene
Frank A. Patty, 80 Maiden Lane, New York, N. Y., Industrial Hygiene Research Worker, Fidelity and Casualty Company of New York
Beverly L. Vosburgh, M.D., General Electric Co., Schenectady, N. Y.

Child Hygiene Section

Orville Barbour, M.D., 528 Jefferson Bldg., Peoria, Ill., formerly Pediatrician, Peoria Public Health Nursing Assn. Clinic
Lloyd A. Masterson, M.D., 313 New Courts Bldg., New Orleans, La., Director, Division of Maternal and Child Health, State Board of Health
M. Alexander Novey, M.D., 2424 Eutaw Place, Baltimore, Md., Chief, Division of Maternity Hygiene, City Health Dept.

Public Health Nursing Section

Alice A. Campbell, R.N., Court House, Lewiston, Ida., Supervising Nurse, Nez Perce County Health Dept.
Mary M. Cosgrove, R.N., 517 S. 4th Ave., Pocatello, Idaho, Staff Nurse, Bannock County Health Unit
Hazel M. Dobson, Box 502, Pocatello, Idaho, Staff Nurse, Bannock County Health Unit
Margaret E. Fuchs, 912X–9th St., Lewiston, Idaho, Hourly Nursing Service, Nez Perce County Health Dept.
Ruth C. Havenor, c/o County Surveyor, Pocatello, Idaho, Nurse, Bannock County Health Unit
Carolyn M. Hidden, 1 Madison Ave., New York, N. Y., Territorial Supervisor, Metropolitan Life Ins. Co.
Nell K. Hulett, R.N., Grace, Idaho, District Nurse, Dept. of Public Welfare

Audrey E. Jones, R.N., 412 Fourth Ave., Lewiston, Ida., Nurse, Nez Perce County Health Unit

Minerva G. Kloster, Riverside Inn, Lava Hot Springs, Idaho, Staff Nurse, Bannock County Health Unit

Margaret Millay, R-2, Box 374A, Lewiston, Idaho, Staff Nurse, Nez Perce County Health Unit

Helen M. Noble, R.N., Rawls Hotel, Enterprise, Ala., Public Health Nurse, Tuberculosis Survey, Alabama and Tennessee

Lillian O'Callaghan, R.N., Court House, Lewiston, Ida., Staff Nurse, Nez Perce County Health Unit

Laura E. Peck, 900 Blaine, Detroit, Mich., Supervisor, Communicable Disease Nursing Division, Dept. of Health

Phyllis Pehrson, 495 E. 1st N., Logan, Utah, Visiting Nurse, Metropolitan Life Ins. Co.

George C. Payne, M.D., Dr.P.H., San Juan, P. R.

UNAFFILIATED

Francis E. Colien, Ph.D., Omaha, Nebr.

CORRECTION

In the August *Journal*, on page 812, appeared a filler on "Causes of Insanity," taken from a magazine which comes to the A.P.H.A., and which was thought to be reliable. However, we find now it was not so, and we can get no definite information on such a study having been made by the American Medical Association.

NEWS FROM THE FIELD

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

THE Association of Women in Public Health will hold its customary dinner meeting on Monday evening, October 20, just before the first session of the American Public Health Association. This is an open meeting which all members of the A.P.H.A. and their friends are invited to attend. The A.W.P.H. meeting is always an informal friendly gathering, one of the prime objects of the Association being the strengthening of old acquaintanceship and the forming of new ties of fellowship. The program, necessarily brief, will consist of several 10 minute discussions of the changes which have come about in various fields of public health during the past year, a sort of parade of New Styles in Public Health.

Dinner will be served promptly at 6:30 at $1.50 per plate. Tickets may be obtained at the main Registration Desk.

WILLIAM HALLOCK PARK LABORATORY

ON Tuesday, October 6, the New York City Department of Health will dedicate a new laboratory building for the laboratory unit at the foot of East Sixteenth Street so long directed by Dr. William H. Park. The dedication will be utilized to pay a tribute to the distinguished services rendered by Dr. Park in the promotion of public health. Hereafter the laboratory will be known as the William Hallock Park Laboratory.

With the dedication of the new laboratory Dr. Park will relinquish active direction, this work being intrusted to Dr. Ralph Muckenfuss. Dr. Park entered the service of the Department of Health in April, 1893, and has thus been in continuous service for over 43 years. Speakers at the dedication exercises will include Surgeon-General Parran, Professor C.-E. A. Winslow, Mayor LaGuardia, Commissioner John L. Rice, and others.

ROAD NAMED FOR HENRY ROSE CARTER

CARTER Place, Balboa Heights, C. Z. South of Gorgas Road, and extending from the Cathedral of St. Luke to Frangipani Street, a palm-lined roadway passes in front of the official quarters of the Superintendent of Gorgas Hospital. On this site

formerly stood the quarters occupied by the late Henry Rose Carter, U. S. Public Health Service, Chief Quarantine Officer of the Isthmian Canal Commission and later Director of Hospitals. Here Dr. Carter lived from June, 1904, until September, 1909. By proclamation, dated July 16, 1936, J. L. Schley, Governor of the Canal Zone, designated the roadway as Carter Place, honoring one of the Service's most beloved and distinguished officers.

In his citation, Governor Schley said, "Dr. Carter was recognized as one of the most efficient and valuable of the Department of Sanitation personnel during the construction period; his work contributed largely to the successful organization of the Department of Sanitation and its hospitals and quarantine service and to the early control of infectious diseases so largely prevalent at the time of the inception of the work."—*Health Officer*, Sept., 1936.

HEALTH COMMITTEE APPOINTED FOR NEW YORK WORLD'S FAIR

THE Advisory Committee on Medicine and Public Health, one of the first of the technical committees of the New York World's Fair, has been appointed. This committee includes 3 members of the American Public Health Association Committee on American Museum of Hygiene. It is expected, therefore, that plans for the health exhibit at the Fair will be correlated with those of our committee for a permanent museum of hygiene in America. Members of the committee are:

Louis I. Dublin, Ph.D.,* *Chairman*
James R. Reuling, Jr., M.D., *Vice-Chairman*
Homer N. Calver,* *Secretary*
John L. Rice, M.D.
S. S. Goldwater, M.D.
George Baehr, M.D.
Victor G. Heiser, M.D.*

* Members of American Public Health Association Committee

As Chairman, Dr. Dublin, who sailed September 5 for Europe, was authorized to extend an invitation to international health and medical agencies to meet in New York at the time of the Fair. The Secretary of the committee, Mr. Calver, has just returned from a study in Germany of health museums and expositions. The study was financed by a grant from the Oberlaender Trust.

A tentative plan of the medical and health exhibits has been prepared. Early this fall a meeting of representatives of all local and national agencies concerned will be held to complete organization and exhibit plans.

NURSES NOTE!

CHANGE of date and program for The Nurses' Session at the National Safety Congress and Exposition to be held in coöperation with the National Organization for Public Health Nursing, at Atlantic City, N. J. Time of Meeting—Wednesday, October 7, 1936, at 9:45 A.M. Topic—Panel Discussion—"Industrial Nursing Pays in Relation to Industrial Health and Safety."

TABULATION OF HEALTH DEPARTMENT SERVICES

REQUESTS are not infrequently received by the Association for advice and assistance in the preparation of forms for tabulating services rendered by health departments. Because of great diversity in procedure, it is gratifying to find published a report of the Committee on Records and Reports of the State and Territorial Health Officers and the U. S. Public Health Service, as published in *Public Health Reports* for September 4, 1936, page 1236.

This committee, reporting in April, 1936, presents a suggested list of items to be tabulated by local health officers, together with covering definitions and

instructions. It is believed that this is the first occasion on which official sanction has been given to report forms and definitions of this kind. It should prove helpful not only to state health departments desiring to conform to the usages of the U. S. Public Health Service and the Children's Bureau, but it should be useful alike to any health department wishing to present its material in an orderly fashion and under definitions which will make the tables more comparable with other agencies than previously has been the case.

BRITISH MEDICAL ASSOCIATION

THE 104th annual meeting of the British Medical Association was held in Oxford, England, July 17–25, under the Presidency of Sir James Barrett, of Melbourne, Australia. Prof. Robert J. Johnstone, Queens University, Belfast, Ireland, was named President-Elect, and Sir E. Farquhar Buzzard, of Oxford, was inducted into the presidency.

MICHIGAN HAS NEW LABORATORY

A NEW laboratory building for the State Department of Health is under construction 4 miles north of Lansing. This is a WPA project. All departments of laboratory work will be carried on in the new structure. C. C. Young, D.P.H.,* Lansing, is in charge of the State Department Laboratory.

NEW WISCONSIN HEALTH UNITS

DR. C. A. HARPER, State Health Officer, Madison, Wis., announces that the state has been divided into 9 district health units, together with 3 county units, of which 1 is actually in operation. These units, which cover the entire state, have been created in coöperation with the U. S. Public Health Service.

Prior to the Social Security Act, there were 5 district health units in Wisconsin. At present each district unit consists of a medical director, a sanitary engineer, a certified public health nurse and an office secretary. The county unit consists of a personnel of 4 and the choice is given to the county whether they desire a sanitary engineer or a sanitarian.

The health officers for the 9 districts and the county units are as follows: (1) Dr. G. W. Henika, Madison; (2) Dr. G. E. Hout, Elkhorn; (3) Dr. V. A. Gudex, Fond du Lac; (4) Dr. E. H. Jorris, Mauston; (5) Dr. L. M. Morse, Neillsville; (6) Dr. Allan Filek, Green Bay; (7) Dr. F. P. Daly, Chippewa Falls; (8) Dr. R. L. Frisbie, Rhinelander; (9) Dr. John W. Lowe, Ashland. County Unit—Dr. Harold W. Fechtner, Wausau.

DRS. PARK AND SENIOR RETIRE

DR. WILLIAM H. PARK,* Hermann N. Biggs Professor of Preventive Medicine, and Dr. Harold Dickinson Senior, Professor of Anatomy, at New York University College of Medicine, retired from the faculty September 1 as professors emeritus. Dr. Park has been connected with the college since 1893, and Dr. Senior since 1910.

ARMY MEDICAL LIBRARY ANNIVERSARY

THERE will be a celebration of the One Hundredth Anniversary of the founding of the Army Medical Library, of Washington, on November 16. The ceremonies will take place in the Library Building.

PERSONALS

DR. ALFRED F. SMITH, of Georgetown, Ky., has been appointed Health Officer of Greenup County, succeeding Carl M. Gambill, M.D.†

DR. JOSEPH J. REPA, of Cresson Pa., has joined the staff of the Alabama

* Fellow A.P.H.A.
† Member A.P.H.A.

State Department of Health as full-time Pediatrician.

DR. HENRY P. WORSTELL, of Columbus, Ohio, has been appointed Orthopedic Consultant to the medical division of the State Industrial Commission.

DR. THOMAS E. MORGAN, Jacksonville, Fla., has been appointed in charge of the newly organized health unit in Pinellas County, with headquarters in Clearwater.

DR. JAMES WILLARD MCMURRAY, Bartow, Fla., has been appointed District Health Officer of West Florida, with headquarters in Marianna.

DR. MARION W. CASKEY,† Taylorville, Ky., has been appointed head of a new health unit at Lewiston, Idaho, one of ten to be established in the state. Dr. Lester C. Krotcher, Coeur d'Alene, has been placed in charge of a unit in Twin Falls, Idaho.

DR. FREDERICK G. NOVY, Dean Emeritus and Professor Emeritus of Bacteriology, University of Michigan School of Medicine, Ann Arbor, received the honorary degree of Doctor of Laws at the 92nd commencement of the University of Michigan. This was the 50th anniversary of Dr. Novy's graduation from the university.

DR. HARRIET BIXBY, Boston, has been appointed state bacteriologist and Dr. August Orr, Sarles, director of the Child Hygiene Division of the North Dakota State Department of Health. Dr. Bixby succeeds A. W. Eckland, Bismarck, resigned. Dr. Orr's appointment marks the reestablishment of the Division of Child Hygiene with Social Security funds, after a lapse of several years.

DR. CYRUS R. WOOD, Port Clinton, Ohio, has been appointed Health Officer of Ottawa County, to succeed the late Dr. Charles B. Finefrock.

DR. HUBERT R. OWENS, Wedowee, Ala., has been appointed Health Officer of Winston County.

DR. FRANK M. HALL, formerly of Leeds, Ala., has been appointed Health Officer of Limestone County.

DR. MARTLE F. PARKER, Boaz, Ala., has been made Health Officer of Monroe County.

DR. ADDIE M. LYON, Frankfort, Ky., has been appointed Health Officer of Lawrence County.

DR. LEE A. DARE, Ashland, Ky., has been appointed Health Officer of Anderson County to succeed the late Dr. Squire R. Boggess,† Lawrenceburg.

DR. WALTER E. MERCER, for 4 years Health Officer of Webberville, Mich., has been placed in charge of the Bureau of Child Health of the Lansing Department of Health.

DR. CECIL C. SMITH, of Indianola, Miss., formerly Director of the Sunflower County Health Department, has been placed in charge of the Pearl River County Health Department, Poplarville.

---

* Fellow A.P.H.A.
† Member A.P.H.A.

DR. HAROLD M. KELSO,† Gallatin, formerly Health Officer of Sumner County, Tenn., is in charge of a new district health unit including the Counties of Fentress, Pickett, Clay, Putnam, and Jackson.

DR. PHILLIP MCGINNES has been appointed Health Officer of Joliet township, Ill., to succeed Dr. Londus Brannon who resigned.

GEORGE F. FORSTER, PH.D.,† Professor of Biology at Olivet College, Olivet, Mich., has been appointed bacteriologist to the State Department of Health. He will be on leave of absence from the college for a year.

COL. HENRY C. PILSBURY,† Medical Corps, U. S. Army, has become Chief Health Officer of the Panama Zone. He will be in charge of sanitation and hospital service, stationed at Balboa.

DR. JOHN W. WILLIAMS, JR.,† Springfield, Mo., Health Officer of Greene County for the past 11 years, has been appointed director of rural health with the State Board of Health under the Social Security Program. Dr. Lynn M. Garner,† Health Officer of Miller County, has succeeded Dr. Williams in Greene County.

DR. CLARENCE E. SHERWOOD, Madison, S. D., has been appointed Health Officer of Lake County, to succeed the late Dr. Emerson W. Goldman.

DR. JOHN W. LOWE,† Merrillan, Wis., has been appointed Health Supervisor of the district including Ashland, Bayfield, Burnett, Douglass, Iron, Sawyer, and Washburn Counties, with headquarters at Ashland.

DR. VAUGHN L. HARTMAN, Medina, Ohio, has been appointed Commissioner of Health of Medina County.

* Fellow A.P.H.A.
† Member A.P.H.A.

C. H. BENNING, M.D., C.P.H.,* recently Deputy Commissioner of Health of Oakland County and Director of Health of the Royal Oak District, Mich., since 1927, has become Director of School Health in Peoria, Ill.

MARGUERITE WALES, R.N.,* has resigned as General Director of the Henry Street Visiting Nurse Service, New York, N. Y., and will join the staff of the W. K. Kellogg Foundation of Battle Creek, Mich., to undertake a study of rural nursing problems in relation to the Foundation's program for the advancement of child health and welfare. Elizabeth J. Mackenzie, formerly Associate Director, will serve as Acting General Director in Miss Wales's place.

DR. WADE WRIGHT

DR. WADE WRIGHT, member A.P.H.A., of Roxbury, Conn., died August 25, after a long illness.

He was with the American Expeditionary Forces overseas and was Deputy Commissioner in charge of the medical relief commission sent by the American Red Cross to the Polish front in the typhus zone.

He became instructor in Industrial Medicine at the Harvard Medical School and was for several years in charge of the Industrial Clinic operated by Harvard as a department for clinical research in occupational disease problems at the Massachusetts General Hospital, Boston.

In 1924, Dr. Wright was appointed Assistant Medical Director of the Metropolitan Life Insurance Company to organize its Industrial Health Service for group policyholders. He retired from the Metropolitan in 1930 because of ill health.

Dr. Wright was Chairman of the Industrial Hygiene Section of the American Public Health Association 1921–1922.

DEATHS

THE death of PROF. JULIUS TANDLER in Moscow, Russia, was announced August 26. Professor Tandler had frequently lectured in the United States and was head of the Russian Health Institute as well as former head of the Vienna University Faculty and Austrian Federal Minister of Health. Dr. Tandler was Commissioner of Health, Hospitals and Public Welfare in Vienna for more than 10 years. During his administration he divided the city into 200 districts, each with a practising nurse, and he was active in the establishment of kindergartens in which care was given to the children of poor parents. Dr. Tandler was also active in the establishment of marriage advice bureaus in Vienna. At one time he was Professor of Anatomy at the University of Vienna and had wide interests in the matter of public hospitals and asylums and in the problem of alcoholism.

FRANKWOOD E. WILLIAMS, M.D., formerly Medical Director of the National Committee of Mental Hygiene, and subsequently in private practice in New York City, died September 24.

DR. FRANK G. ATWOOD,† New Haven, Conn., bacteriologist and veterinarian, died on September 14.

† Member A.P.H.A.

CONFERENCES AND DATES

Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt. Oct. 20–23 (Tues., Wed., Thurs., Fri.).

Associations meeting with the A.P.H.A. —New Orleans, La., Oct. 20–23:
- American Association of School Physicians.
- American Association of State Registration Executives.
- Association of Women in Public Health.
- Conference of State Laboratory Directors (Oct. 19).
- International Society of Medical Officers of Health.
- National Committee of Health Council Executives.
- State Conference of Sanitary Engineers (Oct. 19–21).
- State Registration Executives.

American Association of School Physicians. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

American Association of State Registration Executives. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

American Water Works Association:
- Missouri Valley Section. Iowa City, Ia. Oct. 26–28.
- New Jersey Section—Joint Convention with the New Jersey Association of Water Superintendents. Hotel Ambassador, Atlantic City, N. J. Oct. 23–24.
- New York Section. Saratoga Springs, N. Y. Oct. 15, 16.
- Southwest Section. Hotel Goldman, Fort Smith, Ark. Oct. 12–15.

Army Medical Library. Celebration of the One Hundredth Anniversary of the Founding. Library Building, Washington, D. C. Nov. 16.

Association of Military Surgeons. Detroit, Mich. Oct. 29–31.

Association of Women in Public Health. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

Canadian Dental Association. Montreal, Que. Oct. 12–13.

Civil Service Assembly of the United States and Canada. Cincinnati, Ohio. Oct. 21–24.

(*Conferences continued on page 1070*)

Conference of State Laboratory Directors. Hotel Roosevelt, New Orleans, La. Oct. 19.

Conference of State Sanitary Engineers. New Orleans, La. Oct. 19–21.

Dairy Industries Exposition. Atlantic City, N. J. Oct. 12–17.

Dairy Show, Centennial Exposition. Atlantic City, N. J. Oct. 17–25.

Fire Prevention Week. Oct. 6–12.

International City Managers' Association. Richmond, Va. Oct. 19–21.

International Society of Medical Officers of Health. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

Interstate Commission on the Delaware River Basin—Public Meeting, on Water Supply, Flood Control, and Pollution. Buckwood Inn, Shawnee-on-the-Delaware, Pa. Oct. 2–3.

Malaria, Third International Congress on. Madrid, Spain. Oct. 12–18. *Adjourned because of unrest in Spain.*

Missouri Public Health Association. Columbia, Mo. Oct. 1–3.

National Association of Exterminators and Fumigators. Cleveland, Ohio. Oct. 26–28.

National Committee of Health Council Executives. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

National Dairy Show, National Dairy Association. Dallas, Tex. Oct. 10–18.

National Rehabilitation Association. San Antonio, Tex. Oct. 26–30.

National Safety Council—Annual Safety Congress and Exposition. Atlantic City, N. J. Oct. 5–9.

New Jersey Association of Water Superintendents — Joint Convention with the New Jersey Section, American Water Works Association. Hotel Ambassador, Atlantic City, N. J. Oct. 23–24.

New Jersey Health and Sanitary Association, Inc.—Sixty-second Annual Meeting. Hotel Woodrow Wilson, New Brunswick, N. J. Nov. 20–21.

New York State Association of Public Health Laboratories. New York State Laboratory. Albany, N. Y., Nov. 6.

New York State Sewage Works Association. Geneva, N. Y. Oct. 9–10.

Ontario Hospital Association. Toronto, Ont. Oct. 21–23.

Pennsylvania Water Works Association. Haddon Hall, Atlantic City, N. J. Oct. 14–16.

Public Ownership League of America. Abraham Lincoln Hotel. Springfield, Ill. Oct. 15–17.

Southern Tuberculosis Conference. Hot Springs, Ark. Oct. 1–3.

State Conference of Sanitary Engineers. Hotel Roosevelt, New Orleans, La. Oct. 19–21.

State Laboratory Directors, Conference of. Hotel Roosevelt, New Orleans, La. Oct. 20–23.

Texas Public Health Association. Kilgore Hotel, Kilgore, Tex. Oct. 14–16.

Third International Congress on Malaria. Madrid, Spain. Oct. 12–18. *Adjourned because of unrest in Spain.*

Water Supply, Flood Control, and Pollution—Public Meeting of the Interstate Commission on the Delaware River Basin. Buckwood Inn, Shawnee-on-the-Delaware, Pa. Oct. 2, 3.

West Virginia Public Health Association. Wheeling, W. Va. Oct. 12–14.

To Members of
American Public Health Association

Gentlemen:

We extend to you a cordial invitation to visit our exhibit at the meeting of the American Public Health Association, to be held in New Orleans October 19th to 22nd -- Booth 17.

We will present a scientific exhibit showing methods for determining the influence on irritation resulting from cigarette smoking when

A -- Diethylene glycol

B -- Glycerine

are used as hygroscopic agents.

The subject is of medical interest, especially where congestion of some portion of the upper respiratory tract associated with smoking is involved.

Cordially yours,

O. H. Chalkley

President

Positions Wanted

HEALTH OFFICERS

Physician, M.D. Medical College of Virginia; 3 years' in the Medical Corps, U. S. Navy; city health officer for 16 years; desires position as health officer. Eastern city preferred. A-274

Physician, M.D. Hahnemann Medical College; special course in public health at University of North Carolina; wishes position as county health officer in the Northeastern area. Served as school physician of a small township for 7 years. Available at once. A-275

Physician, M.D. University of Wisconsin; M.P.H. Harvard School of Public Health; special courses in industrial hygiene; available now for an administrative position or one in industrial hygiene. A-279

Physician, M.D. New York Medical College and Flower Hospital; extension course for public health officer, New York State Department of Health; 3 years' urologic service in various New York City hospitals; desires position as health officer or in social hygiene department. A-266

Physician, M.D. University of Nebraska; 13 years' experience as city or county health officer in different sections of the West; desires position as health officer. Prefers West Coast. A-267

Physician, M.D. Indiana University; C.P.H. Johns Hopkins University; special courses in epidemiology, bio-statistics and public health administration; several years' experience as physician to city health department; desires position as full-time county health officer. A-269

Physician, M.D. Western Reserve University; 3 months' Health Officers' course at Johns Hopkins; 1 year's experience as instructor of Hygiene and Bacteriology; 4 months as county health officer; desires position as health officer or in the field of research. A-273

LABORATORY

Young man, M.S. in Bacteriology, University of Colorado, desires position in a health department laboratory or in the teaching field. Experience covers laboratory work in a state health department, graduate assistant in the department of bacteriology and public health of a university school of medicine, and bacteriologist and chemist of a city health department. West preferred. L-276

Young woman, B.S. University of Chicago, desires position in the field of bacteriology or parasitology. Has been employed as first assistant and research fellow in the department of bacteriology, parasitology and serology of a Chicago hospital, head of a private clinical laboratory, supervisor of a unit for survey of food handlers for carriers of E. Histolytica under Chicago Board of Health, bacteriologist in a health department and in a tuberculosis sanitarium. L-277

Laboratory man available. Trained at New York Post-Graduate and at St. Luke's, New York, in bacteriology, serology, hematology, blood chemistry and urinalysis; 13 years' experience in all routine procedures except tissue. L-278

Young woman, B.S. Tufts College; M.S. University of Illinois; Ph.D. Western Reserve University; 4 years' experience as director of a city health department laboratory and several years' experience in both commercial and hospital laboratories; desires position doing research or routine in chemistry, biochemistry, bacteriology or serology in public health laboratory. L-272

Technician, young man, graduate Brooklyn College; extensive experience in laboratory medicine, blood chemistry, bacteriology; several publications in serology; former research worker in Grade A medical school; special work in Darkfields; desires position as medical technician or research worker. L-218

MISCELLANEOUS

Physician, graduate of Washington University Medical School, desires position with state department of public health to do educational writing on mental hygiene, child guidance or venereal diseases. Capable of group instruction in health education. M-197

Young woman, Ph.D. Columbia University; considerable experience in the field of health education with official, voluntary and commercial organizations; is interested in a position as Director of Public Health Education in a city, state or agency. M-255

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

VITAMINS IN CANNED FOODS

IV. VITAMIN B_1

The story of vitamin B_1 is quite long and involved. Properly, it has been fully covered at some length in authoritative dissertations on the vitamins (1).

The original vitamin B of Eijkman and of Funk, while definitely possessed of antineuritic potency, is now known to be of a complex nature. Between 1919 and 1926, the vitamin B complex was resolved into vitamins B (B_1) and G (B_2). Subsequent work has indicated the existence of other vitamins in the complex, whose chemical natures or relations to human nutrition are not as yet clearly understood.

As a direct result of many researches on vitamin concentrates, the chemical identity of the crystalline antineuritic factor has recently been described as a derivative of 6-aminopyrimidine (2).

It has been known for many years that vitamin B_1 may be destroyed by heat. In the canning procedure, a number of heat treatments of food may be involved, especially in the thermal "processing" of the product to insure its preservation. In the "process", many foods are subjected to a heat treatment after sealing in the can, to destroy spoilage organisms which may be present on the raw material. In other cases, the food is filled into the cans at a sufficiently high temperature to obtain the same result. Therefore, the question of the effect of the canning procedures on vitamin B_1 frequently arises.

The times and temperatures necessary for the processing of canned foods are governed by a number of factors, important among them being the pH of the food itself. Highly acid foods require only short heat processes at the temperature of hot or boiling water to destroy spoilage organisms. The so-called "non-acid" or "semi-acid" products require higher temperatures —usually 240°F. (116°C.).

As might be expected, acid foods have been found to suffer only a slight loss of vitamin B during canning (3).

The degree of retention of vitamin B_1 in the non-acid foods is not as high as in the acid foods. (4).

This is partly due to the heat treatments accorded them and possibly also to their low acidity, since the vitamin is more stable in acid media.

The facts in the case may be summarized briefly by the statement that commercially canned foods may be depended upon to supply vitamin B to extents consistent with the amounts of the vitamin originally present in the raw materials from which they were prepared. Because of their widespread use, canned foods contribute a notable amount of vitamin B_1 to the American dietary.

AMERICAN CAN COMPANY

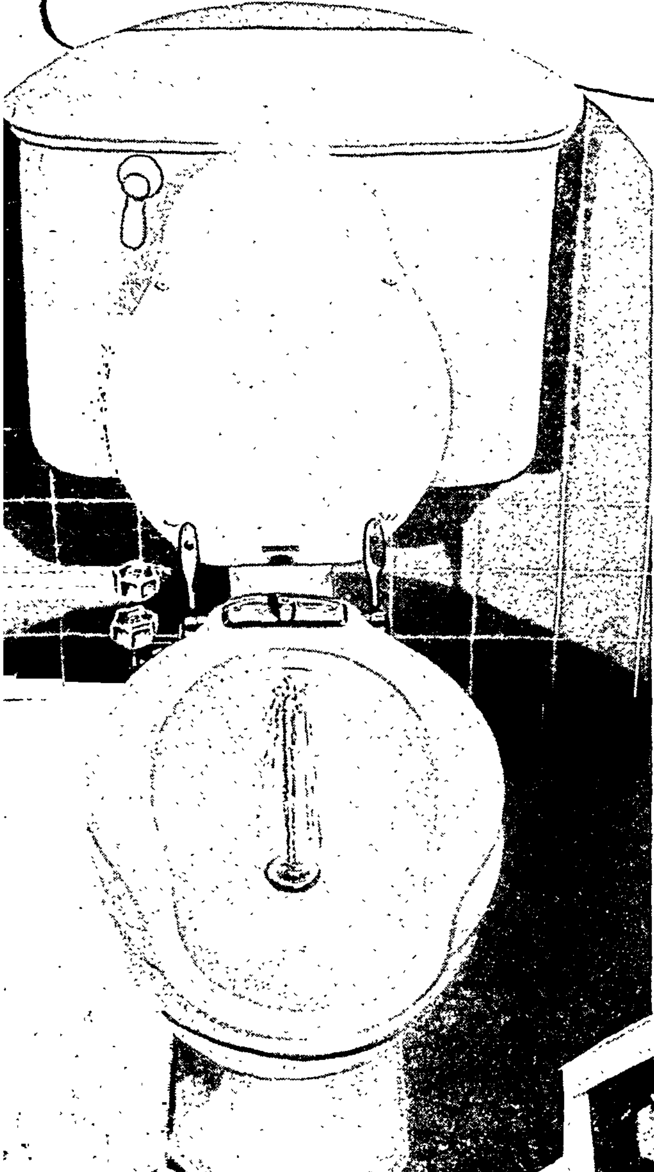
Safeguarding Public Health is a SACRED Trust



The Nu-Bidet is a complete unit of seat, Nu-Bidet and lid in one assembly, which replaces the regular seat and lid. *It is equipped with a specially designed and patented vacuum breaker and also a specially designed venturi siphon breaker, making back siphonage or a cross connection impossible.*

BY BETTY LOU WILLIAMSON, R.N.

The more that the public becomes hygiene minded; the more they know about keeping clean—just plain downright cleanliness—the better citizens they become.

They *think better and bigger thoughts;* they work better and they accomplish greater results. They become open-minded and receptive to higher standards of living and they make greater progress.

The Nu-Bidet is a definite and forward step in that direc*tion. Its use is a liberal education in personal cleanliness,* self-respect and higher ideals.

If you but realize it, the Nu-Bidet is as necessary to personal hygiene and general cleanliness, in every home, hospital and public institution, as a bathroom or a tooth brush.

The Nu-Bidet *is a most advanced step in the* safeguarding of public health. *You owe it to yourself and the position you* hold to know all about it. Use the coupon now.

WHAT IS THIS NU-BIDET? READ THIS!

The Nu-Bidet is a thoroughly modernized Sitz Bath...and more. The following uses make it a safeguard to health and as necessary to personal hygiene as your tooth brush or the bathroom itself.

Sitz Bath for personal hygiene and treatment of rectal disorders. Spray for same purpose and feminine hygiene. Attachment for douche, enema and hydrotherapeutics, entirely eliminating the old rubber bag method.

The Nu-Bidet can be installed on any standard size toilet bowl in less than two hours. It will convert the ordinary bathroom into one that is truly hygienic at a small investment. Use coupon now.

We can now make Immediate Deliveries

The Nu-Bidet lifts up and stands against the lid when not in use.

The Nu-Bidet looks like the average toilet. No extra space required.

The Nu-Bidet

How long should a Man's legs be?

Lincoln had a good answer. "Long enough," he drawled, "to reach from his body to the ground."

THAT seems like a good rule to apply to a business. It ought to be big enough to do the job it is intended to do.

Have you ever thought about the size of a company—what makes it big or small?

It isn't the directors and it isn't the stockholders — but the public. No business grows, and keeps on growing, unless it meets the people's needs and renders a worth-while service at a fair price.

The Bell System has developed along those lines for over fifty years. It has grown as the nation has grown. It has to be big to provide efficient, adequate telephone service to 127,000,000 people.

BELL TELEPHONE SYSTEM

Color reprint suitable for framing will be sent to physicians and public health officers on request.

IT IS our privilege to present, as our contribution to public health education in America, the Camp Transparent Woman—an exact life-size reproduction of the female body, with every organ, blood-vessel and bone clearly visible. Before going on a transcontinental tour, this figure is being shown to the general public at the New York Museum of Science and Industry, where leading medical and health authorities attended its recent premiere.

It is our earnest hope that the Camp Transparent Woman will increase woman's knowledge of her physical self and foster a more enlightened attitude toward the advice of the physician.

INDEX TO ADVERTISERS

Control of Type I and Type II Pneumonias with

ANTIPNEUMOCOCCIC SERA

Lederle

SUCCESS IN THE SERUM TREATMENT of lobar pneumonias is measured by . . .

- a 60% reduction in the death rate of Type I cases
- a 40% reduction in the death rate of Type II cases
  (if injected within 96 hours of onset)

Specific antipneumococcic sera offer the only certain means of reducing the death rate in Types I and II pneumococcus pneumonias — the cause of nearly 50% of all adult lobar pneumonias between the ages of five and fifty.

> "The Massachusetts Pneumonia Study, under the auspices of the State Department of Health, has demonstrated that specific treatment can be successfully used by physicians in general practice. Over nine hundred patients with lobar pneumonia have been treated by nearly four hundred physicians."*

Success is largely dependent upon prompt bacteriological diagnosis facilitated by the Neufeld Rapid Typing; early and adequate treatment; and of equal importance—the use of serum of the highest quality.

Refined and Concentrated Antipneumococcic Serum *Lederle* represents the accrued knowledge gained by years of experience in its manufacture.

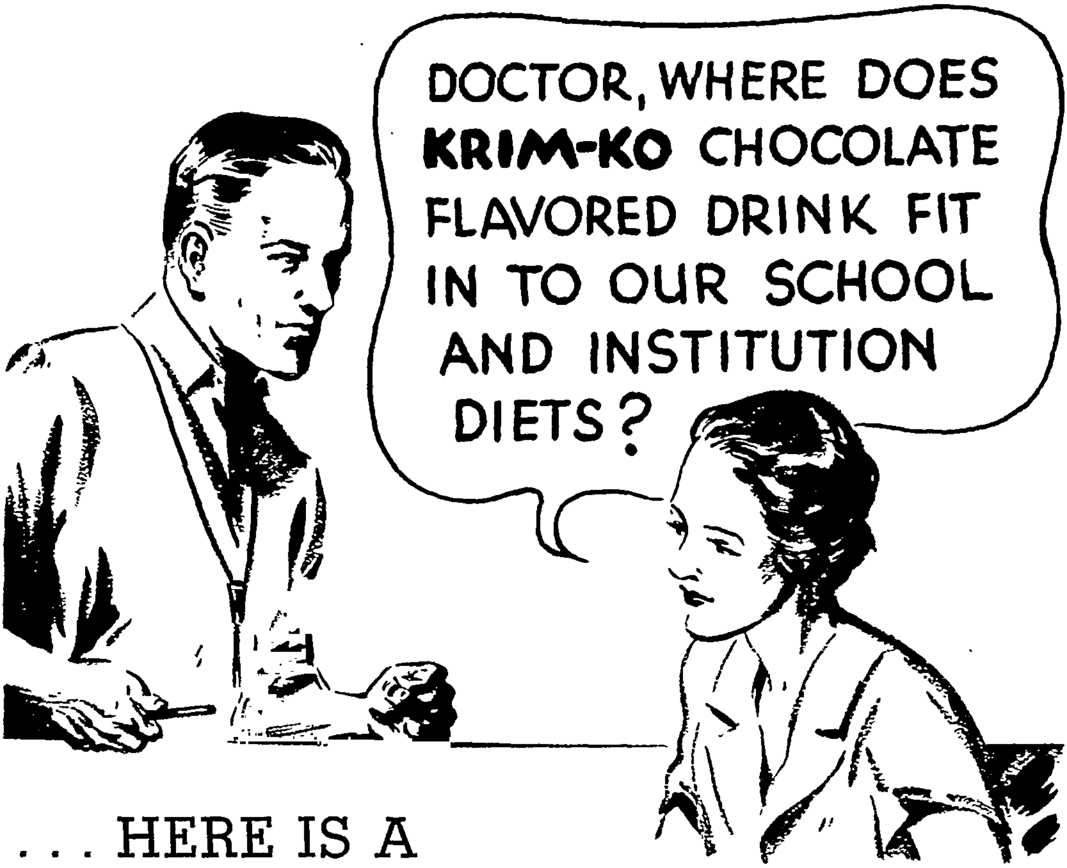
MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858



. . . HERE IS A FRANK ANSWER!

Krim-Ko is not intended to replace milk in the normal diet—altho an occasional serving of Krim-Ko with its likable chocolate flavor does help prevent taste monotony.

But there is a large number of children and adults, who drink no milk at all because of taste prejudice. This group will drink Krim-Ko, which gives them some butter-fat and all the Calcium and Phosphorus found below the *cream line in milk.*

The important food value of milk is below the cream line because milk is one of the best food sources for Calcium—and Calcium is probably the greatest single deficiency in the American diet.

Krim-Ko, rich in Calcium, equal to milk in food energy value, is bottled and pasteurized by selected local dairies. It carries the Seal of Acceptance of the Council on Foods of the American Medical Association.

FREE DIET INFORMATION

Everyone concerned with health and food should have the story of the valuable elements found in Krim-Ko Chocolate Flavored Drink. We shall be glad to furnish you complete information about Krim-Ko and its place in the diet—Write today to the Krim-Ko Company, 4830 S. Turner Ave., Chicago, Ill.

KRIM-KO

REG. U.S. PAT. OFF

Krim-ko is chocolate flavored, pasteurized, partially de-fatted milk (added Tapioca-salt)

Reporting Progress*

THOMAS PARRAN, M.D., F.A.P.H.A. (*Life Member*)

President of the American Public Health Association; and Surgeon General, U. S. Public Health Service, Washington, D. C.

IT is a signal honor for any member of our profession to be elected to the presidency of this Association. I am deeply grateful for the esteem and confidence of my colleagues who have given me this high office of privilege and opportunity.

We are met in this 65th Annual Convention as an organization invested with new life, a new interest in the contemporary scene, and a new zest for the tasks before us. Because social concepts are changing, and among them the concept of public health, the wisdom we show in dealing with those tasks will determine largely the future of public health in our time. And what wisdom we have had, for the most part has stemmed directly from our professional collaboration in this, the only professional organization in which there is a place for all public health workers.

Our common interests grow with the expansion of our work, and the needs of the Association keep pace with them. Just as laboratory equipment needs to be kept up to date, so the Association from time to time will need to adjust and readjust details in plan and program to promote the continuing purpose of the Association, which is the attainment for public health of its rightful place in the life of the nation. This purpose is so fundamentally important that its achievement should command the personal service, the active interest, and the zealous loyalty of each member of our profession. Our membership should be doubled, yes even tripled; regional and state societies, now tottering infants, should become powerful branches. For unless the practitioners of public health can make common cause, they will not be able to ask coöperation for their cause from the American people. Drawing its members from many basic sciences, this organization should develop in them the guild spirit. Out of conference, discussion, and study should flow clear statements of policy, objectives, and methods. Public health needs should be interpreted to the people. Appropriate public action to meet those needs should be suggested and encouraged by this Association. Ours is a dynamic profession. In it and because of it great events are transpiring. We have it in our power,

* Presidential Address delivered before the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

through the efficient functioning of this Association, to make permanent contributions to the promotion of physical and mental health for all the people.

What is the place of public health in modern life? Formerly it was concerned only with the mass problems of sanitation. The practical disappearance of many diseases directly caused by an unhealthful environment is one of the brightest chapters in the story of man's progress. But even though such diseases as smallpox or typhoid no longer overwhelm us, we dare not relax our effort. We must hold the lines, consolidate our gains, and push on to the gaining of new ground against the diseases and conditions which continue, needlessly, to waste the lives of our people. Public health in the light of present scientific knowledge goes far beyond environmental sanitation. It necessarily must be concerned with all factors which make for healthful living—the prevention, alleviation, and cure of disease by all methods known to science; the promotion of the physical and mental status of the race; the provision of decent housing, healthful working conditions, facilities for recreation, food adequate in amount and kind for proper nutrition; a standard of living compatible with normal family life and the upbringing of children. It is the *specific* responsibility of public health to provide, through community effort, those services for the saving of life and prevention of disease which the individual is unable to provide, or to provide as well, by his individual efforts.

In addition to those generally accepted health measures which are provided directly by a health department, community effort concerned directly and indirectly with public health may be considered broadly in two groups:

1. Those measures of direct concern to a health department but not necessarily provided by it, such as bedside nursing, medical, dental, and hospital services for the population groups in need of them.

2. General health measures, such as better housing and recreation facilities, which have a direct influence upon health but in this country have been unrelated to health agencies.

There is much difference of opinion as to how far a health department itself should administer activities in the first group.

If control of a disease is possible only when adequate treatment is provided for that disease, it is generally agreed that the health department has a direct responsibility to see that such treatment is given to those unable to provide it for themselves, whether for tuberculosis, for syphilis, or for pneumonia. Such service must be provided and coördinated with other public efforts for the prevention and cure of disease.

In principle, I hold the view that all community services for the prevention of disease and care of the sick should be the responsibility of the health department, in so far as such measures are paid for from public funds. The extent to which these services are actually administered by the health department, however, is a matter which can best be decided by the individual state or locality.

In addition, health departments should be particularly interested in the control of any disease which is a burden to the community, whether or not communicable, because of its wide prevalence or the excessive cost of treatment to the individual. The coordinated campaign against pneumonia launched last year by the organized medical profession of New York State and the State Department of Health is a case in point. Another example is the cancer campaign in Massachusetts. Mass attack upon these and similar diseases is relatively new, however, in a majority of the states. We have been looking at them through a micro-

scope for so long that it is difficult to refocus for a telescopic view. Yet both views are necessary if we are to see them in their entirety, and both the individual and the mass attacks are necessary, if we are to gain ground against our modern plagues.

In the tremendous problem of providing medical care for the indigent, the social welfare agencies have taken the lead, largely because health departments have been unwilling or unable to accept this as a direct responsibility. The situation, however, is somewhat analogous to the relation of the health officer to the public water supply. He must know the needs for an adequate supply of potable water. He champions the provision of such a supply. He sees to it that the water plant is properly operated, even though this may be done by another branch of the city government. This is the minimum responsibility which the health department should assume, both for the public water supply and for the public medical service needed by those unable otherwise to provide it. In fact, the health department should be instigator of and friend to all useful activities for the conservation of life and health. For if health officers do not recognize their responsibility, using all methods given us by science, to organize community attacks upon causes of ill health, the public health profession will revert to the ancient status of sanitary police, and other public medical agencies will be established to deal with the major health problems of today and tomorrow. We may be sure such problems will be dealt with.

Chief among the problems of today is that of establishing upon sound bases the health provisions of the Social Security Act. Last year in Milwaukee we heard several discussions of the promise to health work inherent in this Act. This year we can report that this promise is being realized in terms of more and better health service to the people. Though relatively small in total expenditure as compared to that for other aspects of security, the $13,200,000 allotted this year from the Public Health Service and the Children's Bureau, as compared with the previous meager and sporadic federal appropriations, represents a great advance and has helped to provide more tools for life saving. It has lessened by a little the gap between our knowledge and our performance of how to promote health. It has given us, at last, the beginnings of a national health program. Though we are spending for this purpose about 10.7 cents per capita, or about 10 per cent of previous public health expenditures, nevertheless these funds have made it possible to employ 2,536 full-time persons and 496 part-time personnel, among whom are 579 physicians, 1,081 nurses, 65 dentists, 144 engineers, 296 sanitary inspectors, and 174 laboratory technicians, as well as badly needed clerical assistance.

The administrative organization has been strengthened in all states but 5; $500,000 being spent for this purpose. Local health service is being aided in all states but 2; $3,500,000 being spent for this purpose.

The technical services of the states are using another $1,300,000. Approximately $1,000,000 is being used for the training of 1,243 personnel. Another $1,200,000 is accounted for by special health activities such as work in industrial hygiene, malaria in the southern states, plague on the Pacific Coast, and syphilis wherever the state health authorities have the interest and the energy to pursue it.

In order to match federal health funds, new state and local appropriations approximate $3,000,000.

Further impetus to public health has been given through the use of federal emergency funds which financed the

national health inventory started in 1935 by the Public Health Service and almost completed. This should make available information concerning many aspects of national health heretofore unknown, including the incidence and duration of serious disabling illness among 3½ million persons over a 12 month period; the medical and nursing service which they received; the prevalence of chronic diseases, of orthopedic defects and blindness; the incidence of specific communicable diseases and the completeness of reporting; and the extent and utilization of medical and public health facilities in the different types of communities.

Employment through federal emergency funds has been provided also for approximately 6,000 nurses, themselves destitute, who have been added to the staffs of state and local health departments for community nursing. In some states, this has represented a 50 per cent increase in the total public health nursing personnel. Fifty thousand hospital beds similarly have been provided with the assistance of federal funds.

Community sanitation has been improved in 41 states; approximately 1,000,000 sanitary privies have been constructed. Extensive drainage projects in 16 southern states have provided more than 10,000,000 feet of ditches draining 87,000 acres and protecting 2,290,000 people against malaria. There are under way or completed 4,080 projects for the extension and improvement of public water supplies and sewage disposal plants at a cost to the federal government of $426,572,411. In fact, sewage treatment facilities have been increased by more than 30 per cent during the past 4 years. Pollution of streams has been further reduced by the sealing of nearly 4,000 abandoned coal mines.

In addition to grants-in-aid to states and the use of emergency funds for purposes of health and sanitation, appropriations of the Public Health Service for research into problems of disease and sanitation have been increased by more than $1,000,000. The record will show that the composite of these activities is contributing substantially to the health of the nation. We have made a good start. How far we go depends upon our ability as health workers to get together and to work together, and upon the capacity of the public health profession to interpret such work to the citizen and taxpayer.

This last possibility begins to look somewhat more promising. In the past we have thought somewhat wistfully that public health might be sold to the public if we could train health officers to be orators and advertising writers. That method is as impractical now as it ever was. Yet so far as gaining our objectives is concerned, we are fortunate in that sales resistance is decreasing. It is becoming obvious that the taxpayer can save money through the prevention of disease. He is begining to ask: "Why should we pay pensions for the blind and do so little to prevent blindness? Why should we add to the burden of those made destitute in their old age by chronic preventable sickness? Why should we pay widows' pensions when we could prevent the death of the breadwinner?" There has been added, therefore, to the humanitarian appeal of public health—and humanitarianism is one of the last of the acquired human characteristics—the direct economic advantage of public health work which can be made obvious to the most penny-pinching taxpayer.

The point is that in public health we have a task which, within scientific boundaries, we know how to do. No matter what their school or party, economists have not yet demonstrated that they know how to prevent cycles of unemployment; therefore, insurance

is provided in most civilized nations to soften the impact of a job loss. Until science shows us how to prevent unemployment, we must care for the unemployed. The cost of this, by whatever method, is a necessary tax. Not so the tax for carrying the burden of the needlessly unfit. The mother who dies in childbirth, needlessly; the father who contracts tuberculosis in industry; the young people who are infected with syphilis; the children who grow up deformed by rickets—each contributes to the breaking up of a family, to social and economic loss. All are examples of the *preventive* possibilities of public health provisions under the Social Security Act as contrasted to the *palliative* nature of job insurance and pensions for the unemployable.

We may have confidence not only in objectives of today's national health program, but also in its method. The federal-states relationship in public health functions smoothly because we merely are extending a well established procedure. In 1880 the Congress authorized the Public Health Service to coöperate with states in the prevention and control of epidemic diseases. The mechanism of such coöperation has been worked out during these past 56 years. We can cite this half century of federal-states relationships in public health in support of the soundness of the principle, in the flexibility of action which is permitted, and in the avoidance of over-centralization.

Thus far, I have discussed public action in the health field. A distinctive feature of public health work in this country has been the active participation of voluntary organizations and foundations. The question frequently brought up now is the extent to which the work of such non-governmental agencies will be replaced by the present larger public expenditures.

It is hoped that it never will be necessary to replace the health work of the voluntary organization. Current public expenditures fall far short of present needs. The acceptance by the public of responsibility for work originally started as a voluntary experiment frees voluntary funds for other pioneering effort. The frontier of public health constantly is expanding as science gives us new tools with which to attack new disease problems. The frontier represented by the periphery of a circle obviously grows larger as the circle expands. Moreover, the application of knowledge brings increasingly the need for practical information concerning most effective methods. To develop these methods, to work out new technics, to promote further research, to make experimental application of laboratory facts, to prepare the public mind for acceptance of new health activities, to inform the public of the values and results of public health programs, is the continuing opportunity and obligation of the voluntary and philanthropic health agency.

I have referred to the need for wisdom in doing our tasks. The current extension of public health work makes it extremely important that we should consider critically the work we are doing, appraise the effectiveness of procedures, discard the less useful, and take up with more vigor those tasks which promise a larger return for money and effort. Such studies of administrative practice as have been carried out by this Association, and also studies of public health methods which have been conducted by the Public Health Service are providing tentative means for such appraisal.

Sometimes it has been said that we have been too much concerned with the internal organization of health service and too little concerned with the actual service rendered to the people. The public is interested in what it gets from its health department, not in its form of organiza-

tion. Perhaps we have gone too far also in insistence upon a "balanced program" which, upon analysis, may mean mediocre performance in many fields in accordance with predetermined standards which have little or no scientific basis, rather than a determined and adequate frontal attack on the few major preventable conditions.

An evil to be guarded against in the federal-states relationships and in the work of this Association is too early and too great an insistence upon standardization. The problems of this country are so diverse that we should not make a uniform approach to such a multiform situation. Suppose the automobile manufacturers had standardized on the 1920 models! I fear that some health departments standardized before they modernized.

I agree with those who feel that we should direct our attention to particular diseases and conditions, using the health organization as a means to an end rather than an end in itself. On other occasions I have discussed the reasons why the control of syphilis, tuberculosis, cancer, pneumonia, infant mortality, and improved nutrition should be major objectives. Mental hygiene has a real contribution to make to clear thinking and emotional stability. In certain places it may be malaria or some other geographically limited disease. In every case, however, we should attack with most vigor where the greatest saving of life can be made.

The late Edgar Sydenstricker more than any other individual was responsible for the inclusion of public health in the national program of social security. He has said:

> The program of public health in its broad as well as its narrower sense should be designed to meet the peculiar needs of the individual community rather than to conform to any standard pattern.—The practical coordination of efforts does not necessarily imply public control of such efforts nor the centralization of control or administration. On the contrary, it is assumed that different communities or the individuals composing such communities may discharge its responsibility each in its own way or ways.

I have said that our social concepts are changing, and among them the concept of public health. I believe that among the changes of most significance are first, that citizens are beginning to realize that an effective nation-wide program of public health with federal support is a major factor in any national effort toward economic and social security, toward individual personal security, and toward the security of our major political and social institutions; for it prevents rather than alleviates much disability, dependency, and insecurity.

Second, and closely related, is the dawning of the idea among the public at large that it is financially important to prevent disease.

And finally, there is this great change in our own concept of our profession: Bankers may be at odds about how or when to stabilize our currency. Our greatest lawyers may disagree in fives and fours about the interpretation of the Constitution. Economists and industrialists may wrangle about the balancing of demand and production and the methods of preventing periodic unemployment. We have no part in their quarrels. *This one thing we do!* We are united in the objectives of our campaign against death and disease. We are sure of its place and importance in the growth of our nation. It is my firm belief, and yours, and by the straightforward doing of our task it can become the belief of the nation, that public health must be supported because of its *human* significance.

As President of the American Public Health Association during the coming year, it shall be my one thought that the Association may be serviceable to our purpose.

Importance of the Supervisor in the Industrial Health Program*

LEVERETT D. BRISTOL, M.D., DR.P.H., F.A.P.H.A.

Health Director, American Telephone and Telegraph Company, New York, N. Y.

MUCH of the time and interest of the Industrial Hygiene Section of the American Public Health Association naturally has been given to the scientific, technical aspects of the causes and methods of control of specific occupational diseases. In the valuable discussions of such important subjects as silicosis, lead poisoning, the hazards of various other physical and chemical agents, to say nothing of such diseases as the common cold, pneumonia, and tuberculosis, and the mounting list of off-duty accidents, the important phases of industrial health administration and supervision should not be forgotten. Industrial hygiene cannot be advanced and occupational diseases and accidents cannot be controlled without an adequate set-up, both as regards program and personnel in each industrial organization.

The writer [1] has called attention at various times to the need for development of a well rounded industrial health program in each industry. At this time it would seem desirable to emphasize that one of the additional, outstanding needs in the administration or further extension of a health service, at least in the larger industrial concerns, is the setting up within the company of a completely organized personnel, and delegating the responsibility for such work. In many instances this will necessitate only the filling of certain supervisory "gaps" that exist at present. In other words, the personnel for a health service must be just as well organized in an industry as is the staff for any of the strictly operating activities, even though some of the same individuals may serve both purposes. At the same time, advisory services on health must be provided by special staff personnel, medical or otherwise, to assist the supervisors in the line organization, just as such services are available for technical engineering, manufacturing and operative problems.

In the organization of personnel for industrial health service, it is assumed that: (1) the larger the company the more specialization is possible and the greater is the necessity and opportunity for the division of positions and functions; and that (2) the smaller the company the more generalization is required and the greater is the necessity for the unification of positions and functions, and the need for possible assistance in industrial health work from local health departments or associations. The development of a practical and comprehensive program for health supervision of employees of smaller business concerns probably is

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

the greatest unmet need in the whole realm of industrial health administration.

HEALTH RESPONSIBILITIES OF SUPERVISORS

The key person in the industrial health program should be the foreman or supervisor, just as the key person in the school health program is the classroom teacher. The ultimate responsibility for the health supervision of individual employees among general manufacturing and operating forces will rest with the supervisors, such as supervising foremen and foremen, chief clerks, local managers, chief operators, and other group leaders. Frequent personal contacts between a company medical department and individual workers are impracticable and often impossible. First line supervisors, however, have the opportunity to observe possible day-to-day changes in a fellow worker's physical appearance or mental attitude. The majority of supervisors are definitely interested in the welfare of their workers; it is not difficult, therefore, to get them to see that the health of their subordinates is a part of their job. The problem becomes one of developing effective supervisory methods for promoting health among employees.

The following suggestions cover the possible opportunities and responsibilities of supervisors in industry as regards the health problems of their fellow employees:

A. *To Stimulate the Ideals of Good Health*—Supervisors are acknowledged leaders. This is particularly true as regards the example set through their own conduct and attitude toward health, and in maintaining as healthy an environment as possible.

1. Their own habits of living, including recreational and outside activities, should be such as to stimulate ideals of health among their forces.

2. They should coöperate with the management in its effort to maintain such conditions as proper ventilation, heating, sanitary quarters, and hazard-free methods and equipment.

3. Their interest in company health activities should be active and genuine.

4. Their attitude toward frequent and unnecessary incidental absence on account of personal illness should be constructive and exemplified by their own good conduct in this respect.

5. In personally availing themselves of medical services provided by the company, through the regular lines of organization, they should help to build up confidence in such services.

6. They should refrain, at all times, from diagnosis or prognosis and should create on the part of their people a desire to seek proper medical advice when symptoms indicate the need of such. The confidences of individual employees should be carefully safeguarded.

B. *To Detect Indications of Potential Ill Health Among Employees*—

1. Evidences of minor ailments or warning signals such as continued colds, coughing, sneezing, headaches, indigestion, toothaches, inability to maintain a good posture, skin eruptions, abnormal skin color, noticeable loss of weight, shortness of breath, chronic fatigue, and any other conditions which obviously point to a " below par " or recently changed condition should be noted by the supervisor.

2. Poor quality of work, unsatisfactory mental attitude, friction with other employees, particularly supervisory people, which cannot be traced to the commonplace events of everyday working conditions, may indicate severe mental or nervous strain due to a multiplicity of causes which should be investigated.

3. Frequent absences from work reported as due to incidental ill health; repeated use of rest rooms; and

irritation at or inability to tolerate comfortably adequate and reasonable ventilation and proper heating arrangements should be recorded.

C. *To Take Proper Action With Regard to Unsatisfactory Conditions*—

1. Supervisors should advise employees to seek proper medical and dental attention for correction of minor defects.

2. Consultation and coöperation with available medical and dental advisers in individual cases should be arranged.

3. After determination has been made of the causes of repeated incidental absences, and the causes of poor mental attitude, preventive measures should be adopted.

4. Emergency action should be taken with reference to employees exposed to or exhibiting apparent symptoms of either occupational or communicable disease until the facts can be secured.

5. Observation of employee's attitude and appearance for some time after return to work following absence due to sickness should be a part of the supervisor's routine. The supervisor's interest and responsibility should be continuous and should not end when a worker has been referred to a physician or the company medical department.

HEALTH TRAINING OF SUPERVISORS

Modern industry requires that the supervisor must have a fairly complete understanding of the physical and mental needs of the individual workers under his charge, in addition to having a thorough knowledge of the job itself and of its possible disease or accident hazards. Thus, the subject of health must have a prominent place in any present or future program of supervisory training, and before any real progress can be made in individual health supervision, the supervisors themselves must be taught not only the facts of life and health, if they do not know these, but also how to impart such knowledge to others, and what their real responsibilities are as to the health of their working forces.

The health of the supervisor himself or herself is of paramount importance, not only as regards the quality of supervision, but also as it affects relationship to individual employees. The management officials of industrial organizations, where feasible, should provide thorough physical examinations of all supervisors and an adequate system for the follow-up and correction of defects and impairments which are found. Starting with the supervisor's own health and working environment is the best point of departure for the development of the entire industrial health program. Moreover, it is certain that unless the supervisor is " sold " on health, few if any of his or her fellow workers will become health-minded. As a matter of fact, the health program in industry must be developed from the top down, so far as officials and workers are concerned, rather than to attempt to push it from the bottom upward through the lines of organization.

Where practicable and feasible, all supervisors or prospective supervisors should be taught the principles of mental hygiene in order that they may form wise mental habits of their own, and that they in turn may be proper guides to their working forces. In this way the number of maladjusted supervisors and workers may be markedly reduced.

Supervisory training on health may be carried on through (1) short courses, conferences or periodic written instructions for supervisors already in service; or (2) systematic training and organized instruction on health in connection with job training for new employees and prospective supervisors. Supplying facilities, materials, and equipment for the use of supervisors in connection with their training and to enable them to carry on their duties as health counsellors to their workers, is

an important phase of management's responsibility.

As an example of one form of health training for supervisors, reference is made to a plan inaugurated a few years ago by the American Telephone and Telegraph Company and Associated Operating Companies in the Bell System in order to be of assistance to supervisors in fulfilling their opportunities as regards the health problems of employees. A series of so-called "Health Supervision Instructions," in mimeographed form, have been sent out at intervals of about a month for wide distribution to men and women supervisors in the various departments. These have covered such subjects as The Common Cold; Ventilation; Common Ailments, such as Headaches, Skin Disorders, Nervous Disorders, Indigestion, and Constipation; Healthful Vacations with emphasis on protection against sunburn, poison ivy, and so-called vacation typhoid; Mouth and Dental Hygiene; Food and Health; and Preventable Disease Control. Evidence is available which would seem to indicate that such periodic "Health Supervision Instructions" are of very great value to supervisory people in their daily tasks of dealing intimately with the personal health problems of individual workers; it is a method which apparently may fill an important place in the industrial health program, particularly when formal group or class health training is impossible.

In closing, it may be stated that if the working forces in industry are to become health-minded, the supervisory organization must assume the leadership. In carrying on his or her duties the supervisor needs the support and assistance of operating management and of the health specialists, such as doctors, dentists, engineers, nurses, and nutritionists, but the results achieved will depend largely upon the supervisor's own efforts. In former times health was neither an industrial subject nor objective; the manufacturing or operating supervisor concerned himself or herself with job routine only and was not supposed to assume any responsibility for the health status or safety of fellow workers. At the present time, with industrial health becoming something more than control of specific occupational hazards, personal health guidance of working forces should become an essential part of supervisory routine. The industrial supervisor of the future must have a dual responsibility—that toward the actual work at hand and that toward and with the worker supervised; he will promote not only industrial safety, but industrial health as well!

Industrial Hygiene Activities in the United States*

R. R. SAYERS, M.D., F.A.P.H.A., AND J. J. BLOOMFIELD, F.A.P.H.A.
Senior Surgeon, and P. A. Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

THE United States Census for 1930 shows that, at that time, there were approximately 49 million persons gainfully employed in the United States. Of this number, manufacturing, mechanical and mineral industries accounted for nearly 15 million workers. If the term "industrial hygiene" means the protection of the health of the worker, it is at once apparent that it is a major problem in public health.

More important than specific occupational diseases associated with the industrial environment is the fact that the incidence of other diseases, such as tuberculosis, pneumonia, and degenerative conditions, are greater among the industrial workers than the general population. It has also been shown that the life expectancy of the industrial worker is less than that of the nonindustrial worker.

In recent years large industrial establishments have contributed much toward the protection of the health of their workers. However, as nearly 90 per cent of the plants in the United States employ less than 100 persons, many establishments are not prepared to handle effectively the problem of industrial hygiene alone. It would seem, therefore, that the protection of the health of our workers is indeed an important health function and one which can be handled best through a governmental agency, such as a state or local department of health coöperating with the employers and workers.

PRESENT TRENDS IN INDUSTRIAL HYGIENE

Responsibility for safeguarding the health of industrial workers rests chiefly with state and local governments. The federal government's agencies concerned with industrial hygiene are engaged in collection and dissemination of information, conducting field studies, laboratory research, and protection of the health of federal employees.

The branches of the federal government engaged in this field, together with their respective activities, are as follows:

1. The Department of Labor, through its Children's Bureau, Women's Bureau, Bureau of Labor Statistics, and the recently created Division of Labor Standards, confines its activities to the collection of statistics on accidents, occupational diseases, wages, hours of labor, employment trends, and allied subjects. Through coöperation with the several states, the Department of Labor attempts to secure uniform laws, regulations, and practices for the protection of employed persons.
2. Studies in the mineral and allied in-

dustries have been conducted for many years by the Department of the Interior, Bureau of Mines, for the purpose of promoting the health and safety of workers employed in these industries.

3. In the Treasury Department, the Public Health Service, Office of Industrial Hygiene and Sanitation, conducts studies concerned with the health of industrial workers. Particular attention has been given to industrial dusts, specific industrial poisons (notably lead, radium, benzol, and carbon monoxide), dermatoses, ventilation, illumination, and industrial morbidity and mortality. Investigations of both field and laboratory type are made. These are designed to yield information regarding the extent and nature of a particular hazard throughout industry and to devise control methods. The investigations are made in coöperation with state and local authorities and the data obtained serve to guide industrial, as well as governmental establishments, in coping with occupational diseases.

On behalf of state and territorial health officers, the Public Health Service has been instrumental in bringing about agreements with the chemical industry beneficial to the health of those working in the industry, and also to those using its products. The agreements cover such poisonous materials as tetraethyl lead, methanol, liquid chlorinated hydrocarbons, carbon tetrachloride, carbon disulphide, and aniline oil. Standards of health and safety are developed through the coöperative efforts of the Public Health Service, Bureau of Mines, Department of Labor, and American Standards Association.

Compensation of civilian federal employees for injuries or diseases proximately caused by conditions of employment is administered by the independent Employees Compensation Commission. Medical personnel needed for administrative purposes in this work are provided by the Public Health Service.

Except for federal and territorial employees, legal protection of the industrially employed is a responsibility reserved by state and local governments. Prior to this year, most states have concerned themselves chiefly with matters of safety, sanitation, employment of women and children, and compensation of employees following accidents. All but two states have workmen's compensation legislation for accidental injuries, and approximately 15 states provide compensation for one or more occupational diseases. Administratively, the states have placed enforcement of occupational disease legislation in various departments. Several states require reporting of occupational diseases.

As will be developed in this discussion, the past year has seen a rapid growth in the establishment of industrial hygiene units in health departments. There has also been a realization, upon the part of those responsible for the administration of occupational disease units, that a coöperative program among the various governmental agencies involved is desirable for effective progress in this important phase of public health.

So far a brief summary has been presented of the activities of various governmental or official agencies. An increasing amount of interest in both the study and control aspects of occupational diseases has also been manifested by nonofficial agencies, particularly large industrial establishments, insurance companies, as well as universities and national organizations directly interested in public health, notably, the American Public Health Association, the American Medical Association, the National Safety Council, and the National Tuberculosis Association. Not only have industrial establishments shown a great deal of interest in this subject, and in many instances inaugurated programs of industrial hygiene, but there has also been an awakening on the part of the worker himself to the need for coöperation in the control of industrial health hazards.

In many of the studies conducted by the Public Health Service and other agencies, the workers have shown an excellent coöperative spirit and have submitted themselves for complete medical examinations in order that the etiology and control of industrial health hazards might be determined by scientific means.

Students of the industrial hygiene and sanitation problem have long realized that actual progress in this field could be made only through a concerted effort by both state and local governments. Although many state health officials realized that industrial hygiene was an integral part of their health activities, they were unable to cope effectively with this problem, due to the lack of funds and interest on the part of those persons most directly concerned. For many years the Conference of State and Provincial Health Authorities of North America have sustained interest in industrial hygiene through their Committee on Industrial Hygiene. Passage of the Social Security Act at once made necessary funds available for the extension of this phase of public health in various states. Accordingly, the Public Health Service, in coöperation with the Industrial Hygiene Committee of the Conference of State and Provincial Health Authorities inaugurated a program designed for the purpose of establishing active industrial hygiene units in the health departments of various industrial states.

TABLE I

CLASSIFICATION OF STATES ACCORDING TO THE POPULATION AND NUMBER OF GAINFUL WORKERS IN EACH STATE, AND NUMBER AND PER CENT IN MANUFACTURING, MECHANICAL, AND MINERAL INDUSTRIES, U. S. CENSUS, 1930

State	*Total Population*	*No. of Gainful Workers*	*Number of Gainful Workers in Manufacturing, Mechanical and Mineral Industries*	*Per Cent of Gainful Workers in These Industries*
New York	12,588,066	5,523,085	1,995,924	36.0
Pennsylvania	9,631,350	3,722,428	1,796,944	48.2

Wyoming	225,565	92,451	19,046	20.7
North Dakota	680,845	240,317	18,095	7.5
Nevada	91,058	42,885	11,776	27.4

The following discussion presents certain information on what has been accomplished to date in establishing industrial hygiene units in the various state and local health departments.

Tables I and II represent an attempt to classify the states according to population and the number of gainful workers in each state, as well as the number and per cent in manufacturing, mechanical, and mineral industries. The order in which these states are presented is based on the number of persons employed in these three industries. However, in order to take into consideration those states having small but highly industrialized populations, there has been included in Table I a list of these smaller states.

A study of Tables I and II shows that approximately 49 million persons were gainfully employed at the time of the last decennial census. Of this number, manufacturing, mechanical, and mineral industries accounted for 15 million workers. The occupational exposures known to exist among this large group of workers embrace more than 500 poisonous materials and hazardous conditions which may be detrimental to health. In fact, as previously stated, numerous studies of the health of industrial workers which have been made by the Public Health Service and other agencies show that certain of these workers experience high morbidity and mortality rates and that the industrial occupation is an

important factor in the causation of excessive illness and mortality rates.

Experience has indicated that, in order to carry out an effective program of industrial hygiene, certain minimum activities are essential. For the sake of brevity, these activities have been divided into administration and field investigations, as presented below.

ADMINISTRATION

1. Arrange for securing and investigating reports of occupational diseases to the state department of health.
2. Secure reports of all diseases for which sick benefits are paid by industrial sick benefit organizations in the state department of health.
3. Coöperate and provide a source of information for other state departments, such as industry, labor, insurance, and medical interests, or any agency interested in industrial hygiene.
4. Educational program to acquaint industry and various groups interested as to importance of the problem.

FIELD INVESTIGATIONS

1. Preliminary survey to determine the scope and nature of the industrial hygiene problems in the state.
2. Surveys by field personnel of plant conditions causing or suspected of causing occupational diseases, in order that the department may advise or make recommendations for the control of existing or potential health hazards.

It is believed that the functions given herein are sufficiently clear to require no further elucidation. Although there may be many other activities in which an industrial hygiene unit may take part, it is felt that the tentative program just outlined should serve as a starting basis.

The outline map which follows indicates graphically the progress which has been made by the Public Health Service in the establishment of industrial hygiene units in health departments.

Prior to 1936 there were only 5 state departments of health conducting industrial hygiene activities, these activities being of a limited nature. This number has been increased to 17, and it is felt that many more states will soon include industrial hygiene as one of their functions.

INDUSTRIAL HYGIENE UNITS IN THE UNITED STATES

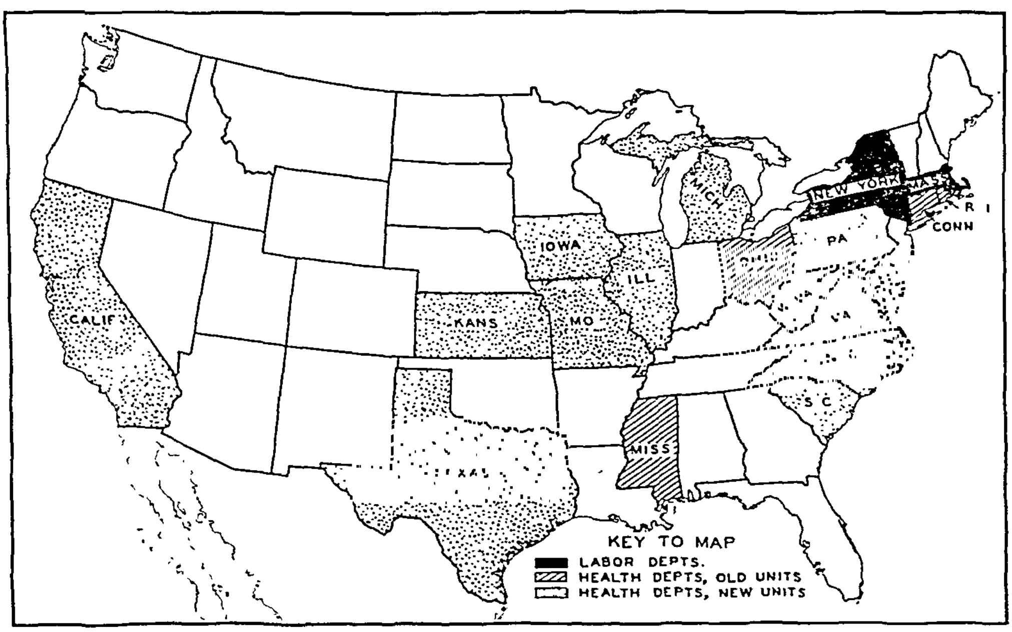

TABLE III

INDUSTRIAL HYGIENE ACTIVITIES IN CERTAIN STATE HEALTH DEPARTMENTS

State	Number of Gainful Workers	Annual Budget: Prior to 2/1/36	Present or Proposed: Total	Present or Proposed: Per Worker
California	2,500,969	......	$7,720	0.003
Connecticut	677,292	$11,927	24,295	0.031
Illinois	3,184,875	......	28,250	0.009
Iowa	912,832	......	9,600	0.010
Kansas	694,276	......	9,600	0.014
Maryland	672,906	7,000	12,000	0.018
Michigan	1,927,498	......	42,400	0.022
Mississippi	844,887	4,500	6,200	0.007
Missouri	1,458,054	......	16,680	0.011
North Carolina	1,141,129	......	27,500	0.024
Ohio	2,615,938	5,200	33,200	0.013
Pennsylvania	3,722,428	......	40,220	0.011
Rhode Island	297,168	2,250	23,000	0.077
South Carolina	687,721	......	10,800	0.016
Texas	2,207,118	......	23,100	0.010
Virginia	880,276	......	14,900	0.017
West Virginia	570,459	......	19,000	0.033
Total	24,995,826	$30,877	$348,465	0.014

1. The States of New York and Massachusetts have Industrial Hygiene Divisions in the Labor Department, so that in all, 32,333,333 gainful workers are provided with industrial hygiene facilities; there are still 16,255,397 workers who are not provided with industrial hygiene services.
2. In 1934, New York State alone paid out $531,808 in compensation for occupational diseases.

Perhaps a better conception of the growth in this field may be had from a study of Table III. Prior to the passage of the Social Security Act, only $30,877 was being expended by the 5 states carrying on industrial hygiene in health departments. The latest budgets for industrial hygiene in the 17 states and cities carrying on this type of activity are now approximately $350,000, or more than 10 times the amount expended heretofore. However, even this increased expenditure shows a per worker cost of only 14 mills, an amount rather negligible when considered in the light of expenditures for other public health activities. When we realize that New York State alone paid out $531,808 in compensation during the year 1934 for occupational diseases which are in a large measure preventable, then we know that even our present growth for this activity is none too great. A further study of Table III shows that nearly 33 million gainful workers are now being provided with industrial hygiene facilities, leaving approximately 16 million persons

TABLE IV

MINIMUM REQUIREMENTS FOR STATES HAVING A SMALLER INDUSTRIAL POPULATION

(¼ million or less industrial workers)

Personnel	*Cost*
1 Physician Director	$5,000–$6,000
1 Industrial Hygiene Engineer (chemical engineer)	3,000– 3,600
1 Chemical Engineer (laboratory and field)	2,400– 3,000
1 Stenographer	1,200– 1,500
Equipment	4,800
Supplies	1,000
Travel	2,000
Total cost:	$19,400–$21,900

for whom no such provisions have as yet been made.

Tables IV, V and VI present the minimum requirements for various states in the way of personnel, equipment, and annual expenditures. These lists should be considered as very flexible and are to be modified with the particular needs of each locality. They are offered merely as a working basis for those states about to inaugurate industrial hygiene programs.

One of the serious problems which confronted the Public Health Service in connection with establishing industrial hygiene units in state departments of health was the shortage of trained personnel. It is well recognized that the practice of industrial hygiene and sanitation requires highly specialized training. A doctor or engineer undertaking this type of work should not only have a thorough grounding in public health work, but should also be well trained in such subjects as ventilation, illumination, industrial toxicology,

TABLE V

MINIMUM REQUIREMENTS FOR STATES HAVING LARGE INDUSTRIAL POPULATIONS

Personnel	*Cost*
1 Physician Director	$5,000– $7,500
1 Assistant Physician	4,500– 6,000
1 Industrial Hygiene Engineer (chemical engineer)	3,600– 5,000
1 Industrial Hygiene Engineer (ventilation engineer)	3,600– 5,000
1 Stenographer	1,200– 1,500
Equipment	
(A laboratory for carrying on industrial hygiene studies by the Engineering Section of the Bureau)	2,500
Physician's Equipment	
(X-ray, microscope, etc.)	4,000
Supplies	1,500
Travel	3,000
Total cost:	$28,900–$36,000

TABLE VI

CONTEMPLATED PERSONNEL AND BUDGET FOR A LARGE INDUSTRIAL STATE

Personnel	*Cost*	
1 Physician Director	$7,500	
1 Chief Industrial Hygiene Engineer	6,000	
3 Physicians, at $5,000	15,000	
1 Ventilation Engineer	4,000	
3 Chemical Engineers, at $3,000	9,000	
1 Chief Chemist	4,000	
1 Assistant Chemist	2,500	
1 Statistician	3,500	
1 Nurse	2,000	
2 Medical Technicians, at $2,000	4,000	
2 Engineering Technicians, at $1,500	3,000	
5 Stenographers, at $1,500	7,500	
Total salaries:		$68,000
Laboratory Supplies and Equipment		
Equipment	$7,500	
Supplies	2,500	
Travel	7,500	
Miscellaneous	1,500	
Total:		19,000
Grand Total:		$87,000

dust determinations, and various other specialized subjects pertaining to industrial health. Perhaps it may be well to consider the duties and qualifications that have been suggested by the Industrial Hygiene Committee of the Conference of State and Provincial Health Authorities of North America for the chief medical and engineering personnel of such a unit. According to this committee, the duties of the medical director of such a unit are given as:

> Under administrative direction, to plan, correlate, and direct the activities of the Bureau of Occupational Diseases of the Department of Health; and to do related work as required.

For minimum qualifications this committee gave the following requirements:

Graduation in medicine from an institution of recognized standing, preferably with specialization in industrial hygiene and training in public health, a license to practise medicine, and 2 years' graduate work in industrial hygiene including ventilation, illumination, industrial toxicology, and methods of dust determinations, and 3 years' experience in public health work in relation to effect of industrial environment on health—at least 1 of which shall have been in directive capacity, or any equivalent combination of education and experience; advanced knowledge of the principles and practices of medicine and surgery, with particular reference to the control and elimination of industrial hazards and occupational diseases; especial ability to diagnose occupational diseases and to ascertain the specific causes of such diseases; ability to make comprehensive analyses of health conditions in industries, to draw adequate conclusions, and to prepare clear and informative reports for publication; initiative; tact; good judgment; and good address.

The duties of the industrial hygienist or industrial hygiene engineer were given as—

To determine, under direction, the necessity of making specific studies of particular industrial conditions; to conduct surveys and supervise studies of factory conditions predisposing to occupational diseases; to prepare comprehensive reports of findings with recommendations for control of occupational disease hazards; to supervise the work of field and laboratory workers; and to do related work as required.

The minimum qualifications called for—

Graduation in chemical engineering, with 2 years' graduate work in industrial hygiene: to include ventilation, illumination, industrial toxicology, dust determinations; 3 years' experience in surveys and studies of industrial conditions for occupational disease control; or any equivalent combination of education and experience; familiarity with materials and processes used in industry; thorough knowledge of physical and chemical procedures for necessary determination of occupational disease hazards and of methods of control of these hazards; ability to recognize industrial processes and materials presenting potential occupational disease hazards; ability to establish contacts with plant executives; ability to enlist coöperation of plant executives, foremen and laborers; initiative; tact; good judgment; and good address.

During the next few years personnel trained in industrial hygiene and sanitation will be more and more in demand. The various universities engaged in teaching public health should give serious consideration to the inclusion in their curricula of rather comprehensive courses in industrial hygiene and sanitation. As a matter of fact, some of our leading universities are already cognizant of this need and are now planning to give intensive courses in industrial hygiene, either as part of their medical curriculum or to include such courses in their schools of public health and hygiene.

To overcome the present lack of trained personnel in the 17 states which have just inaugurated industrial hygiene programs, the Public Health Service has evolved the following procedure: Since one of the prerequisites for a career in industrial hygiene is that an individual should have a background of public health, it has been suggested to the various state health officers that they consider transferring one of their physicians and one of their sanitary engineers to this new activity, and by giving them an intensive course in industrial hygiene, help them to undertake this new field of endeavor. This particular plan also has an advantage in that the individual is a resident of the state, and in all probability is thoroughly familiar with its industries, and the policies of the state department of health and other state agencies. Such a procedure has been especially successful in some of the states where industrial hygiene units have already been established.

In order to introduce these individuals to industrial hygiene procedure, the Public Health Service conducted a seminar for physicians and engineers from state health departments. The

attendants at this seminar included 33 physicians and engineers from 17 states. It is realized, of course, that 1 month's lectures and laboratory demonstrations only served to introduce these students to the subject of industrial hygiene. Therefore, it is planned to supplement this course by actual aid to the various states, in order that the personnel may obtain advice and training under practical working conditions. It is proposed that demonstrations in industrial hygiene may be conducted in various industries in the states. One such demonstration has already been completed in North Carolina, where the Public Health Service, in coöperation with the new Industrial Hygiene Division of that state, conducted a study of asbestosis in certain asbestos textile plants. Similar aid is being given to the State of West Virginia, and it is hoped to extend such service to other states which may call on the Public Health Service for aid in initiating this new activity. With such a plan, it is possible to perform a dual function; namely, the Office of Industrial Hygiene and Sanitation of the Public Health Service will be conducting field studies among the industrial workers, designed for the purpose of yielding information on the extent, nature, and control of certain hazards, and at the same time will be aiding the state personnel in obtaining first-hand training in the conduct of industrial hygiene activities.

FUTURE DEVELOPMENTS IN INDUSTRIAL HYGIENE

The past few years have shown a tremendous interest and activity on the part of the health departments and other agencies in the field of industrial hygiene and a realization that, in order to improve the health of the worker, a coöperative effort should be made by all those responsible for safeguarding the health of the working population. During the past year the number of state and city departments of health carrying on an effective program in industrial hygiene has increased to the point where nearly two-thirds of the working population are receiving some consideration on industrial health problems. Present trends indicate that more states will gradually undertake such work, rendering effective service to industry, labor, and other agencies interested in such a program. It is realized, of course, that this development will necessarily be slow, but there is no reason to feel that it will ever retrogress. Industrial hygiene has come to stay, and should be one of the most active fields of public health in the near future. The Public Health Service will be glad to have the various states look to it for guidance and assistance. As an aid to such a program, members attending the recent seminar unanimously voted that a conference of official industrial hygiene workers be formed. The objects of this conference would be to promote industrial hygiene and sanitation in all its aspects and phases, to coördinate industrial hygiene and sanitation activities in official federal, state, and local and territorial organizations; to encourage interchange of experience among industrial hygiene workers in official administrative positions; to collect and make accessible to all industrial hygiene workers in official administrative positions such information and data as might be of assistance to them in the proper fulfillment of their duties. Plans for such a conference are now under way.

With the increased service by the state agencies to industry in solving the manifold problems of industrial hygiene, the Public Health Service should be able to devote more of its time to much needed research in the field of industrial toxicology, and to those field studies of a broader nature designed

to evolve standards to be applied by local governmental agencies. The combined efforts of the federal and local governments should bring about a definite improvement in the health of the industrial worker.

What Is Scarlet Fever?

DURING recent years bacteriologists have been very active in their efforts to throw light on the nature of the infection in scarlet fever and allied diseases. The great increase in new forms and types of streptococci, and the ingenuity displayed in their nomenclature—well described by Topley and Wilson as a "riot of christening"—are sufficient to confuse the physician who is faced with the actual clinical and administrative problems connected with these diseases. There is conclusive evidence that uncomplicated scarlet fever is due to infection by one or other of many different strains of the haemolytic streptococcus; but organisms with the same morphological and biochemical reactions are to be found, not only in widely varying forms of disease and in those who have recovered from these diseases, but also in anything up to 36 per cent of apparently healthy persons.

The Dick test and the Schultz-Charlton reaction may be useful in diagnosis; but they are of limited value, and least reliable in the very type of cases in which their help is most needed. On what, then, is the clinician to rely in trying to arrive at a diagnosis?

Medical practitioners have always regarded the typical scarlatiniform punctate erythematous rash as the diagnostic feature *par excellence*, and subsequent consistent desquamation as clinching the diagnosis; but experienced observers have always been baffled to find patients with typical rash and strawberry tongue who did not peel, and other patients with typical peeling who have had no previous rash.

In a recent bacteriological investigation of 100 suspicious cases, Brown and Allison found that the incidence of rashes was almost equal in the bacteriologically positive and negative cases; that evidence from the tongue, temperature, and pulse-rate was of no diagnostic value; and that only 40 per cent of the positive cases eventually showed consistent desquamation.

Even after the most thorough clinical and bacteriological investigation, the diagnosis of scarlet fever may be beset with extreme difficulty; and with the mild type of the disease now prevalent it is recognized to be one of the most difficult to diagnose of all infectious diseases. It is the busy general medical practitioner, however—with little or no time and facilities for bacteriological and serological tests—who has the responsibility of not only diagnosing but notifying a condition which cannot be regarded as a specific epidemiological entity. It is, therefore, not a matter for surprise that in a large percentage of patients, notified and admitted to hospital, the diagnosis of scarlet fever is not confirmed—Brown and Allison estimate that 39 per cent of doubtful cases of scarlet fever are not infectious and do not require hospital treatment of any kind. —Andrew W. Forrest, M.A., M.D., Ch.B. (Edin.), D.P.H., Scarlet Fever Control on Modern Lines. *Pub. Health*, 49, 12:412–13 (Sept.), 1936.

employees 25 years ago, the circus immediately adopted and still rigidly adheres to the policy of requiring every employee to be vaccinated against smallpox.

SANITARY EQUIPMENT AND PRACTICES

The conditions found in the sanitary survey are summarized in the following: *

1. WATER (SOURCE)

The advance men, or so called "24-hour men," make a contract in each city for water to be furnished on the day or days that the circus is to be at that locality. Usually it is a municipally owned water supply, but sometimes it is owned by a private water company under municipal control. No specifications as to standard of purity were included in the contract.

Water on the circus grounds is used for the following purposes: (a) For drinking water and other domestic use in the cookhouse and about the grounds; (b) for watering the animals; and (c) for sprinkling. Safety of the water is much less essential for the latter two purposes than for the first, except for the fact that men in the horse "tops" commonly drink from the same bucket from which the horses are served. All tanks on wagons and trucks on the circus grounds were filled from the top by means of a fire hose inserted into the tank.

The method of serving drinking water was found to be exceedingly crude in most instances, the prevailing custom being to use a barrel, keg, or bucket with ice immersed in the water, and the water was served to the individual by means of a common dipper or cup.

Water on the Sleeping Cars—Each sleeping car is equipped with overhead tanks averaging about 300 gallons per car. Water from these tanks is said to have been used for lavatory purposes only. These tanks are filled ordinarily from the railroad yard supply, which is separate from that from which the circus lot supply is derived. Water for filling the car tanks is secured by means of direct hose-to-hose connection with the city supply. There is a permanent hose line installed on top of cars so that the nozzles emptying into the storage tanks never come in contact with surface dirt or filth.

Drinking water on the cars was said to be derived entirely from ice placed in coolers and allowed to melt. There are abundant indications, however, that, during the extremely hot weather, the melting ice did not furnish sufficient water to meet the demands, and that it was supplemented by water from storage tanks, which was in all probability safer for drinking purposes than water from melted ice, as the ice was necessarily subjected to contamination by handling. Water drawn from the coolers was served to the individuals by means of cups and glasses used more or less in common with other occupants of the car.

2. LATRINES (ON THE CIRCUS GROUNDS)

Nothing worthy of the name of latrine was found. It was customary to dig a shallow trench or none at all over which was installed a straddle bar or, in a few instances, a seat arrangement, with no attempt to exclude flies. The principal function of the so-called "latrine," however, was to afford privacy from public view by means of canvas side walls.

Toilet Facilities on the Cars—The cars were equipped with galvanized iron buckets swung under each toilet commode for use when the cars were parked. No disinfectant or fly repellent was used. The contents of these con-

* Extract from "A Report on an Epidemic of Typhoid Fever in a Circus," by K. E. Miller, Senior Surgeon, and H. E. Miller, Special Expert, U. S. Public Health Service.

tainers were supposed to be disposed of by earth burial, but there are grounds for speculation as to the efficiency of this service.

3. COOKHOUSE

(a) *Dishwashing* — The equipment in each instance consisted of 2 tubs of water, 1 for washing the dishes and 1 for rinsing. The temperature of the water was ordinarily little more than lukewarm. Both wash and rinse water became heavily charged with food particles, so that the solution commonly resembled a thick soup. Dishes withdrawn from the rinse water were seen to have numerous food particles still clinging to them. Dish towels soon became water-soaked and laden with grease and food particles.

(b) *Protection Against Flies*—Bread and other food supplies on the tables and in the kitchen were not sufficiently guarded against flies.

(c) *Food Handlers*—Cleanliness of outer garments and personal cleanliness were found considerably below standard. The custom in serving meats and many other foods to the plates was by the hands direct, without the use of serving forks or other suitable instruments. Physical examination of food handlers had not been carried out, and no stool examinations for typhoid carriers had been made. Mixed garbage and refuse of all kinds were disposed of by dumping on the surface of the ground.

4. TYPHOID INOCULATION

No effort had been made to require or encourage individual antityphoid prophylaxis. Only 143 gave history of previous typhoid inoculation.

SANITARY MEASURES INSTITUTED

Although the findings fail to indicate any source within the circus itself which could have been held responsible for the epidemic, the following sanitary measures were instituted by the circus management, upon recommendation of officers of the U. S. Public Health Service, to safegard against secondary cases and provide the maximum protection for the future through precautionary practices applicable to conditions under which the circus operates:

1. The advance men were required to secure statements from the local health officer certifying that the water supply conforms to the standards for interstate traffic, that the ice contracted for is from an approved source, and that the milk is of a safe quality and pasteurized.

2. Water was required to be taken only from hydrants designated by a responsible employee of the water company and opened by him personally or by his representative.

3. Water tanks were remodeled so as to prevent the insertion of a hose into the tank.

4. All water tanks, storage tanks on cars, and cooler tanks were chlorinated once each week.

5. All containers for dispensing drinking water were replaced by covered coolers with spigots. The coolers were so constructed that ice should not come in contact with the drinking water.

6. The common dipper or cup was prohibited, and replaced by single service paper cups.

7. Each unit of the circus was equipped with adequate latrine facilities. Also suitable latrines were provided for public use. The latrines consist of an earth pit, usually 3 feet deep, and covered at the top by a collapsible fly-proof steel latrine seat. When placed over the latrine pit the earth is banked around where the bottom rests upon the ground so as to insure against the entrance of flies. The seat openings are covered with fly-tight lids. Sufficient chloride of lime is used to

repel flies, destroy odors, and disinfect the latrine contents. In the men's latrines there is an accessory urinal trench, which also is generously treated with chloride of lime. These latrines were placed under constant supervision by circus attendants. The location of these latrines must be satisfactory to the local health officer.

8. In the cookhouse, temporary improvement in the dishwashing arrangements was effected by requiring all dishes, after being rinsed, to be passed through a chlorine sterilizing bath. As a permanent measure, however, the order was placed for a dishwashing machine to be mounted in a special truck, together with its own power unit and water tanks, whereby hot and cold water can be supplied under pressure. This unit was delivered at St. Louis on August 11, and is reported to have been in constant and efficient use ever since.

Food on the table and in the kitchen was guarded against flies by coverings in so far as practicable.

Food handlers were placed under rigid supervision as regards clothing and personal cleanliness. The serving of foods by means of proper utensils was required. All food handlers were physically examined for tuberculosis, venereal disease in communicable form, and all other communicable diseases. In addition, two samples of stools and urine were taken from each to rule out any typhoid carriers. All reported positive were immediately discharged and returned home in custody of local health officers.

As regards garbage disposal, the first requirement was a separation of food refuse from tin cans and combustible material. The latter was burned before the site was abandoned. For the food refuse, an earth pit of suitable proportions was dug near the kitchen. The garbage during the day was deposited in this pit, which was covered over with earth at the end of the day. In some cities the garbage was deposited directly into garbage trucks furnished by the city.

The entire circus personnel was subjected to antityphoid inoculation.

As a surety that every phase of health protection for the circus personnel and the public will be adequately guarded in the future, the circus engaged two additional employees for the remainder of the season. One of these is a medical man to have charge of the medical phases of health protection, and the other a highly trained and experienced sanitary supervisor. The employment of a sanitary inspector has been continued.

The following regulations were prepared for the circus and have been adopted by the circus management as the standard of sanitary practice:

COOKHOUSE

1. *Water Supply*—
   - a. The drinking water shall be secured from the tank designated as drinking water supply tank.
   - b. Water for drinking shall be from the standard covered drinking water coolers, equipped for spigots for drawing water.
   - c. Drinking water shall be served only in clean individual service paper cups.
   - d. The use of the common drinking cup or dipper and the practice of dipping drinking water are expressly forbidden.
   - e. All ice used in water coolers shall be thoroughly rinsed with clean water after breaking and before being placed in coolers.
   - f. All coolers shall be kept clean at all times and thoroughly sterilized once each week in accordance with the instructions of the Superintendent of Sanitation.

2. *Food Handling*—
   - a. All food shall be protected against flies, dust, and other sources of contamination to the greatest possible extent at all times, by means of covering and through other practical measures.

b. All cookhouse employees (especially cooks and waiters) shall wear clean outer garments and present evidence of personal cleanliness. All employees handling food shall wash their hands thoroughly with soap and water before entering on duty. All cookhouse employees shall wash their hands thoroughly with soap and water after each visit to the toilet while on duty before returning to duty.

c. Wash basins and individual towels, either paper or cloth, adequate both as to number and distribution, shall be provided at all times for the use of cookhouse employees.

d. All dishes, after being washed, shall be removed from the dishwashing machine, stored, and handled in a manner to prevent soiling or recontamination.

e. Health certificates: Each food handler shall have a certificate from a properly qualified health officer attesting the fact that he is free from venereal disease in a communicable form, is free from evidence of tuberculosis or other communicable disease, and is free from evidence of being a typhoid fever carrier, as indicated by two or more successive stool cultures. The certificate shall also show that he is immune to smallpox and has been inoculated against typhoid fever in the past 3 years. The health certificate shall not be considered valid after 6 months.

3. *Garbage Disposal*—All garbage and refuse must be separated.

a. All paper, trash boxes, and other combustible material shall be collected so as to prevent a nuisance.

b. Table scraps and other organic garbage shall be collected in covered, water-tight, metal garbage cans. Distribution of cans as to number and location shall be adequate to provide for the collection of garbage at all points where garbage accumulates.

c. Except where garbage is collected from the containers by the city or some other agency which will wholly remove same from the grounds, all garbage shall be buried with at least 2 feet of earth, in accordance with instructions of the Superintendent of Sanitation.

4. In addition to the foregoing, all other practicable measures for insuring the safety of food shall be carried out at all times in accordance with the instructions of the Superintendent of Sanitation.

NOTE: In all towns the "24-hour man" shall use every effort to get a covered garbage wagon to remain at the cookhouse during show day.

FOOD DISPENSED TO THE PUBLIC

Sanitary regulations governing the cookhouse shall apply in all respects to all candy butchers and other persons in any way engaged in preparation or dispensing of food to the public, with the following exceptions:

1. When hand dishwashing is done, the dishes shall first be washed in hot water with soap or washing powders, passed through a clean hot water rinse, and again rinsed in a rinse water treated with chlorine to sterilizing strength.

2. Dish towels shall be boiled and rinsed through chlorine sterilizing solution after each use.

3. The cooling water in which all bottled goods are cooled shall at all times be treated with chlorine to sterilizing strength.

DISTRIBUTION AND SERVICE OF DRINKING WATER

1. The use of the common drinking cup or dipper and the practice of dipping drinking water are expressly forbidden. Single service paper drinking cups shall be provided in sufficient quantity at all water coolers.

2. All water coolers shall be kept clean, shall be kept covered, and shall be sterilized with hypochlorite of lime once each week, in accordance with the instructions of the Superintendent of Sanitation.

3. Circus water tank wagons shall be the only source of water supply used for filling drinking water coolers.

INSTALLATION AND MAINTENANCE OF LATRINES

1. The initial operations of setting up equipment of any department on the circus lot shall include the installation of the latrines and urinal trenches for the department.

2. Chloride of lime shall be applied to latrine trenches and urinal trenches in accordance with the instructions of the Superintendent of Sanitation.

3. The foreman in charge of the department shall be responsible for the sanitary maintenance of latrines serving the department.

FILLING TANKS AND TANK TRUCKS

1. No person connected with the circus, except those responsible for filling the tanks, shall be permitted to take water from any hydrant or other source.

2. The hydrants from which water is taken shall not only be pointed out by a responsible employee of the contracting company, or city, in person, but shall be opened by him or under his direct supervision.

3. Water for all purposes on the circus lot shall be obtained from the circus tanks.

4. All circus water tanks shall be maintained at all times in such condition as not to impair the quality of the water in the tanks or render the same unfit for drinking.

5. The hose used for filling tanks from the hydrants shall be handled at all times in such manner as to prevent the soiling or contamination of surfaces that come in contact with the water discharged into the tank.

6. All circus water tanks shall be sterilized once each week with chloride of lime in accordance with the instructions of the Superintendent of Sanitation.

WATER SUPPLY AND EXCRETA DISPOSAL FOR CARS

1. *Water Supply*—Coolers and tanks on cars shall be filled only from—

a. The approved drinking water supply source in railroad yards approved by the U. S. Public Health Service for use on Pullman and railway passenger cars, or

b. A hydrant on the public water supply system, which shall not only be pointed out by a responsible employee of the contracting company, or city, in person, but shall be opened by him or under his direct supervision.

c. The hose and other equipment used for filling tanks and coolers shall be handled in a sanitary manner, and the surfaces which come in contact with the water shall be protected against contamination from handling or by soiling with dirt or filth.

d. All ice used in coolers shall be clean artificial ice. All ice shall be thoroughly rinsed with clean water after it has been broken and before being placed in coolers.

e. All persons engaged in handling or the distribution of drinking water or in handling ice used in coolers shall conform to the requirements of the health certificate and personal cleanliness as prescribed for food handlers.

2. *Excreta Disposal*—

a. All excreta cans shall be emptied as required to prevent a nuisance.

b. Whenever the contents of excreta cans are not removed by a scavenger service in such manner as completely to remove all such material from the vicinity of the cans, the contents of cans shall be buried under a 2 foot covering of earth.

c. All excreta cans shall be treated regularly with disinfectant solution in accordance with the instructions of the Superintendent of Sanitation.

This investigation reveals a problem in sanitation in many respects peculiar in character and vast in its magnitude since it is more or less common to all circuses, carnivals, and ambulatory bodies. Carnivals probably present the most serious problem since they are more numerous, stay longer in one place, and are usually lower in scale as to equipment and character of management.

Furthermore, under the present conditions of lack of any uniformity of such state or local regulation as exists, it is humanly and economically impossible for the management of any circus or carnival that travels extensively to conform to all of the requirements and demands of all of the health jurisdictions encountered. One has only to travel with a circus a short time to become convinced of this fact. Many of the requirements imposed upon circuses by health officials are not applicable to circus conditions while others are useless and entail an immense amount of unnecessary expense.

Therefore, it is recommended that this Association appoint a committee to study the problem of the sanitary regulation of circusses, carnivals and other ambulatory bodies, and that the Conference of State Sanitary Engineers and the Conference of State and Territorial Health Officers be asked to appoint similar committees to collaborate with a committee from the

Public Health Engineering Section with a view to formulating suitable rules and regulations for the sanitary management of circuses, carnivals, and other ambulatory bodies to be recommended to all state and local health departments for adoption.

It is believed that this is one of the most urgent problems confronting health officials today, and that it can never be satisfactorily handled until state and local health officials agree upon and adopt some uniform set of requirements. Furthermore, it is believed that the managements of the various units of this vast industry will not only welcome such action, but will quite generally coöperate in the observance of reasonable, sensible uniform requirements.

More Enthusiasm for Cure than Prevention

THERE are social and economic reasons why we pay so much greater attention to individual sickness than to public health, why the pursuit of cure of disease is prosecuted so much more vigorously than the pursuit of prevention. But more important still is the absence of sensation which characterizes all real preventive work. It appeals to the intellect and not to the emotions and so fails to excite enthusiasm. The warrior, whose business is to destroy life, is loaded with honours, the physiologist, whose business is to save life, remains unknown. We had an interesting example of this in March, 1936, when on nearly the same day died our most popular admiral and the greatest physiologist of the 20th century. The politician has a more honoured calling than the dustman, but it is far less useful, for we know that if the politicians shut up for 6 months we should all breathe more freely, whereas if the dustman did, we should not be able to breathe at all. But to complain, as we often feel inclined to do, that the struggle for prevention is an up-hill game for which the public will not supply adequate funds and in which 9 persons out of 10 take little interest, is to complain of the level of human intelligence.—Dunstan Brewer, D.P.H., *Ann. Rep., Medical Officer of Health for the Year 1935*, Borough of Swindon.

The Question of Acid and Alkali Forming Foods*

JAMES A. TOBEY, Dr.P.H., F.A.P.H.A.
Director of Health Service, The Borden Company, New York, N. Y.

FADDISTS rampant in the realm of pseudo-science have seized upon the acid base balance of the body as an apt subject for their sophistry. As a consequence, much more is written and said on this topic than is warranted by known facts, and much that is so blandly asserted, especially for lay consumption, is distorted and incoherent.

The acid base balance is a condition in which the ratio of carbonic acid to bicarbonate in the blood is maintained in a definite state of equilibrium. Although alterations in the hydrogen ion concentration of the blood and body fluids may and do occur within certain narrow limits, such changes are due to serious disturbances of metabolism or in the functioning of body organs, usually the result of severe morbid conditions. The effects of foods on this acid base balance have been greatly exaggerated, for their influence in bringing about modifications in the chemical content of the blood is practically nil.

All foods may, of course, be classified chemically as acid forming, base forming, or potentially neutral. By calculating the equivalent in normal acid present in the form of chlorine, phosphorus, and sulphur; and the normal alkali in terms of the calcium, magnesium, potassium, and sodium in particular foods; relative values of excess potential acid or base can be expressed.

Such calculations reveal that foods of decided potential acidity include meats of all kinds, fish, shellfish, and eggs, while cereals and breadstuffs show a mild acidity. The base forming foods include most of the fruits and vegetables, with milk and cream displaying a slight potential alkalinity. The citrus fruits contain acid radicles, but these are burned in the body so that the end products are potentially alkaline. Pure fats, sugars, starches, and other foods devoid of minerals are neutral in their reactions.[1]

In the ordinary mixed diet which is the customary fare of the individual who has not succumbed to the wiles of a food fakir, the acid and base forming elements in the diet will be reasonably well balanced. According to some authorities, however, a slight preponderance of alkaline foods is desirable, possibly for the reason that normal blood is mildly alkaline, with a hydrogen ion concentration (pH) averaging 7.35.

The scientific basis for such a categorical recommendation seems, nevertheless, to be somewhat tenuous. Recent investigations reported by Bischoff *et al.*, have shown that there is no

---

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

significant difference in the acid base picture of the blood of normal individuals when they are fed mixed diets containing excessively acid or excessively alkali producing foodstuffs.[2] The ingestion of a quart of milk, a quart of orange juice, or a pound of bananas, all alkali forming foods, produced not even a temporary shift in the hydrogen ion concentration of the blood plasma, or in the alkali reserve. A pound of steak, giving an excessively acid ash, caused no changes in 3 out of 4 subjects, although there was a slight temporary reduction in plasma bicarbonate in one instance.

These interesting experiments, as well as others, indicate that the daily administration of 45 gm. of sodium bicarbonate is necessary in order to raise the pH of the blood by even 0.2 and that 15 to 20 gm. of ammonium chloride are required to lower the pH of the blood by a similar amount. In order to accomplish the same results by means of food, 18 lb. of oranges would be required in the diet at one time to bring about a shift of the blood toward greater alkalinity, and 4½ lb. of lean beef, or 2 lb. of oysters, the most acid of all foods, would be necessary to produce an effect comparable to that caused by the ingestion of 15 gm. of ammonium chloride.

It is obvious, therefore, that foods consumed in the usual quantities will not alter the acid base balance of the normal person. The explanation for this phenomenon lies in the fact that the human machine is a compensatory mechanism that remains remarkably stable under different conditions. This steady state, called "homeostasis" by Cannon,[3] is maintained by means of various delicate defense mechanisms of the body.

The first and foremost of these defense mechanisms is the buffer action of the blood itself. The important proteins of the blood, hemoglobin and oxyhemoglobin, together with the blood chloride and alkaline phosphates and bicarbonate, react with the carbonic acid of the blood to establish a more or less constant equilibrium. This balance is further aided by the lungs as they dispose of carbon dioxide, the decomposition product of carbonic acid. The lung is consequently the second defense mechanism in the control of the acid base balance.[4]

The third of these body defense mechanisms is the kidney, which unlike the blood, may show a relatively wide range of acidity and alkalinity, varying in extreme instances from pH 5 to pH 8. Excessive quantities of fixed acid or alkali are eliminated through the urine, but this fine adjustment may fail in the presence of certain diseases of the kidney, so that acidosis or alkalosis may occur.

True acidosis is a symptom rather than a disease. The word is, however, a favorite one with food charlatans, who prate of the dire results from certain food combinations. Acidosis is also a popular term with the more gullible of the laity, who invariably confuse this condition with gastric hyperacidity, or so-called "acid stomach," which is due to an excess of hydrochloric acid in that much abused organ.

The accumulation in the body of an excess of acid, or the loss from the body of alkali, occurs as a rule only in certain severe ailments in which there are disturbances of metabolic processes or organic derangements. In addition to nephritis and other kidney troubles, acidosis may accompany diabetes or the diabetic coma, severe diarrhea, starvation, and acute infections, such as pneumonia and sepsis. Acidosis is apparently more common in young infants than in adults, especially in connection with infantile diarrhea, vomiting, and dehydration but, according to Paterson, acidosis or ketosis by itself

leads to little or no change in the clinical picture of the sufferer.[5]

In many clinical reports, the term "ketosis" is used interchangeably with acidosis. Although acidosis may be associated with a ketogenic, or high fat, low carbohydrate diet, ketosis itself is a condition in which there is an accumulation of ketone bodies in the blood as the result of an incomplete combustion or aberrant oxidation of the fatty acids provided by the diet. This condition, usually expressed in terms of the acetone present, is not in itself acidosis. The ketogenic diet is now used in the treatment of epilepsy, migraine, and certain other maladies.

The scientific evidence indicates, therefore, that the question of acid and alkali forming foods is a negligible problem in human dietetics. "It is still an open question," wrote Sherman (in 1932), "whether the acid base balance of the mineral elements of the diet is or is not of practical significance in human nutrition."[6] Evidence showing the relative unimportance of the effects of acid ash and alkaline ash foods has been ably summarized in the Report of the Committee on Nutritional Problems of the American Public Health Association for 1935–1936.[7]

Despite this evidence, food fakirs continue to exploit the alleged dangers of acid foods, and rant over the chimerical hazards of incompatibility in foods. One widely publicized system of diet is based on the erroneous theory that proteins and starches, and fruits and starches should not be mixed in any one meal. As a reason for this perverted idea, it is declared that protein digestion takes place in the acid contents of the stomach, while starch can be digested only in the alkaline intestine, and that carbohydrates encounter some sort of baleful interference when associated with protein in the stomach.

The fallacy of this weird notion will be readily apparent to anyone possessing even a rudimentary knowledge of physiology, but the fallacy has also been exposed in a number of recent scientific experiments. Thus, Rehfuss has shown from gastric analyses of 50 individuals that there is no incompatibility between proteins and carbohydrates in the stomach,[8] and Shay *et al.*, have recently reported, from gastric secretory studies on 5 subjects, that mixtures of protein and carbohydrate not only do not interfere with gastric secretion, but that carbohydrate digestion in the stomach is actually prolonged and encouraged by its mixture with protein.[9]

As pointed out by Rose,[10] an avid public gloats in a belief in magic as applied to human nutrition. Food fads fostered by quacks and ignoramuses, some of whom can claim "M.D." degrees, are espoused and religiously followed by a host of deluded persons. It is the duty of public health officials, as the logical educators of the public in sensible hygiene, to aid in debunking fads and follies, such as the belief that acidosis results from acid foods, and that foods of different chemical compositions can upset the acid base balance of any normal person.

SUMMARY

Although foods may be classed as (1) acid forming, (2) alkali forming, or (3) potentially neutral, there is no scientific evidence to indicate that any one food or combination of foods can significantly alter the acid base balance in a normal individual.

Acidosis is a symptom in certain morbid conditions, but the nature of the diet plays no appreciable part in the development of acidosis, despite the fallacious arguments of food charlatans who exploit unscientific systems of dietetics predicated on excessive acid

forming foods, or on the incompatibility of various food elements.

Upper Potomac River District

. . . Provisions were made by the 1935 General Assembly for the creation of the Upper Potomac River Commission for the purpose of conserving, regulating, and controlling water resources within the Upper Potomac River District, as discussed in the 1934 report. The act defines the boundaries of the district and delegates to the Commission certain powers and privileges, and provides for the government of the District by the Commission.

The Commission is authorized to acquire by purchase or condemnation lands, structures, or buildings, or any stream bed, water way, road way, rights of way, watershed or water rights within the District, for the construction, expansion, or maintenance of any dam, reservoir, or appurtenances thereof; to provide for the construction, maintenance, and operation of structures, buildings, dams, impounding reservoirs, and appurtenances; to provide for the regulation of the flow of water within the district and its tributaries; to provide for the levy of taxes by the County Commissioners of Allegany County for the operation, maintenance, regulation, and control of works purchased, acquired, or constructed under the provisions of this Act; to authorize the County Commissioners of Allegany County to submit to the voters of said County the advisability of making a capital expenditure of not exceeding $200,000 in furthering the purposes of this Act, and, in case of a favorable vote thereon, to borrow or sell bonds up to that amount and turn the proceeds thereof over to the Upper Potomac River Commission; to secure benefits of an Act of the Congress of the United States of America approved June 16, 1933, known as the National Industrial Recovery Act, and any Acts amendatory thereof, and any Acts supplemental thereto and revisions thereof, and any further Act or Acts of the Congress of the United States of America to encourage public works, to reduce unemployment and thereby to assist in the National Recovery and to promote the public welfare, or to regulate the flow of navigable or other streams, to conserve water resources and to provide for the penalties for violation of the provisions of this Act.

The Commission is composed of 3 members; 1 appointed by the County Commissioners of Garrett County, and 1 by the County Commissioners of Allegany County, and the 3rd named by the Governor.

The territory included within Allegany County and Election District No. 4 of Garrett County constitutes the Upper Potomac River District for the purposes of the Act.—*Annual Report of the Bureau of Sanitary Engineering of the Maryland State Board of Health—Year 1935.*

History of Typhus Fever in Louisiana*

E. HAROLD HINMAN, Ph.D.

Department of Tropical Medicine, Louisiana State University Medical Center, New Orleans, La.

THE destruction wrought by epidemics of typhus in past centuries is familiar to everyone. Wherever there has been concentration of the population in close quarters, this pestilence has been rampant. It has devastated armies, jails, immigrant and slave ships, and the population of large cities, especially in times of famine. The various names given to this plague suggest its epidemiology, *e.g.*, famine fever, jail distemper, ship fever, and putrid fever. Other synonyms have been given according to the appearance of the exanthema, as the German Fleckfieber (spotted fever); flea bite fever (because of the similarity of the eruption to flea bites); the Spanish called it Tabardillo; the Italians, Petecchii; and the French, La Pourpé. The word typhus comes from the Greek, meaning stupor.

Vaughan (1915) points out that Hippocrates describes a case very suggestive of typhus but it was not accurately distinguished until the 16th century when Fracastor and also Cardan differentiated it from plague. Typhoid was not differentiated until 1837, by Gerhard, a Philadelphia physician. Vaughan also states that during the 16th century, typhus was so prevalent in the jails of England that it spread among court officers when the prisoners were brought before them for trial. This happened repeatedly and gave the designation of "black assizes" to the court session. The great plague of London (1665), according to this author, was preceded, accompanied, and followed by typhus. At this time the most eminent medical men confused typhus and plague. Typhus fever was apparently introduced into Mexico at the time of the Conquest (1530), and has been endemic there ever since. It was not until 1909 that Nicolle demonstrated that the disease could be transmitted by body lice from monkey to monkey, and this laid the foundation for prophylaxis and control of the infection. The etiology of the disease is still uncertain, but it is generally conceded to be due to *Rickettsia prowazeki* described by Da Rocha Lima in 1916.

TYPHUS IN AMERICA

Kantor (1915) points out that the United States is exposed to infection with typhus on 3 sides, from Asia, from Europe and Africa, and from Mexico. Probably a few scattered epidemics have been introduced from Mexico as, for example, among the New Mexico Indians and in New Orleans from the disbanded troops, but the great majority of cases had their origin in im-

* Presented before the New Orleans Acadamy of Sciences, March 15, 1935, as part of a symposium of the History of Some Important Tropical Diseases in Louisiana.

migrant boats from Europe. Previous to the Civil War typhus was prevalent in all the leading seaport towns of the United States, but is generally considered not to have become endemic. According to Vaughan (1915) the records of the Civil War report 1,723 cases with 572 deaths, but he questions the diagnosis. No cases were reported by Confederate officers.

EPIDEMIC TYPHUS IN LOUISIANA

Data on typhus in early Louisiana is surprisingly scanty. In a diary kept by Dr. McGuire at Monroe, La., from 1818 to 1852 (a typewritten copy is in the Howard Memorial Library), there are a number of entries in the years 1819, 1827, 1832, and 1851, referring to typhus or typhus-like fevers. The syndrome is not described and, owing to the inland location of this town, it is improbable that he was dealing with true typhus. Heustis (1817), an army surgeon, in his *Physical Observations and Medical Tracts and Researches on the Topography and Diseases of Louisiana* makes no reference to epidemics which are recognizable as typhus.

The reports of the Board of Administrators of the Charity Hospital at New Orleans for the year 1832 lists 29 admissions with 17 deaths from typhus fever and 4 additional cases with 4 deaths from congestive typhus fever. Since Gerhard did not differentiate typhoid until 1837, one must accept these records with reservations. The reports for 1843 give 9 cases of typhus, for the year 1844, 4 more, 3 of which were fatal. In 1847 the first real epidemic was recognized when 1,045 cases out of a total of 11,945 admissions occurred. For 6 consecutive years, an average of over 1,200 cases were diagnosed annually in this hospital. Table I shows the monthly distribution of cases or deaths from typhus in the Charity Hospital (1843–1852).

The distribution by months suggests that the infection was introduced in February, 1847, failed to become endemic, but that new cases were imported in October of that year. This epidemic then persisted for 6 or 7 years, during which time typhus might be considered to have become endemic, although new cases may have been frequently introduced.

The *Report of the Board of Administrators of the Charity Hospital* for the years 1848 and 1849 states:

> Cases of smallpox and ship fever must be expected to occur more frequently year by year; the admission of them into the hos-

pital endangers many valuable lives of the officers, physicians, nurses, and attendants, besides those of the patients, among whom an epidemic may be engendered. It is most earnestly and respectfully recommended to the Legislature to make provision against this evil.

It was suggested that the state take over the Franklin Infirmary so as to provide adequate care for typhus patients and thus segregate them from the Charity Hospital patients.

In the early volumes of the *New Orleans Medical and Surgical Journal,* under editorials written on the health and mortality of the city, appear a few casual references to typhus. It is difficult to understand this lack of interest in a disease which accounted for more than 8 per cent of all the admissions to Charity Hospital during this time, unless it can be explained by the attention focused upon the epidemics of yellow fever and cholera raging at the time, yellow fever causing 2,306 deaths in 1847, and 7,849 in 1853, while cholera caused 924 in 1848, 2,081 in 1849, 1,080 in 1852, and 554 in 1853. Thus in January, 1845, the editor writes:

In the hospital there have been a few cases of typhus fever in persons recently arrived by sea, and from the country, but as far as we know, none have originated in the city.

In July, 1847, the editor refers to inmates of the Charity Hospital having contracted ship fever while in the institution. Four employees of the hospital were sick, on the service of Dr. T. M. Logan, with ship fever and 1 died. An editorial in March, 1852, states:

Typhus fever still prevails in the large hospitals and but for the constant accessions to that disease from abroad, we feel convinced that the fever could do us but little harm, and would excite less attention.

Again in May, 1853, the Journal remarks:

Our mortality from fever has been uncommonly small, chiefly attributable, perhaps, to the fact that very little ship fever has been brought in by the emigrants from Europe.

Axson, President of the State Board of Health, in his report for 1859, writes:

It will be remembered that the institution of quarantine was resorted to as part only of a system of preventive measures by which it was ardently hoped the scourge of yellow fever, together with ship fever and cholera, might be excluded from our state. The ravages occasioned not only in our city but throughout the length and breadth of the state by the introduction of the famine fever, more popularly known as the ship fever, of 1847, and of cholera, of 1848, through the instrumentality of the perishing population of Ireland, France and Germany fleeing from the disaster of famine and its invariable attendant, pestilence, were sorely felt in those years. . . .

Ship typhus fever in New Orleans was derived from the European emigrants, especially those from Ireland, who are miserably poor and dirty and arrive with typhus generated on the voyage. On the 11th of February (1848?) 500 cases of ship fever were in the crowded wards of the Charity Hospital. . . . Our city during that and succeeding years was the great thoroughfare of disbanded Mexican soldiers, returning here, worn in health and body and mind; many of them bringing in their persons the infection of the dreaded *vomito* among the other maladies which consumed their life or impaired their health.

Table II presents a summary of available statistics on typhus in New Orleans and in the Charity Hospital compiled from the *Reports of the Board of Administrators of Charity Hospital* and from the *Reports of the Board of Health of the State of Louisiana.*

As a supplement to Table I we may now examine the mortuary records of the City of New Orleans as available in the *Annual Reports of the State Board of Health.* This is contained in Table III.

Jones, President of the State Board of Health, presents a summary from the *Report of the Board of Health of the State of Louisiana* for the year 1883 which is reported in Table IV.

Jones, in commenting on these statistics, says:

Surely, this is a remarkable fact. Truly the prevalence of typhus fever during the 18 years preceding our Civil War, and almost total absence in the 16 years following the great civil convulsion, can be referred to well known causes. First, typhus fever was imported into New Orleans by means of the emigrant ships which bore to these hospitable shores the fever and famine stricken and oppressed inhabitants of Ireland. Previous

to the year 1847, typhus fever does not appear to have made any serious lodgment in the City of New Orleans, although it has been committing ravages in Europe for centuries before.

The disease introduced in 1847, both from Mexico (by the United States troops) and from Europe from the fever stricken and starving districts of Ireland, raged as an epidemic in this city for several years.

The same author points out that although nearly 1,500 inhabitants of New Orleans died of typhus, the disease was confined chiefly to the poor and ill fed, as the majority of the deaths occurred in the wards of the Charity Hospital. He stresses the fact that quarantine is essential to the protection of New Orleans from the introduction of typhus fever and that these measures must be perpetual. He believes that typhus introduced into New Orleans tends gradually to become extinct, due to the better food, better living or ventilation of the mass of the inhabitants. He attributes the improvement in the health of the population partially to the building of an extensive street railroad system which has scattered the dwellings, thus preventing overcrowding.

DISCUSSION

It is unfortunate that no data is available upon typhus fever in Louisiana previous to 1843, with the exception of the *Report of the Board of Administrators of Charity Hospital* for 1832. This latter record is undoubtedly open to question. It is almost inconceivable that typhus was not introduced into New Orleans earlier than this date, when epidemics were so frequent in Europe. The source of the earliest cases in New Orleans has been rightly attributed to immigrant boats from Europe and to the disbanded United States soldiers returning from Mexico. It is very surprising that typhus, once introduced into this city, did not spread throughout the state, but no records of this occurrence exist, with the possible exception of the diary of Dr. McGuire, referred to above. With the introduction of epidemic typhus to New Orleans in 1847, it remained endemic at least through the year 1852, and more or less continuously through 1856, if one judges from the mortuary reports of the City of New Orleans. Following this the infection was sporadic. With the blockade of the city during the Civil War the disease probably disappeared only to be reintroduced upon the occupation by the federal troops in 1862. When foreign trade was resumed a few new cases were admitted, but no epidemic was engendered. Thus throughout the late 60's, 70's and early 80's, we find annually a few deaths from typhus in New Orleans. The writer is unable to explain the almost complete absence of reports of cases from the Charity Hospital records for this period.

Dyer (1933), in discussing typhus, states:

> On its introduction into New Orleans in 1847, the disease was limited to the immigrants themselves and to the doctors and nurses caring for them. This lack of spread of the disease in New Orleans is most readily explainable by the scarcity or absence of body lice in our southern lowlands.

The abundance of lice during these early days is a matter upon which the writer is unable to find any information, but certainly these ectoparasites are not absent today.

One of the peculiarities of the racial distribution of this infection is pointed out by Hoffman, who found that of 502 deaths occurring between 1849 and 1885, only 25 were among the colored. The records of case admissions to the Charity Hospital also speak for the low rate among Negroes.

ENDEMIC TYPHUS IN LOUISIANA

While endemic typhus (Brill's disease?) has been recognized for years in certain southern states, the first case

was reported from Louisiana in 1929 (Rucker). Since then 46 cases have been diagnosed. According to Badger (1934) this is essentially an urban disease with the greatest incidence in the seaports and having a tendency to spread inland along lines of communication. Maxcy (1926) pointed out that epidemiological evidence was against louse transmission and suggested that a reservoir exists other than in man—probably in rodents—from which the disease is occasionally transmitted to man. This has been substantiated by the researches of the U. S. Public Health Service, notably Dyer, Rumreich, Badger and Ceder. Strains of typhus have been isolated from rats in various localities and rat fleas have been found naturally and experimentally infected. Shelmire and Dove (1931) believe that the tropical rat mite, *Liponyssus bacoti*, was responsible for transmission of the infection in Texas.

Two other theories of the epidemiology of Brill's disease should be mentioned. Kantor (1915) suggested that the infection might result from the introduction into this country (upon immune carriers) of lice harboring attenuated typhus organisms. Zinsser (1934), in studying the nativity of victims of Brill's disease in New York and Boston, found that out of 502 cases, 93.6 per cent were born in endemic typhus regions of Europe, and 80 per cent in Russia alone. He concludes that the only assumption compatible with the data is that cases of Brill's disease which have occurred in New York and Boston are recrudescences of typhus fever acquired at an earlier time in endemic typhus foci in Europe. He maintains that Brill's disease is an imported form of the classical European typhus fever. According to this author, the endemic typhus of the northeastern states is distinct from that of southern United States, the latter resembling tabardillo of Mexico.

With these opposing views in mind, the writer studied the histories of 17 cases occurring in Charity Hospital, and the epidemiological reports of the State Board of Health (46 cases). Table V shows the distribution by years and parishes of endemic typhus in Louisiana. The greatest number of cases occur in the rice growing district of the state. With the exception of Orleans Parish, the disease is practically confined to this region. The epidemiological significance of this remains unknown, but might suggest association with rats.

Table VI presents a summary of 17 cases occurring in the Charity Hospital at New Orleans. All of these were white persons and only 3 were females. Twelve were from Orleans Parish. The occupation gives no clue to the epi-

demiology. One case (No. 13) is of doubtful diagnosis. There were no fatalities. Practically all gave a history of fever for several days previous to admission, and progress notes indicate that some of them were not acutely ill. It is quite probable that there are many cases throughout the state which go undiagnosed. The Weil-Felix reaction was positive in all but 3 cases, but frequently was not positive until several days after admission. The monthly distribution did not appear significant. Through the courtesy of the State Board of Health, the writer was able to examine the histories of approximately 30 cases. The occupation of these patients gave no clues except the possible association of some with rats through the rice industry. There was no indication that imported Mexican laborers or other nationalities were responsible for the outbreak of the disease.

DISCUSSION

Endemic typhus was not recognized in Louisiana until 1929, but since that time 46 cases have been diagnosed. While 3 deaths have occurred, many of the cases might be regarded as rather mild and thus, unless the exanthem is observed by the physician the diagnosis would be difficult. No information exists as to the method of transmission, but the geographical distribution suggests possible contact with rats. Whether the rat flea or the rat mite is responsible remains unknown. Certainly the data from Louisiana lend no support to the theory of Kantor (1915) and would indicate that southern endemic typhus must be separated from the Brill's disease of Boston and New York, since none of these cases had contact with Old World typhus.

SUMMARY

Epidemic typhus apparently made its first serious inroads upon the population of New Orleans in 1847 and remained endemic for at least the next 6 years. The pestilence was introduced by immigrant boats from Europe (chiefly Ireland) and probably also by disbanded soldiers from Mexico. That the disease failed to penetrate inland is difficult to explain. It seems to have been confined chiefly to the poorer classes, although hospital attendants contracted it. For the 15 years following the Civil War, only 102 deaths occurred in New Orleans from typhus

in contrast to 1,301 deaths in the 19 years preceding the war. Endemic typhus was first recognized in Louisiana in 1929, and since then, 46 cases with 3 deaths, have been reported in the epidemiological statistics of the State Board of Health. These cases were chiefly from 2 parishes, Calcasieu and Orleans.

Promotion of Human Health

THOUGH nature is sensational in her results, she is not sensational in her processes. In preventive medicine we seek to understand the moves which lead up to dramatic events, but the processes are far from dramatic. In the promotion of human health we gain little or nothing by the treatment of disease, for at the best this is merely a palliative. It can never be very successful even in its avowed object of restoring health to those who have lost it, because what we call disease is in reality not disease itself, but its end product. This does not refer to those acute diseases which are self-limited reactions. Here, improvements in treatment will do much to keep them within the bounds of physiology, so that they neither kill nor permanently damage us. But for those diseases which are not self-limited, for the results of long continued adverse factors which produce structural alterations of a permanent character, or which call for mechanical interference to preserve life, the future can give us little more than the past.—Dunstan Brewer, D.P.H., *Ann. Rep., Medical Officer of Health for the Year 1935*, Borough of Swindon, p. 7.

The Rural Health Conservation Contest as a Factor in Rural Health Development

CARL E. BUCK, Dr.P.H., F.A.P.H.A.

Field Director, American Public Health Association, New York, N. Y.

THE first whole-time county health department was established in 1908. Since that time the county or health district plan has come to be recognized as the most suitable method of organization for health administration in rural areas. This type of rural health administration has gradually developed until there are today approximately 540 whole-time county or district health units in this country.

In spite of the fact that during the past quarter of a century there has been definite progress in rural health work, at the present time less than one-quarter of the rural population is served by full-time local health units. Also on the discouraging side of the picture is the fact that many of these full-time units are not adequately staffed and financed to carry on even a reasonably comprehensive public health program. A considerable number of counties that were originally organized as so-called three piece units (that is, units with a full-time health officer, a public health nurse, and a sanitary inspector), still remain three piece units today. While it is encouraging to observe how well the basic principle of a county or a district as the unit for rural health administration is being accepted, it is discouraging to find so few rural health units which have gone beyond the establishment of the very minimum requirements essential for health services.

Lack of financial support is an obvious and often valid reason for failure to develop beyond the point of minimum staff. It likewise seems certain that in many rural areas most of the people have no understanding of the need or value of more adequate health services. Further development of rural public health work in this country would seem to depend upon recognition and furtherance of two essential principles:

1. That state and federal financial aid is essential for many county or rural districts.
2. That our rural areas need enlightenment on public health requirements and values.

The development of more adequate rural public health services is of vital concern to the people of the United States. This is indicated by the fact that rural death rates in general exceed urban rates, notwithstanding the natural advantages of country life.

The need for greater development of rural health work, together with the success of the City Health Conservation Contest as a precedent, led to the inauguration of the first Rural Health Contest in 1934. The Chamber of Commerce of the United States and the

American Public Health Association sponsored this project, made possible by a grant from the W. K. Kellogg Foundation. The purpose of the Contest is to develop basically sound and more adequate public health services in rural areas.

The first essential step in developing a sound and adequate public health program is to take careful inventory of the community's present facilities and needs. All counties participating in the Rural Health Contest appraise their health activities by preparing a Fact-Finding Schedule which covers minimum basic essential health services. While participation in the Rural Contest is of assistance to all rural health units, it is particularly beneficial to those units in which public opinion has not as yet been sufficiently aroused to make the most effective use of its present health facilities or to seek more adequate services. In preparation of the Fact-Finding Schedule the activities of all groups and organizations are taken into consideration. By this method the attention of local groups is effectively focused upon:

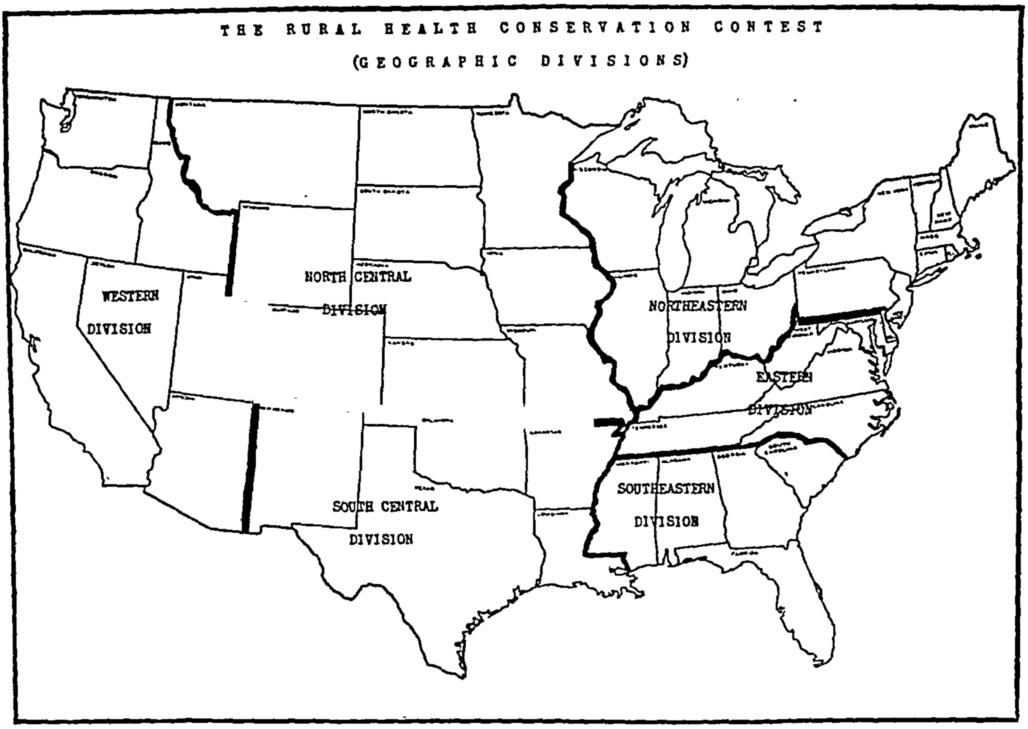
1. The need for effective coördination of the specific health activities which are known to form the basis of the local program.
2. The development of those community resources which have not been effectively and fully utilized, or which have not adequately been brought to light.

The Fact-Finding Schedule when completely filled out presents a report of the community's entire public health program. These reports are submitted to a Grading Committee on or before March 15 of each year and are carefully studied and analyzed. A detailed analysis of each Fact-Finding Schedule is forwarded to each participating community.

In the compilation and consideration of activities as they affect the broad public health program, the need for effective coördination becomes apparent. In addition to activities undertaken as specific health projects, there are in every community groups of individuals who have no connection with health organizations but whose effect upon the community public health can and ought to be of tremendous value. The importance of making the most effective use of such groups as private physicians, dentists, nurses, teachers, nutritionists, parents, ministers, and newspaper editors cannot be overemphasized. A truly comprehensive public health program will never be reached without giving such groups the opportunity of fully participating in the program. For successful participation in the Contest, and therefore for the successful development of a well-balanced, comprehensive public health program, every county or district health officer should consider whether or not he has given these groups the opportunity of developing their potentialities in promoting public health. It is such a community public health program, carefully planned so as to make the most effective use of all the community's resources, including these all important groups, that the Rural Contest seeks to stimulate and encourage.

Although the competitive aspect of the Contest unquestionably tends to stimulate and sustain interest, it is primarily a project designed to encourage the development of sound rural public health work. Full-time field service is provided to contact state and county district health units in the furtherance of this objective. State departments of health have been uniformly enthusiastic and coöperative.

During the first year of the Contest, all counties or districts having full-time health service with local chambers of commerce or similar business organizations affiliated with the Chamber of Commerce of the United States were eligible for participation. Of the



present 540 full-time county or district health units in the United States, only 200 were eligible by virtue of having local business organizations affiliated with the National Chamber. Of these, over one-half, 105, enrolled, and 69, or 65.7 per cent, submitted schedules for grading.

During the second year of the Contest the basis of eligibility was changed to permit a full-time district or county health unit which did not have a chamber of commerce affiliated with the National Chamber, to be sponsored by a local chamber of commerce in an adjoining or neighboring county. This year, the eligibility requirements were broadened still further, to permit full-time units without any suitable local business organization, to enter the contest through direct enrollment with the American Public Health Association, provided a representative public health committee is appointed to sponsor the Contest. All full-time rural health units are now afforded the benefits of participation. Entries in the second year's Contest includes 160 units. Unlike the City Contest which is conducted for various population groups, the rural competition is carried on in 6 geographic divisions of the country. Each county or district health unit competes only with other health units in its own geographic area.

The map indicates the geographic division of the country for purposes of the Rural Contest.

The winning unit in each geographic area is awarded a bronze plaque and certificates of honorable mention are presented to the higher ranking counties.

An article on county health department expenditures and personnel will be published in a subsequent issue of the *Journal*.

PULMONARY TUBERCULOSIS DUE TO BOVINE TUBERCLE BACILLI

FROM time to time we have published editorials on the transmission of bovine tuberculosis to human beings. That such infection takes place was definitely proved at the University of Pennsylvania in 1902. The reports of the British Royal Commission and of the German Imperial Commission amply confirmed the findings, and since that time no one has seriously questioned the danger to human beings, especially children, of tuberculosis in cattle. The vehicle of transmission is, in the vast majority of cases, milk. We have more or less complacently accepted the fact that the bovine type of organism is transmissible to human beings, and that it is prone to produce lesions of the glands and bones, but not the pulmonary disease known generally as consumption. There have been many articles arguing for the relative unimportance of bovine infection, and the National Tuberculosis Association decided not to engage in that phase of the tuberculosis problem.

Our complacency in this regard has been considerably ruffled by the reports of pulmonary tuberculosis due to the bovine organism. From February, 1931, to July, 1933, the State Serum Institute of Copenhagen found the bovine type of organism in 26 patients suffering from pulmonary tuberculosis. During approximately the same period, the bovine type was found in 39 specimens of pus from the cervical glands, in the cerebral spinal fluid, and urine taken from the residents of Copenhagen. All of these patients were under 32 years of age and 10 under 5. In only one case was open tuberculosis found in another occupant of the patient's home. The writers of the report state that, so far from pulmonary tuberculosis due to the bovine type being rare, it is, as a matter of fact, extremely common.[1]

In Amsterdam,[2] in an examination of 115 adults suffering from pulmonary

tuberculosis, 3 gave the bovine organism, and in the province of North Holland, 10 out of 89 such cases also gave the bovine organism. Gastric lavage of 110 children yielded the bovine organism in 9. Examination of material from other forms of tuberculosis gave 55 human type and 11 bovine, but this latter finding is not pertinent to the present discussion. Griffith and Smith,[3] on the basis of extensive investigation in the north-east and southern counties of Scotland, make the statement that pulmonary tuberculosis is frequently caused by the bovine type of organism. From April, 1934, to December, 1935, these authors investigated 103 cases of pulmonary tuberculosis, in 13 of which the bovine type of organism was cultivated from the sputum. In 5 of these, there was a history of previous glandular tuberculosis so that the channel of entry was almost certainly the alimentary canal.

America appears to have fallen behind in this investigation. As far as we are aware, there is no laboratory in the United States doing systematic typing of cases of pulmonary tuberculosis. It is a tedious and expensive piece of work which can be undertaken only by well financed organizations, but that should be no bar to the investigation. It is not too much to say that we have no idea at the present time how many cases of pulmonary tuberculosis are occurring from infection with the bovine type of bacillus. We believe that we are in a better position as regards bovine tuberculosis than other countries, due to the activities of our Bureau of Animal Industry, but this does not excuse our lack of interest and activity in regard to the particular question under discussion.

Very recently the editor has been repeatedly urged to take the matter up and do all within his power to bring about such studies as are being made in England and some of the Scandinavian countries. This is due to a situation in some of our states so serious as to excite apprehension.

As an actual fact, we do not know what is going on, and this of itself is sufficient reason for undertaking the study.

TRAINING OF PROTOZOOLOGISTS

THE training of medical protozoölogists in the United States in the past, with few exceptions, has been neglected.

The recent epidemic of amebic dysentery in Chicago, endemic malaria in the South, the frequent occurrence of trichomonas and trypanosomes in man and animals, and other tropical and semi-tropical protozoal diseases of man and animals necessitate well trained medical protozoölogists, who not only will be able to diagnose and teach, but who also will be engaged actively in research in advancing this branch of science.

Why has the training of protozoölogists in the past been so neglected?—In many of the American universities there is not a single professorial chair in medical protozoölogy. Most medical students acquire superficial and hurried information and occasionally a few demonstrations of pathogenic protozoa in the departments of bacteriology, public health, or clinical medicine.

The divisions of protozoölogy in departments of zoölogy of our universities, on the other hand, deliberately omit medical protozoölogy because of lack of proper facilities and knowledge of aseptic technic and experimental immunology.

Method of training of medical protozoölogists—The introduction of a brief, compact, and well thought out course of medical protozoölogy, preferably in some department of a medical school with daily instruction of from 4 to 8 weeks, probably will be sufficient to cover the subject. The requirements of entrance for such a course, however, should be high, and no student without knowledge of bacteriology, immunology, and histology should be permitted to take the course.

The departments of bacteriology, public health, clinical medicine, or tropical medicine could readily organize such courses, if necessary, by adding a trained protozoölogist to their staff.

The object of the course should be:

1. To give all necessary training to properly qualified students in the form of lectures, demonstrations, and actual laboratory work. The training should be general and should include representatives of all protozoal diseases of man, supplemented with protozoal diseases of animals. Students should also receive sufficient training to be able to identify non-pathogenic protozoa. Special stress should be placed on the etiology, epidemiology, pathology, symptomatology, diagnosis, prognosis, prophylaxis and treatment of protozoal diseases, and the morphological, cultural, and immunological relationship of the different species of protozoa.
2. To broaden the average student's conception of the many forms of protozoa and their activities.
3. To train for original research either under supervision or independently.
4. To train to teach courses of medical protozoölogy and to supervise research when appropriations go into these enterprises.

The teaching of medical protozoölogy has become a burden of the departments of bacteriology, public health, and immunology. The universities that were fortunate in having men in these departments interested actively in protozoölogy, as a rule gave effective training to medical students.

At the University of Michigan, Professor F. G. Novy, as early as 1903, introduced brief and effective lectures on protozoölogy to medical students in the class of bacteriology and intensive training and research to a few graduate students. He continued this until 1934, the last year of his active teaching.

It is hoped that the time is not far distant when in some of our best medical schools chairs or departments of medical protozoölogy will be established.

At present, specific training and information in medical protozoölogy may be obtained, among others, from the following institutions: Harvard University, Department of Tropical Medicine and Department of Comparative Pathology; University of Chicago, Department of Bacteriology and Hygiene; Johns Hopkins University, School of Hygiene and Public Health; Tulane University, Department of Tropical Medicine; Vanderbilt University; University of Michigan; University of California; U. S. Army Medical School; U. S. Naval Medical School; and the National Institute of Health, U. S. Public Health Service.

Medical protozoölogy is a broad subject, indeed, and many of its fields have not been explored as yet. With careful training of more protozoölogists, and with sufficient appropriations for research, this branch of science is bound to grow. Its future is rich with the allurement of interest and in possible benefit to mankind.

SIXTY-FIFTH ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

IT is no empty formality nor specious courtesy to say that the meeting in New Orleans will go down as one of the best we have ever held. The registration has exceeded our expectations—nearly 1700. The welcome has been as warm as the weather. Both state and city officials have exerted themselves to show every courtesy possible, and the well known hospitality of this charming old city has come to its finest flower in welcoming the American Public Health Association and its guests.

New Orleans has a model Auditorium, ample for all possible demands. There are several halls for large meetings, and an abundance of committee rooms for smaller groups. There is abundant space for the largest possible number of exhibits which can be collected, with good lighting and acoustics.

The first general session was held in the huge Concert Hall of the Auditorium. We were welcomed by both state and city officials in the most delightful terms, so much so that everyone desired to accept the invitation of the state officer of health to remain until we went broke.

At this meeting Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, was installed as President, taking over the office held by Dr. Walter Brown. His address was received with deserved enthusiasm, and our readers have it before them in the present issue of the *Journal.*

In the absence of the chairman of the Sedgwick Memorial Committee, the President announced the award of the medal for 1936 to General Frederick F. Russell. This will be given further notice in another column.

Of the many delightful features which have marked the meeting, perhaps none is more noteworthy than the dinner on Tuesday night inaugurated by the Southern Branch of our Association, who invited the Western Branch to participate. This we hope is the inauguration of a most delightful custom. Certainly everyone appreciated it. More than 200 attended. The address of the evening was given by Dr. Allen W. Freeman, Dean of the School of Public Health of Johns Hopkins University, who very gracefully took the occasion to commemorate the services of southern men in the public health movement. We hope that each year will see a repetition of this function.

Space does not permit of a description of all of the functions which have been held by affiliated and associated organizations. Among these were the dinner of the Association of Women in Public Health, the luncheon of Delta Omega, meetings of the Harvard University Alumni, the Yale Alumni, Johns Hopkins Alumni, Massachusetts Institute of Technology Alumni, and the International Society of Medical Health Officers. There were also a number of scientific meetings of associated organizations, such as the American Association of School Physicians, the Association of State Registration Executives, Conference of State Laboratory Directors, Conference of State Sanitary Engineers, National Committee of Health Council Executives, State Directors of Public Health Nursing and Instructors in Public Health Nursing.

Of the constituent nations, Canada gave us the largest delegation. Fourteen members came, and Dr. S. Boucher, the honored Health Officer of Montreal, brought his three charming daughters. Our sister republic on the south was represented by Dr. Angel de La Garza Brito. With the opening of the wonderful

highway between the United States and Mexico City, we are fired with an increased desire to visit that beautiful city and the charming country of which it is the capital.

Cuba was represented by Mr. Carlos Martin and Dr. Domingo F. Ramos.

Among our guests we must mention Dr. Cicely D. Williams, West Africa; Dr. Frank S. Boudreau, League of Nations; Dr. Otto Neurath, Holland; Dr. Charles N. Leach, China; Mrs. Mary K. Cauthorne, Alaska; Dr. Abraham J. Levy, Palestine, and C. F. Blackler, Bermuda.

There were some 41 scientific exhibits, many of which had some feature which in the opinion of the judges was commendable. Certificates of merit were awarded to The American Red Cross, National Society for the Prevention of Blindness, Sewerage and Water Board of New Orleans, and the Committee on Administrative Practice, Health Conservation Contests.

The entertainments provided for the ladies were abundant and arranged by Mrs. Charles F. Buck, Jr., to whom we offer our grateful appreciation. The Ball arranged by the Chairman of the Entertainment Committee, Dr. A. E. Fossier, was delightfully in the spirit of old New Orleans, with its tableaux in carnival costumes, its Negro chorus and Negro street boys. A very large audience assembled and remained until the orchestra played " Good Night, Ladies."

As usual the annual banquet of the Association was a brilliant affair largely attended. The address was given by Dr. Henry E. Sigerist, Johns Hopkins University. Announcement was made of winners in the scientific exhibits.

Altogether the New Orleans meeting will long dwell in the memories of those who were fortunate enough to attend. Our only regret is that owing to our rules made necessary by the great extent of our country, it will be at least 12 years before we can again enjoy the gracious hospitality of this beautiful and historical southern city.

Paratyphoid Vaccines
Feemster, Wetterlow, and *Cianciarulo*

PUBLIC HEALTH EDUCATION*

Institutional Coöperation with the Press—The public relations problems of the hospital, the clinic, the sanatorium in the smaller community rests largely upon the superintendent or other executive as reviewed in "Selling the Small Community Hospital," by J. M. Beeler, M.D., superintendent of Spartanburg (S. C.) General Hospital.

Dr. Beeler discusses the need for community understanding, and how inter-hospital relations with the trustees and the lay auxiliary may be handled to advantage. Particularly important is "Coöperating With the Press."

Usually from our point of view the problem is the newspapers. They usually print much about what we do not want printed and little about the things we desire the public to know. We must remember, however, that we have an entirely different viewpoint. We feel that anything private is not news and the papers feel that everything concerning anyone in the community is news. We should have a common meeting ground and by our trying to understand their viewpoint obtain a better understanding on their part of our problems. I have found that if you are willing to coöperate with the newspapers they will in turn see your situation. They are in position to inform the public of your work, your plans, and to educate the people and establish confidence in what you are trying to accomplish. We must remember that the plans we have and the program we are planning must be news and of interest to our local community. We should remember that . . . when we refuse to take them (newspaper men) into our confidence they are apt to resent our attitude and refuse to coöperate with us. We must also remember that the institution belongs to the community, and the only way they can check on us is through the local papers.

There are certain hospital happenings which are always news and should be given to the press, such as: staff meetings, auxiliary meetings, emergencies, accidents, and illness of prominent people. The hospital may not feel free to discuss certain illnesses and accidents with the papers but the papers should be given the name of the physician and of the patient's family, so that they may obtain further information if the people desire to give it. In other words, coöperate with local papers, they are your mouth piece through which you can educate your community; and remember most papers are working for the same end that you are—the improvement of the community. . . .

In the same issue of *Hospitals*, American Hospital Assn., 18 E. Division St., Chicago, Ill. (Sept., 1936), is "Establishing Friendly Relations." A hospital executive systematically calls briefly upon patients; a friendly follow-up letter is sent to former patients; the business office humanizes the relations; and a hostess meets visitors in the lobby.

What is the result? Our hospital has become boosted widely, indirectly through our efforts, of course, but actually by the unconscious "pushing" of our work by our own ex-patients and their business, social, and family associates. It is the finest sort of publicity and it brings concrete award.

It has often been said, and with reason, that one's experience in a hospital is, for a considerable time afterwards, the most frequent conversational subject. What we have done is to capitalize on this phenomenon, always bearing in mind that the whole process would break down and react unfavorably against us if the "whispering campaign" was ever given a just cause to knock, not boost. . . .

Many public and private health agencies might well take to heart the conclusions of the author:

There is no claim to originality in all this, and to many it may not even be unusual; nevertheless I am convinced that a well con-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

ceived plan for establishing friendly relationships with our patients, their visitors, the ministers, the contributor, the city administration, the staff, and the community at large will, in more ways than one, pay handsome dividends, and eventually gather a host of friends and boosters for the hospital, the value of which cannot be overestimated.

"A Simple Visual Method of Presenting Pertinent Data from the Hospital's Annual Report," Dr. C. G. Parnell of Rochester General Hospital, emphasizes the need of making annual report statistics easily grasped by "the board of trustees, the medical staff, and others concerned in the progress of the institution."

In order to present in an easily understandable form the salient data from the annual report, we have employed for several years in the Rochester General Hospital a very simple series of diagrammatic charts which at a glance will show the data of the current year in comparison with those of several previous years. The diagrams may be presented in the form of printed charts or on lantern slides, the latter method being preferable for presentation to any large group. The mimeographed charts have been found very useful in dealing with budget committees of the hospital and the Community Chest and with government officials and others responsible for provision for hospitalization of public charges.

The vertical block method is used for the diagrams. Other methods may be employed, but this seems to be the most readily understood and easily grasped. Charted curves are not as appropriate for this type of diagrammatic presentation. . . .

How Honest Can We Be?—Enthusiasm for a "good cause" sometimes brings a strain on ideals of honest dealing with the public. Dr. P. B. Brooks, Deputy State Commissioner of Health says:

Public health propaganda at times reflects something of the tendency, so common and apparent in much of the present-day commercial advertising, to exaggerate, overemphasize, and even distort facts in order to attract attention, make an impression, or carry a point. Sometimes the exaggeration is more or less unconscious and unintentional, the result of excess of enthusiasm. In another case it will be readily admitted and an attempt made to justify it on the ground that it is in a good cause.

Perhaps an attempt is being made to persuade an official body to undertake a certain project "in the interest of public health." The dangers of delay or failure to act are vividly pictured. Only those authorities are quoted and figures cited which are favorable to the project. Are there equally competent authorities who advocate some other procedure or data which suggest that a similar project elsewhere has failed? They are not mentioned. The project may be undertaken and be as successful as its advocates have predicted. On the other hand, enthusiasm is likely ultimately to be dampened by the almost certain discovery that the sponsors have been in some measure misled and action taken under a misapprehension. The project has "gone over" but the reputation of the original advocates will suffer. When they come later with a new project their arguments will be taken "with a grain of salt."

It is said of Abraham Lincoln that, in laying a case before a jury, he began by presenting and discussing all of his opponent's probable arguments. Thus he reduced the effectiveness of his adversary's arguments and created an impression of honesty and fairness. . . .

In *Health News*, State Dept. of Health, Albany, N. Y. Aug. 24, 1936. When are health workers in danger of being dishonest?

"He and She, Not It"—Under this title P. D. Hugon tells how to personalize amateur movies.

Turning every "it" into a "he" or a "she" is, in brief, the dominant idea back of all dramatization—cinematographic, literary, or commercial. In a good photoplay, as in a good novel or a well conceived publicity stunt, there are no pure things or ideas; there are only persons, because it is only through personality that most people are able to reason back to abstractions. This obvious principle is commonly overlooked by highly educated people; hence their scenarios, their books, and their advertising alike tend to be dry and boring. The life story of Pasteur will reach millions who would not look at a text on biology. . . .

Here is a dentist who makes better plates. Will he show on the screen the manufacture and fitting of his dentures to a number of

patients? No! He will tell the story of a woman whose happiness was ruined by ugly or missing teeth (or of a man who was handicapped by the same cause). He will show, by way of contrast, a charming young person unattainable by her suitor because of his physical defect. Then he will briefly remedy the trouble and let the romance or the career bloom to a satisfactory conclusion. That is reducing the situation to an over-simple formula, of course; yet that formula is as basic as fondant to candy making. The flavoring can be varied in a thousand ways, but the foundation always must be substantially the same. . . .

Here is a social agency that wants to induce the mothers of babies to bring them to a free clinic. Mere views of the plant, the nurses, and the doctors may remove certain misunderstandings as to what goes on inside the walls, but these things will have little emotional appeal. Let the simple story be told of an ailing child contrasted with a healthy one, followed through a life of misery or happiness, and every mother in the audience will do the figuring for herself. . . .

In *Movie Makers,* 420 Lexington Ave., New York, Aug., 1936. *25 cents.*

Indirect But Graphic Presentation—Straight argument against a fallacy in many cases is not nearly so telling as a graphic, though indirect refutation.

Under "Vitamin Promotion" in *Journal of American Medical Assn.* (Aug. 22, 1936), we find the following:

. . . A new product is a so-called Vitamin Energy Bar, which is claimed to be the equivalent of 3 loaves of bread in fat, 1 lb. of butter in protein, 2½ lb. of cheese in carbohydrates, 2 bunches of celery in calories, 2 oranges in calcium, 1 large egg in phosphorus, and 4 quarts of buttermilk in iron. Somehow the promoter overlooked vitamins F and H as well as zinc, manganese, and copper. This is a fine example of the fallacy of equivalents as a standard of measurement. Instead of giving the equivalent in fat of the butter, the bread is chosen as the example; instead of giving the equivalent of the milk for calcium, oranges are chosen for that comparison. And the calories are said to equal those of 2 bunches of celery. Whoever picked celery for calories! Actually the "Vitamin Energy Bar" seems to provide ½ oz. of fat, ⅙ oz. of protein, and less than 2 oz. of carbohydrate, with traces of calcium, phosphorus, and iron. Those are the facts—but they do not sound nearly as impressive as the great quantities of food represented by the advertiser's equivalents. If however you really want to see if one "Vitamin Energy Bar" is the equivalent of all that food, eat the "energy bar" at one meal and all the food at another. Your digestive system will solve the problem for you—and not mathematically!

NEW

A new outlet for pictures and other types of graphic material is *Mid-Week Pictorial,* 148 E. 47th St., New York, N. Y. Long published by *New York Times,* now as an independent pictorial it will be developed for a large place in the news weekly field. We hope that some carefully selected photographs and other graphic material will reach the editor. Better first get a copy for *10 cents.*

BOOKS AND REPORTS

Physician, Pastor and Patient: Problems in Pastoral Medicine—*By George W. Jacoby, M.D. New York: Hoeber*, 1936. 390 pp. Price, $3.50.

We have read this book with unusual pleasure, and believe that it is one which can be thoroughly recommended, especially to clergymen. There can be no question that every clergyman should know a good deal of medicine and physiology. Many of them show some interest in the subjects here discussed, but few have the necessary training to appreciate the problems presented.

The author writes entertainingly on the origins of medicine and of religion. Sketches of a number of religions and their effects on patients' faith and the general attitude of the adherents to medicine, are given.

Among the vital problems in which the physician and the clergyman are concerned are birth control, suicide, mismating and divorce, criminality, sex education, feeblemindedness, euthanasia, etc. Concerning divorce and mismating, he makes what seems to us a very strong point, in emphasizing the importance of careful selection in marriage rather than divorce, which he calls the undoing of a wrong. A chapter is given to "Modern Religion in Daily Life," in which what it is doing in medicine, hygiene, and social betterment is discussed. An excellent bibliography is given at the end.

There is nothing new in the book. Its value consists in the collection of a lot of material which is scattered through various journals and books on the special subjects considered here. There are a number of excellent illustrations. The whole book strikes us as being a sane discussion of the problems which affect physicians and clergymen alike, and on which they should get together more than they have done in the past. The printing and make-up are excellent. MAZŸCK P. RAVENEL

Principles and Practice of Recreational Therapy for the Mentally Ill —*By John Eisele Davis, B.A., M.A., in collaboration with Dr. William Rush Dunton, Jr. New York: Barnes*, 1936. 206 pp. Price, $3.00.

This textbook is an important contribution not only to the special field of physical education and recreation but also to educators and many others in public health, hospital, or related rehabilitative service.

The Scientific Book Club of New York includes it on its list of scientific books. It has been copyrighted in England. Dr. Matz, Director of Research of the Veterans' Administration, refers to it as a much needed textbook, and Dr. Adolf Meyer has not only written the foreword but has also said that it is a "helpful guide." This brief review merely records with grateful appreciation the real contribution it makes to an ever increasing hospital need.

On page 112, Mr. Davis writes particularly of the regressed patient and of the importance of stimulating the "interest field" and of the re-creation of orderly associations and coöperative relationship. This is one of the strongest points of the entire treatise on "Interest and Effort."

In the somewhat extended experience of the writer with mental patients in

large state hospitals, there has been found to be a fundamental necessity of having patients participate in any physical exercise that will assist in normal physical functioning. This point is vital. It is hoped that Mr. Davis may be able to observe and write about the physical training and recreational activities which are carried on in hospitals where neither age nor sex will have an influence on the findings but will thus have a bearing on regressed states for both men and women.

There have been control situations in Veterans' Facility hospitals that do not exist in other large hospitals, such as sex and age among patients, and nearly always there are well trained assistants. In state institutions it is often necessary to take on as assistants in physical training and recreation employees who have shown interest in the development of such a division of hospital service but who have not had any formal education or training for the work; and who have no knowledge of the educational and understanding technics of psychology, though they have a sympathetic attitude toward the mentally sick that is highly desirable. After such employees understand in particular that every effort must be made to replace sordid, unhealthy, and filthy habits by helping to create a new situation and to awaken interest in life, they frequently give most valuable assistance in the work, and kindly, friendly encouragement to the patients. Such workers may not understand "Practical Teaching Principles" but they can render more helpful service to patients by studying carefully "Formal and Informal Exercises" (Chapter V).

One very strong feature of this book of great value to institutions, is the consideration given to nurses and attendants, as untrained workers, who are assigned to work in recreation or physical training, and programs for their instruction are presented. Inability to plan ahead the sequence of events—either exercises or games—is due to the great lack of training and practice in theory. The author recognizes that any work of this character is under medical direction, and the responsibility of coöperating with the authorities in the matter. Ways and means by which a progressive program may be organized are pointed out.

There are analytical studies and charts worthy of serious attention, but, best of all, are the suggestions for future study presented in several section.

The efforts of the joint authors have certainly met with success in that the text is written in a concise manner, emphasizing throughout the deep interest held in the proper practice of "Recreational Therapy."

ELEANOR C. SLAGLE

The Thyroid: Surgery, Syndromes, Treatment—*By E. P. Sloan, M.D. Springfield, Ill.: Thomas,* 1936. 376 pp. Price, $10.00.

If a word of apology is needed for publishing in a public health journal a review of a book devoted largely to surgery, it may be found in the preface, in which the author stresses the preventive aspect, expresses his hope that what he has written will be of interest to the public health official, and says flat-footedly that control of thyroid disease is the province of preventive medicine, which, properly applied, will save immeasurably more lives than the surgeon's art can. It is unusual as well as refreshing to find a book in which the preventive side is so well presented along with competent treatment.

The discussion from the endrocrine standpoint is good, and the handling of pre-operative treatment, operative technic, and post-operative management is excellent. A criticism one is

inclined to make is that there is apparently lack of sufficient discussion of the question of metabolism as it relates to the thyroid problem. It is true that a general discussion which covers the ground fairly well is given, but it might be elaborated to make it of more use to the average man. There is a splendid chapter on the thymus.

The author expresses himself in an unusually clear and instructive fashion. The illustrations are exceptionally good. The printing and make-up of the book are what we have come to expect from the publisher. DUDLEY A. ROBNETT

Workers' Nutrition and Social Policy—*International Labour Office (League of Nations). Geneva. London: P. S. King and Son,* 1936. 249 pp. Price, cloth $2.50, paper $1.50.

A survey of data on the diets of workers in Europe and North America leads to the conclusion that large numbers of the industrial population are inadequately nourished. Such malnourishment and under-nourishment occur not only in impoverished and depressed areas, but in the most advanced industrial countries in times of normal business activity.

The cause of this condition is stated to be chiefly an economic one, although ignorance and ineffective use of available income are factors, as is also the non-use of the potential capacity of agriculture. The solution of the problem lies in research and education, social legislation leading to improved purchasing power, and international cooperation.

Although the data given in this bulletin on actual consumption of foods by workers are somewhat limited, the report contains much valuable and provocative material, which should be of especial interest to sociologists and nutritionists. There are able discussions of dietary standards and the nutritional needs of workers in various occupations. The social-economic aspects of the problem are likewise set forth in considerable detail.

Copies of this well printed report can be obtained in this country from the World Peace Foundation, 8 West 40th St., New York, N. Y. JAMES A. TOBEY

Your Child in Health and in Sickness—*By Hugh L. Dwyer, M.D. New York: Knopf,* 1936. 333 pp. Price, $2.75.

This is a convenient and practical handbook on child care from the standpoint of modern preventive pediatrics. It is written with the intelligent mother in mind. The text is readily comprehended and appropriately illustrated.

Each step that should be taken in raising the child from infancy to adolescence is considered. Results of scientific research of foods, immunities, and child guidance are incorporated. The material is singularly free from fads or fancies and should prove of considerable value in guiding young mothers in sensible methods of preserving and promoting the health of their children. RICHARD A. BOLT

Medical Aspects of Crime—*By W. Norwood East. Philadelphia: Blakiston,* 1936. 437 pp. Price, $6.50.

The author of this book writes from a background of 36 years of experience as Prison Medical Officer, Medical Inspector of Prisons, Prison Commissioner, and head of the Prison Medical Service of England and Wales. In the first 4 chapters he reviews the prison administration problems in England for the past two centuries and devotes considerable time to a historical résumé of conditions of English prisons in the early 18th century up to the present date. He makes comments relative to changes in the laws of prisons, the changes in the attitude of the general public toward crime and prisoners, and finally compares the physical welfare of

the present English prisoner with that of the early 18th century prisoner. The entire book is composed of lectures and papers which he has written and published in book form with special chapters devoted to attempted suicide, observations on exhibitionism, relationship of the skull and brain to crime, relationship of cellular imprisonment to detention in association, mental inefficiency and adolescent crime, suicide from the medical-legal aspect, mental defectiveness with alcohol and drug addiction, medical aspects of prison labor, mental aspects of crime, mental problems connected with the prosecution of offenders, sterilization, prison reaction types, psychological medicine, and criminal law.

In these various papers and lectures Dr. East has successfully evaluated the various problems of modern penal administration from the medical viewpoint and has injected a large amount of common sense in giving his personal opinions relative to some of the more modern ideas in the realm of criminology. He speaks from practical experience and with a mind apparently open to the many researches that have been made in this field, and his deductions are the product of the same experienced prison administrator. His analysis of 1,000 consecutive cases of attempted suicide, which is a criminal offense in England and punishable by 2 years' imprisonment, is very interesting. He reviews the literature of phrenology and the findings of such well known authors as Lombroso, Goring, McDougall, and others, and states that the students of criminology today have discarded phrenological speculations and have turned to psychology, the science of behavior, for an explanation of anti-social conduct.

In discussing the prison reaction types he speaks of 6 types: depressive reaction, impulsive reaction, hysterical reaction, paranoid reaction, mental deterioration, and malingering, and discusses each type. He feels that simple sterilization of criminals is of little eugenic value but more thought and research should be given to castration as a method of treatment of sex offenders in an effort to have them make a sex readjustment.

This book should be of great interest to all students of criminology, prison administrators, prison medical officers, and those interested in forensic psychiatry. He decries the ultra sympathetic approach to the problems of criminals which is frequently prevalent in the field of psychology.

P. C. ROBERTSON

The Growth and Distribution of Population—*By S. Vere Pearson, M.D. (Cambridge), M.R.C.P. (London). New York: Wiley,* 1935. 448 pp., 20 ill. Price, $4.00.

The author of this sociological work is physician to the Mundesley Sanatorium, Norfolk, England.

Information respecting the author's background, in addition to that suggested by the titles of his recent papers, may be found in the Preface where he states:

> An understanding of the problems connected with the growth and distribution of population requires a knowledge of economics and psychology, two sciences which I have studied for more than thirty years. I do not refer so much to the economics and psychology of the textbooks as to the elementary common-sense forms, a knowledge of which an average man or woman acquires from life's experience and from nowhere else. These require neither instruments nor laboratories.

As a consequence of this postulate the author states that he reached conclusions that "differ in many particulars from the conclusions arrived at by those who write on the subject of population."

The 23 chapters deal with a wide variety of subjects embracing climate, agriculture, property, law, government,

growth of cities, sanitation, vital statistics, love, town and country planning, ground values and property appraisals, "traffic troubles," housing, and emigration. The book is based essentially on the principles set down by Henry George and his followers. When these principles are generally accepted human geography, the author believes, will enter a new era.

The author displays an easy facility for disposing of the work of distinguished scientists in remarks pregnant with opinion. Moreover, these remarks, among others, are too frequently terminated with a gratuitous exclamation point. In referring to Raymond Pearl's fly experiments, which formed a chapter in his work on population growth, the author remarks, "Pearl's years of labour are sterile. Flies in bottles are really unlike assemblages of human beings!" Statements based on opinion are not limited to the author's references to scientists. For example, in a discussion of contraception he writes that the moral atmosphere of classes and groups in society that use contraceptives is generally low.

In spite of its shortcomings this personal record of a physician's relationship to the world about him is stimulative and deserves to be recommended to those interested in human affairs of the present and future.

The typography of the book is excellent. An adequate index is provided. There is no bibliography.

WILLIAM M. GAFAFER

Eye, Ear, Nose and Throat Manual for Nurses—*By Roy H. Parkinson, M.D. St. Louis: Mosby,* 1936. 232 pp. Price, $2.25.

In bringing his book up to date, Dr. Parkinson has again demonstrated his appreciation of the rapid growth of knowledge needed by our nurses in the care of eye, ear, nose and throat. We are all too prone to lump the whole subject under a few general rules of no specific value for guidance to those outside the profession needing wholesome advice.

This new and revised edition, especially part three, deeply impresses upon our minds not only the distinct necessity of a definite technic for the care of each specialty listed but a fundamental knowledge needed in directing those about us on questions that come up from time to time.

We welcome this book as a worth while asset to our reference library.

L. ELEANOR KEELY

Health Stories, Book Three—*By Anna B. Towse, Florence E. Mathews, and William S. Gray. Chicago, Ill.: Scott, Foresman & Co.,* 1935. 208 pp. Price, $.76.

This is a new book in the Curriculum Foundation Series and is intended for third grade children. Its immediate predecessor was reviewed in these columns some months ago. The current book maintains the same high standards of interest and usefulness.

MERRILL E. CHAMPION

Preventive Medicine—*By Mark F. Boyd, M. D. (5th ed.) Philadelphia: Saunders,* 1936. 561 pp. Price, $4.50

A book which has reached its fifth edition has usually proved its worth. The reviews of this work from the first edition on have been uniformly favorable. It has met with wide use and given general satisfaction.

So many new things come up in bacteriology and preventive medicine that the necessity for frequent editions of a book on either of these subjects is manifest. New material has been included in this edition on colds, ringworm, psittacosis, diphtheria, encephalitis, poliomyelitis, pneumonia, tuberculosis, malaria, typhus, and relapsing fever, making in all an edition of 33 pages.

This edition is well printed and bound and can be recommended as bearing the general excellent character of its precedessors and as being up to date. MAZŸCK P. RAVENEL

Healthful Living—*By Harold S. Diehl, M.D. New York: McGraw-Hill,* 1935. 354 pp. Price, $2.50.

Common sense and balance characterize this helpful book by Dr. Diehl. It is thoroughly scientific in its approach to the major health problems, and modern in its presentation.

The chapters on Stimulants and the Normal Sex Life may be too well balanced for the "last Puritan" on the one hand, or the "released modern" on the other, but at any rate these difficult subjects are presented with clarity and sanity.

The chapter on Exercise-Fatigue-Rest is reassuring to those of us who have felt that while exercise has its place in the health program it cannot accomplish miracles. Dr. Diehl takes issue with the physical culturists who claim that "exercise and diet will prevent everything from neurasthenia to cancer, from baldness to flat feet."

Very practical suggestions are offered on the choice of foods, weight and its control, and digestive disturbances. The results of the latest scientific research are incorporated in the chapters on Specific Disease Prevention and the Glands and Their Internal Secretion.

Dr. Diehl's sympathetic, as well as scientific, handling of the health problems of advancing years gives a poetic flavor to the concluding chapters.

RICHARD A. BOLT

Public Administration—*By John M. Pfiffner, Ph.D. New York: Ronald Press,* 1935. 530 pp. Price, $4.00.

Designed primarily as a textbook for courses in public administration, this volume should prove a useful reference guide for health administrators who desire to familiarize themselves with trends in governmental organization and with practical developments in public management—local, state, and national. References to public health are frequent throughout the text, together with constructive discussions of relationships of various governmental junctions. Defects in administrative methods are considered objectively; and more than one side of a debatable practice or organization plan is presented.

The 24 chapters are arranged under 5 major headings: organization, personnel, financial administration, administrative law, and public relations; the latter, for example, dealing with the public and its servants, reporting to the public, and standards for measuring administrative performance. The advantages and limitations of boards and commissions, the significance of the merit system, budget planning and purchasing are considered in the light of the mature experiences of the author. This volume is further characterized by clarity of presentation of technical details, abundance of helpful references, and good printing.

IRA V. HISCOCK

New Pathways for Children With Cerebral Palsy—*By Gladys Gage Rogers and Leah C. Thomas. New York: Macmillan,* 1935. 167 pp. Price, $2.50.

There are very few books of a practical nature written in English which deal with the education and reëducation of children with spastic paralyses. This book is exceptional in its method of presentation and lucid descriptions. It can be read with profit by parents and teachers as well as by those entrusted with the technical methods of treating the aftermath of cerebral palsy.

The summer camp with a definite and constructive program of activities for these handicapped children is

recommended. In order to stimulate and maintain interest, it is set up along the lines of Robin Hood and his band of merry men. Robin Hood's Barn becomes the center of activity. The authors stress the importance of conscious relaxation for these children and give concrete suggestions to inculcate the health habit.

The chapter on Muscle Training through Indirect Methods is especially helpful. The illustrations of apparatus used add to the value of the book. The possibilities and limitations of surgical treatment of cerebral birth palsies are given briefly in a chapter by Dr. R. Nelson Hart of the Shriner's Hospital in Springfield, Mass.

Part II discusses in a sympathetic manner the responsibilities of the parents, the importance of a case history, and the arrangement of the child's room. The educational aspects are well balanced in the concluding chapter.

RICHARD A. BOLT

The Legal Aspects of Milk Control—*By James A. Tobey. Chicago: International Association of Milk Dealers*, 1936. Price, $3.00.

Copies of this valuable text, which covers such topics as the public control and sanitary regulation of milk, licensing, standards, pasteurization, tuberculin testing, containers, and liability, and has references to more than 300 court decisions, can be ordered through the Book Service of the A.P.H.A.

Health Center Districts, Statistical Reference Data, Five-Year Period, 1929-1933 *(3rd ed.)—Compiled by Godias J. Drolet and Marguerite Prudence Potter; prepared under direction of Kenneth D. Widdemer, Committee on Neighborhood Health Development, Department of Health, New York City*, 1935. 140 pp. Price, $1.00.

The third edition of this useful statistical handbook meets a growing demand on the part of health and social agencies, and other professional groups, for localized vital statistics as a basis for sound program building. The 140 pages contain not only statistical tables, giving basic information concerning population, births, infant and maternal mortality, and important causes of sickness and death by districts for the entire city, but also an enlightening graphic presentation by health areas of characteristics of eight "Sore Spot" districts, or districts where the most difficult health and social conditions exist and where the city's most active district health development has occurred.

The material contained in this handbook and the method of presentation illustrate methods of appraising needs which have heretofore been only partially utilized in health administration. After commenting on the helpful guidance to be derived from such information, the health commissioner makes the following statement regarding health district organization as a means of securing successful health service in a large city:

> Advance in public health depends on a better understanding and a health consciousness on the part of the general public. To attain this an intimate contact between the health agency and the workers and the public is essential. Health work should be emphasized and developed from within small units of population carefully linked with supervision from without. The health center is something that the public can see, feel, and have a part in. Health center activities can be adjusted to meet local conditions and needs. Public health programs have too often failed to make progress because of lack of understanding and team play between health officials, nonofficial agencies and medical groups. Health centers based on friendliness and understanding should help to remedy such situations.

One of the first steps of the Committee on Neighborhood Health De-

velopment, before recommending formal organization of district health centers, as described in the handbook, was to survey the distribution and composition of the population, neighborhood by neighborhood in each of the five boroughs, the existing health and hospital facilities, the size and distribution of the school population, and especially health conditions, mortality and morbidity records in every section. With these data, showing needs, responsibility, and opportunity, practical boundaries for each district were outlined. Recognizing the limitations of statistical data for single years when broken down for small areas, the committee assembled this 5 year experience. The handbook is a valuable contribution, not only as a source of information for workers in New York City, but as a reference book for teachers and students of vital statistics and health administration elsewhere.

IRA V. HISCOCK

The Normal Diet and Healthful Living—*By W. D. Sansum, R. A. Hare, and Ruth Bowden. New York: Macmillan,* 1936. 243 pp. Price, $2.00.

This book is an outgrowth of the custom of the authors for several years to meet daily with groups of patients to discuss subjects, particularly those connected with nutrition. These mutual exchanges of ideas proved of benefit to both patients and the authors. It is aimed to present in simple language the practical application of recent discoveries in this field. "If even a greater part of our present nutritional knowledge . . . were well utilized, not only malnutrition but many common ailments would in a very large measure disappear."

The first 3 chapters of the book deal with essential food substances, their sources, and the purposes they serve. The following chapters deal with the physiology of digestion and a study of metabolism; the elimination of wastes, and discussion of the dangers attending the use of cathartics; discussion of overweight and underweight, their causes and treatment; the influence of diet on growth and development of teeth. "A seemingly irrelevant chapter on focal infection is included to show that certain diseases which many have ascribed to diet are really of bacterial origin, and that a cure must be brought about by removing the bacteria." The closing chapter gives a survey of methods of treatment including brief discussions on rest, dietotherapy, physical treatment, psychotherapy, drugs, vaccines, sera, glandular preparations, surgery, X-ray and radium, nursing. Emphasis is laid on the intelligent use of the many therapeutic agents available, which is necessary for the best interest of the patient. In the appendix are given suggestions on planning the family menu, with sample menus of different types of diets.

This little volume is a valuable contribution in supplying to the public badly needed reliable information based on our present knowledge of health and nutrition. The general public is being increasingly and alarmingly preyed upon by faddists and quacks motivated by personal gain in exploiting their dieting systems, cures, and treatments. Reliable information based on recent discoveries is not easily available to a large proportion of the population. They get only fragments of the facts in advertisements too often distorted and perverted to serve selfish interests. Presentation of accurate information in simple, non-technical language from authoritative sources is the only way to combat this evil successfully. To this end the authors of this book have contributed a real service.

D. BREESE JONES

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

For Better Record Keeping—Recommendations for the standardization of reports of health department services are made by a committee of the State and Territorial Health Officers. All administrators will want to study this.

ANON. Tabulation of Health Department Services. Pub. Health Rep. 51, 36:1236 (Sept. 4), 1936.

Here Is Solid Achievement—How Newark gets practically all its preschool population immunized against diphtheria by everlastingly sticking at it is told in sufficient detail to stimulate others to try to beat the record.

CRASTER, C. V. Diphtheria Control by Immunization. Health Progress (New Jersey Health and Sanitary Association), 3, 4:6 (Sept.), 1936.

Scarlet Fever Prevention Abroad—Warning against the dangers of crowding in isolation wards, this British author favors the isolation of scarlet fever at home. When properly protected, the routine exclusion from school of other children in the family is not warranted, so he holds.

FORREST, A. W. Scarlet Fever Control on Modern Lines. Pub. Health, 49, 12:412 (Sept.), 1936.

Fewer Children Are Burned—Among preschool children burns are the most frequent cause of accidental death, but fortunately the numbers of such deaths show a tendency to decline. Relative rates are broken down in age groups and sections of the country. This is another example of the value of applying statistical methods to safety studies.

GAFAFER, W. M. Some Changes in the Relative Mortality from Accidental Burns among Children in Different Geographical Regions of the United States. 1925–32. Pub. Health Rep. 51, 38:1308 (Sept. 18), 1936.

National Progress and Public Health—Wholesome soul searching invited by one who dares the health worker to look up out of his deep little rut and consider what he is doing in terms of social welfare. A good dose for all to take.

LINDEMAN, E. Social Planning for Tomorrow. Pub. Health Nurs. 28, 9:561 (Sept.), 1936.

Good News for Old-Timers—Viewers-with-alarm are wont to insist that the average age at death has increased only because we save more babies, and that older people die earlier than their grandaddies did, due to the particular pet theory of the alarm-viewer. This life table built upon New York City census findings shows that people past their prime also enjoy an improving expectancy of life.

MALZBERG, B. Life Tables for New York City. New York Dept. of Health Quart. Bull. 4, 3:74 (Aug.), 1936.

Sound Advice for Parents—Entertaining discussion of the inadvisability of stuffing a prescribed diet into children. If allowed to do so, healthy children will select an adequate diet from a well supplied family table.

SWEET, C. Voluntary Food Habits of Normal Children. J.A.M.A. 107, 10:765 (Sept. 5), 1936.

How Long, Oh Lord, How Long?—We can take no pride in our public

health measures, we cannot pretend to be civilized, this author contends, so long as we maintain our present attitude toward venereal diseases. What we should be doing is set forth for all to see and ponder over.

POPENOE, P. The Family and Society. Pub. Health Nurs. 28, 9:567 (Sept.), 1936.

Frontal Attack Upon Syphilis—An unusually fine symposium on the newly emphasized syphilis control program which should be read by all public health administrators:

VONDERLEHR, R. A. The Administration of the Syphilis Control Program.

SMITH, D. C. Practical Epidemiology of Syphilis.

MOORE, J. E. Development of Adequate Treatment Facilities for the Control of Syphilis.

CASSELMAN, A. J. Efficient Laboratory Service in the Syphilis Control Program.

STOKES, J. H. Education of the Physician and the Movement for Venereal Disease Control.

NELSON, N. A. The Civilian Educational Program in the Control of Syphilis. J.A.M.A. 107, 10 and 11:782 (Sept. 5), 1936.

Influenza in the Air—Influenza virus can be recovered after suspension in air for a half hour. Infectivity of the virus for ferrets may be destroyed by ultraviolet radiation.

WELLS, W. F., and BROWN, H. W. Recovery of Influenza Virus Suspended in Air and Its Destruction by Ultraviolet Radiation. Am. J. Hyg. 24, 2:407 (Sept.), 1936.

G. Harold Warnock, M.D., 528 Seward St., Rochester, N. Y., Epidemiologist-in-training, State Dept. of Health

SEDGWICK MEMORIAL MEDAL

AT the New Orleans Annual Meeting, the Sedgwick Memorial Medal, given "for distinguished service in public health," was awarded to Frederick F. Russell, M.D., Lecturer in Preventive Medicine and Public Health in Harvard Medical School and Harvard School of Public Health.

Frederick F. Russell, M.D.

This medal, awarded by a special committee of the American Public Health Association annually, was created in memory of the late William Thompson Sedgwick, Professor in Massachusetts Institute of Technology, and one of the outstanding investigators and teachers in the field of public health.

For 22 years, beginning in 1898, Dr. Russell was a member of the Army Medical Corps, and is now Brigadier General of the M.O.R.C., U. S. Army. He rendered distinguished service in the field of public health by demonstrating for the first time the efficacy of vaccine prevention of typhoid fever among the United States troops mobilized along the Mexican border in 1911 and subsequent years.

In 1920 Dr. Russell became Director of the Public Health Laboratory Service of the International Health Board, Rockefeller Foundation, and later succeeded to the position of General Director of the International Health Board, now the International Health Division of the Foundation, from which he retired in 1935. Since 1924 he has been a member of the Public Health Council of the State of New York. He was awarded the Distinguished Service Medal in 1919. He is a Fellow of the American College of Surgeons, the New York Academy of Medicine, the American Medical Association, the Association of American Physicians, the Royal Medical Society of Budapest, Hungary, and a corresponding member of the Gesellschaft der Aerzte, Vienna, Austria. He became a member of the A.P.H.A. in 1920 and a Charter Fellow in 1922.

NEWS FROM THE FIELD

FRANKWOOD E. WILLIAMS, M.D.

MENTAL health workers mourn the sudden and premature death of Dr. Frankwood E. Williams, for he was one of the country's outstanding leaders in mental hygiene and for many years its foremost spokesman. Dr. Williams received his medical education at the University of Michigan, and immediately after graduation, in 1912, became resident physician at the State Psychopathic Hospital in Ann Arbor, going from there to the Boston Psychopathic Hospital, then serving as Medical Director of the Massachusetts Society for Mental Hygiene. He was Associate Medical Director, and, subsequently, Medical Director of The National Committee for Mental Hygiene, being connected with the committee from 1917 to 1931. He was Vice-Chairman of the National Health Council 1922–1923.

Dr. Williams's 14 years of service with the National Committee were coincident with the period of its greatest growth. During this time the mental hygiene movement made world-wide progress, culminating in the First International Congress on Mental Hygiene held in Washington in 1930 and attended by representatives from 50 countries. Dr. Williams organized the scientific program which was so largely responsible for the success of this notable conference.

Dr. Williams touched the mental hygiene movement at many of its most vital points, helping powerfully to shape its philosophy and direction, and profoundly influencing the thought of all workers in mental health and related fields. The present-day conception of mental health as a broad and inclusive term, meaning not merely freedom from mental disease but the capacity for personal and social adjustment in all its phases, is to no small degree due to his work. To him mental health stood for the expression of human behavior at its best, for the wholesome fulfillment of personality, the ability to attain and maintain satisfactory human relationships. As such it embraces many aspects of life not formerly considered as matters of health and goes beyond "health" in the restricted sense of that term. Hence the influence of mental hygiene upon fields of endeavor outside of public health proper, and the wide scope of its social inferences and applications. In its preventive and positive aspects, Dr. Williams saw that it could not be confined to the psychiatrist, but, being a basic factor in all human affairs, was of vital interest to the general practitioner, pediatrician, nurse, social worker, educator, minister, and others dealing with human problems.

Dr. Williams was a great educator and an effective interpreter of mental hygiene teachings in all their implications. As a lecturer and writer he was much in demand and he contributed widely and deeply to professional and public education in mental hygiene. He edited *Mental Hygiene* the official organ of the mental health movement in this country from its inception in 1917 for 15 years. His untimely death brings to a close, all too soon, a notable and brilliant career.

ETHER DAY

ETHER Day was observed on October 16 at Harvard Medical School. Dr. Paul Dudley White, Assistant Professor of Medicine, delivered the principal address.

ARMY MEDICAL LIBRARY ANNIVERSARY

THERE will be a celebration of the One Hundredth Anniversary of the founding of the Army Medical Library, of Washington, on November 16.

The celebration will be held in the Library building at 8:00 P.M., and more than 1,000 invitations have been issued, approximately half of these to foreign institutions and libraries, and individuals well known in the fields of medical science and in the history of medicine. At the invitation of the Surgeon General of the Army, Sir Humphry Davy Rolleston, Bart., of Haslemere, Surrey, England, has consented to deliver the oration. Sir Humphry was formerly Regius Professor of Physic of the University of Cambridge, and is interested in the history of medicine and particularly in the Army Medical Library, which makes his coming visit of particular interest and significance. The program will include an introduction by the Librarian and an address of welcome by the Surgeon General of the Army, Major General Charles R. Reynolds, to be followed by an examination by the invited guests of the operation of the library with explanations by the staff, and a display of rare books and manuscripts. Following the program refreshments will be served and music will be furnished by the U. S. Army Band. Colonel Harold W. Jones, Medical Corps, the Librarian of the Army Medical Library, is General Chairman of the meeting.

AMERICAN CONGRESS OF PHYSICAL THERAPY

AT the 15th annual convention of the American Congress of Physical Therapy, held in New York, September 7–10, William Bierman, M.D., of Mount Sinai Hospital, New York, was elected President. He succeeds John S. Hibben, M.D., of Pasadena, Calif.

HUMAN GENETICS

THE Bureau of Human Heredity, of London, is collecting material dealing with human genetics.

The Bureau is directed by a Council representing medical and scientific bodies in Great Britain. It is affiliated with the International Human Heredity Committee, which insures coöperation in areas where research is proceeding.

The Council would be grateful to receive all available material from institutions and individuals, furnishing well authenticated data on the transmission of human traits whatever these may be. Pedigrees are particularly desired; twin studies and statistical researches are also relevant.

Material should be given with all available details in regard to source, diagnostic symptoms and the name and address of the person or persons who vouch for accuracy. All such details will be regarded as strictly confidential.

Those wishing for a copy of the Standard International Pedigree symbols may obtain one from the Bureau of Human Heredity, 115 Gower Street, London, W. C. 1, England.

HUGH S. CUMMING

ON January 31, 1936, Dr. Hugh S. Cumming * retired as Surgeon General of the U. S. Public Health Service, a position which he had held from February, 1920, until that date (*A.J.P.H.*, Mar. 2, 1936, p. 312).

In honor of Dr. Cumming, a document has been published giving the speech of the Honorable S. O. Bland, of Virginia, in the House of Representatives (Feb. 24), and letters from President Roosevelt and the Secretary of the Treasury.—*Dr. Hugh S. Cumming, Surgeon General of the U. S. Public Health Service.* Gov. Ptg. Office, Washington, 1936.

* Fellow A.P.H.A.
† Member A.P.H.A.

RAY LYMAN WILBUR COLLECTION ON SOCIAL PROBLEMS

THE Hoover War Library, a part of the Stanford University Library at Palo Alto, Calif., is assembling detailed historical material about the history, objectives, and activities of the various organizations related to the health field.

It is planned to make these materials part of the Ray Lyman Wilbur Collection on Social Problems in the Hoover War Library. This will be a separate unit which contains the files and records of the White House Conference on Child Health and Protection, Better Homes in America, the President's Conference on Home Building and Home Ownership, and an extensive collection on medical economics.

According to Mrs. Inez G. Richardson, who is Curator of the Collection, this information and the materials will be made available for the use of a wide range of students in training for positions of leadership in education and public health.

The American Public Health Association has been invited to submit information regarding its historical origin and its present activities.

SHORTAGE OF PUBLIC HEALTH NURSES

ACCORDING to a special report on health department nursing service, prepared by the Advisory Committee of the National Organization for Public Health Nursing, Boston leads in the 10 largest cities in the country in the number of public health nurses with 45 per 100,000 population, and Chicago is the lowest with 17 per 100,000. The following numbers are given for the other large cities:

Detroit	32 per 100,000
Cleveland	30 per 100,000
Milwaukee	30 per 100,000
Pittsburgh	28 per 100,000
Baltimore	26 per 100,000
St. Louis	22 per 100,000
Philadelphia	19 per 100,000
New York	18 per 100,000

WESTERN SCHOOL OF PUBLIC HEALTH

THE University of California and Stanford University have organized a Western School of Public Health to assist health departments of western states in the training of public health personnel. Social Security funds are used to finance the school. Dr. Karl F. Meyer,* San Francisco, is in charge.

WEST VIRGINIA INDUSTRIAL HYGIENE BUREAU

THE State Department of Health has established a bureau of industrial hygiene financed by federal funds matched by state appropriations, with Dr. Otto J. Swisher, Jr., Berkeley Springs, as director.

NEW LEPROSARIA

A SPECIAL committee of the Philippine Islands Bureau of Health has selected sites for 3 regional treatment stations for lepers in Luzon: Enrile, Cagayan; Bangued, Abra; and Norzagaray, Bulacan. The president of the islands advocates establishment of these stations, believing that it is unwise to segregate all lepers in Culion.

NEW HEALTH UNITS IN RHODE ISLAND

THE State Department of Health has established 3 new district health units in coöperation with the U. S. Public Health Service. Dr. James P. O'Brien, Woonsocket, will be in charge of the north district; Dr. Joseph Castronovo, Providence, the southeast district; and Dr. Raymond F. McAteer,† Peacedale, the south district.

SANITARY OFFICERS' ASSOCIATION

THE name of the New York State Sanitary Officers' Association has been changed to New York Health Officers' Association. Dr. Chalmer J. Longstreet,† Binghamton, is president.

* Fellow A.P.H.A.
† Member A.P.H.A.

NEW MEXICO HEALTH OFFICERS MEETING *

AT the Conference of New Mexico District Health Officers held in Santa Fe on July 10, the following resolution was unanimously adopted and forwarded to the secretary of the New Mexico Pharmaceutical Association:

WHEREAS the prevention of the spread of syphilis depends upon its treatment in the early contagious stage, and
WHEREAS in the 3 years only 2 requests have been made to the state laboratory for diagnostic outfits for use in the early sero-negative stage, and
WHEREAS we have heard evidence that in the early stages many people seek and secure prescriptions from drug stores, and
WHEREAS it is incontrovertible that no treatment secured in this way is of any value for the cure of syphilis or the elimination of contagion, now therefore be it
RESOLVED that this second conference of the New Mexico District Health Officers urge the New Mexico Pharmaceutical Association to take whatever steps it finds practicable to discourage and to prevent the prescription by drug store clerks and pharmacists for the disease of syphilis and that they encourage all pharmacists in the state to urge upon their customers the great importance to themselves as well as to the public health of immediate medical treatment for this disease.

RHODE ISLAND'S NEW DIVISION OF INDUSTRIAL HYGIENE

THE State Department of Health has established a Division of Industrial Hygiene through funds available under the Social Security Act. Dr. James Philip Deery,† Wallum Lake, R. I., is Director.

CRAIG YEISER MEMORIAL FUND

THE University of Cincinnati has received a gift that in 5 years will amount to $55,000 from Mrs. Louise Fleishman Yeiser to establish in the college of medicine the Craig Yeiser Memorial Fund in Preventive Medicine, for research work.

MONTCLAIR HEALTH DEPARTMENT LABORATORY FIRE

ACCORDING to the *New York Times,* a fire of undetermined origin on August 17 caused damage estimated at more than $5,000 in the Health Department Laboratory on the third floor of the Montclair Municipal Building, Montclair, N. J. Valuable laboratory equipment was said to have been destroyed.

ANNUAL REPORT OF ROCKEFELLER FOUNDATION

DURING 1935, the Rockefeller Foundation expended $12,725,439, of which $2,733,050 was for medical science, and $2,200,000 for public health work.

TEXAS INDUSTRIAL HYGIENE DIVISION

THE State Department of Health has created a division of industrial hygiene financed by Social Security funds, with Dr. Carl A. Nau,† formerly Professor of Physiology, University of Oklahoma School of Medicine, as director.

INDUSTRIAL HYGIENE IN VIRGINIA

A NEW Bureau of Industrial Hygiene was established by the State Department of Health in Virginia on July 1, with Dr. William D. Tillson,† of Richmond, in charge. The bureau is financed by Social Security funds.

ERADICATION OF BOVINE TUBERCULOSIS

THE State of Rhode Island has been designated a modified accredited area, signifying the practical eradication of bovine tuberculosis. The recognition of Newport County as a modified accredited area placed all the counties in Rhode Island in that status. The term

* Fellow A.P.H.A.
† Member A.P.H.A.

is used by department and state veterinary officials to designate areas in which there is less than one-half of 1 per cent of tuberculosis among cattle as shown by official testing. All reactors to the tests must also be removed and precautions taken to prevent reinfection of the area.

With Rhode Island, there are now 41 states listed as modified accredited areas, in addition to the District of Columbia.

STUDY OF SILICOSIS

THE New York City Department of Health, Cornell University Medical College, New York Hospital, and the New York Tuberculosis and Health Association are conducting a study of silicosis made possible by an appropriation from the WPA. About 3,000 workers exposed to dust will be examined and some will be admitted to wards of the New York Hospital where intensive bacteriologic, pathologic and clinical studies, will be carried out.

CARY P. MC CORD HEADS DETROIT BUREAU OF INDUSTRIAL HYGIENE

THE Detroit Department of Health recently established a Bureau of Industrial Hygiene and Occupational Disease to coöperate with industry in the elimination of work conditions inimical to workers' health. It will be an advisory rather than a regulatory or law enforcing agency. The department is in charge of Dr. Cary P. McCord,* as Director; William H. Cary, Jr.,* as Sanitary Engineer; W. G. Frederick, as Chief Chemist; and Herbert Walworth, as Engineer for field activities.

PERSONALS

DR. MELVIN E. MCCASKEY, Little Rock, Ark., has been appointed to the State Board of Health to succeed the late Dr. Wells F. Smith, Little Rock.

DR. ROY E. SCHIRMER, formerly of Little Rock, Ark., has been named Director of the Mississippi County Health Unit at Blytheville, succeeding Dr. Arthur M. Washburn.†

DR. JAMES R. SCOTT,* formerly Health Officer of the Third Health District of New Mexico, has resigned from this position to resume teaching at the University of New Mexico, Albuquerque, in the Department of Health Education.

DR. JAMES T. DUNCAN,† Acting Health Commissioner of Wooster, Ohio, has accepted a position as Assistant Epidemiologist with the Virginia State Department of Health at Richmond.

DR. CHARLES J. FISHER, of Moulton, Ala., has been appointed Health Officer of Lawrence County.

DR. WILL M. HOYT, of Hillsboro, Ohio, has been appointed Health Officer of Highland County.

DEATHS

JOHN LEO BURKHART, Big Rapids, Mich., at one time State Health Commissioner, died July 12.

DR. ALEJANDRO RUIZ SOLER, of Puerto Rico, Insular Commissioner of Health from 1917 to 1925, died September 23. He was 50 years old. The first islander to head the Health Department, he assumed charge after passage of the organic act granting American citizenship to Puerto Ricans. Under his direction, the first hospital for tuberculosis cases was established on a 100-acre site near San Juan which he had secured as a gift.

SIR GEORGE SEATON BUCHANAN, whose official work in connection with public health and sanitation has been recognized throughout the world, died October 11, at the age of 67.

---

* Fellow A.P.H.A.
† Member A.P.H.A.

DR. JAMES CLIFFORD PERRY,* of San Francisco, Calif., retired Assistant Surgeon General and Medical Director of the U. S. Public Health Service, died suddenly October 19, at the age of 72. In 1889 he entered the U. S. Public Health Service as an Assistant Surgeon. He became a Surgeon in the Service in 1904, a Senior Surgeon in 1915, Assistant Surgeon General in 1918, and the Service's Medical Director in 1930. Dr. Perry retired from the Public Health Service a few years ago.

Positions Wanted

HEALTH OFFICERS

Physician, M.D. Medical College of Virginia; 3 years in the Medical Corps, U. S. Navy; city health officer for 16 years; desires position as health officer. Eastern city preferred. A-274

Physician, M.D. Hahnemann Medical College; special course in public health at University of North Carolina; wishes position as county health officer in the Northeastern area. Served as school physician of a small township for 7 years. Available at once. A-275

Physician, M.D. University of Wisconsin; M.P.H. Harvard School of Public Health; special courses in industrial hygiene; available now for an administrative position or one in industrial hygiene. A-279

Physician, M.D. New York Medical College and Flower hospital; extension course for public health officer, New York State Department of Health; 3 years' Urologic service in various New York City hospitals; desires position as health officer or in social hygiene department. A-266

Physician, M.D. University of Nebraska; 13 years' experience as city or county health officer in different sections of the West; desires position as health officer. Prefers West Coast. A-267

Physician, M.D. Indiana University; C.P.H. Johns Hopkins University; special courses in epidemiology, bio-statistics and public health administration; several years' experience as physician to city health department; desires position as full-time county health officer. A-269

Physician, M.D. Western Reserve University; 3 months' Health Officers' course at Johns Hopkins; 1 year's experience as instructor of Hygiene and Bacteriology; 4 months as county health officer; desires position as health officer or in the field of research. A-273

M.D. desires position as health officer. Has been city and school physician for four years. A-280

LABORATORY

Young man, M.S. in Bacteriology, University of Colorado, desires position in a health department laboratory or in the teaching field. Experience covers laboratory work in a state health department, graduate assistant in the department of bacteriology and public health of a university school of medicine, and bacteriologist and chemist of a city health department. West preferred. L-276

Young woman, B.S. University of Chicago, desires position in the field of bacteriology or parasitology. Has been employed as first assistant and research fellow in the department of bacteriology, parasitology and serology of a Chicago hospital, head of a private clinical laboratry, supervisor of a unit for survey of food handlers for carriers of E. histolytica under Chicago Board of Health, bacteriologist in a health department and in a tuberculosis sanitarium. L-277

Technician. Position with specialist or group by man having both clinical and laboratory experience with G.U. cases and syphilis. Competent Serologist. Thirteen years' full-time laboratory, all routines. Trained New York Post-graduate, St. Luke's and Massachusetts General. L-278

Young woman, B.S. Tufts College; M.S. University of Illinois; Ph.D. Western Reserve University; 4 years' experience as director of a city health department laboratory and several years' experience in both commercial and hospital laboratories; desires position doing research or routine in chemistry, bio-chemistry, bacteriology or serology in public health laboratory. L-272

Gentleman, with Bachelor of Bacteriology degree, Medical courses at University of Maryland for 4 years, wishes position as bacteriologist with chance to do investigation work, laboratory director or instructor in science and public health. L-281

Young woman, A.B. Barnard College, special courses at Delamar Institute of Public Health, Columbia University, at present Medical student at New York University, wishes part-time work in statistics or in a laboratory. L-282

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

Directory of Health Service

VITAMINS IN CANNED FOODS

V. VITAMIN G

● By 1926, it was apparent that the antineuritic vitamin B of earlier investigators was in reality a combination of several vitamins. In that year, Goldberger postulated the existence of a second vitamin associated with the so-called vitamin B "complex" which he designated as the P-P or pellagra-preventive factor. Evidence has been offered that this factor—subsequently named vitamin G—exerts a specific action in the cure and prevention of human pellagra and a similar condition in experimental animals (1).

Since Goldberger's pronouncement, considerable research has been devoted to resolution of the vitamin B complex and, what is equally important, to testing the specificity of vitamin G in the cure of human pellagra (2).

The findings in the laboratory and clinic have not, in some respects, been entirely in accord (3).

As reports of further investigations appeared in the literature, it became clear that the vitamin B complex had been aptly named. At one time claims were made for the existence of as many as eight factors in this complex (4).

While later work has reduced this number, we know today that what has been considered in the past as vitamin G is, in reality, a combination of several factors. A relation between experimental cataract and vitamin G has been described and, recently, another associated factor was postulated (5).

The significance of these individual factors in human nutrition has not as yet been established. However, regardless of this fact, students of nutrition are agreed that we must provide for the inclusion of so-called vitamin G—admittedly a complex—in the daily dietary. It is also obvious that until more is known about the individual components of the complex, we must continue to depend upon present day bioassay methods to determine the "vitamin G" potencies of foods.

In this connection, many canned foods have been found by comparative studies to retain their original vitamin G potencies as measured by methods now in common use (6).

Investigators in the U. S. Public Health Service have described their values in the control of human pellagra (7).

Commercially canned foods, therefore, may be used with confidence that they will supply amounts of vitamin G consistent with the amounts present in the raw food materials.

AMERICAN CAN COMPANY

230 Park Avenue, New York City

The Serum Disease Rates for

SCARLET FEVER STREPTOCOCCUS ANTITOXIN

GLOBULIN *Lederle* MODIFIED

PROMINENT CLINICIANS of considerable experience in the use of antitoxin in the treatment of scarlet fever collaborated recently with LEDERLE LABORATORIES to accumulate records on the incidence of serum sickness following use of LEDERLE's new Scarlet Fever Streptococcus Antitoxin, Globulin Modified.

A series of 306 cases were reported as having received the SCARLET FEVER STREPTOCOCCUS ANTITOXIN, Globulin Modified. The serum disease rate for all degrees and types was found to be only 12%! Of this total, 7% were mild in character; 3% moderate and 2% severe. In the majority of cases, serum sickness was limited to mild urticarial lesions which quickly disappeared.

The therapeutic dose of SCARLET FEVER STREPTOCOCCUS ANTITOXIN Globulin Modified *Lederle* is less than 4 cc. in volume, as compared with the therapeutic dose of 10 to 15 cc. commonly available before the introduction of "Globulin Modified" antitoxins. This represents an average reduction in bulk of the dosage of 70—80%!

Packages:

1 Prophylactic Dose in syringe (2000 units)
1 Therapeutic Dose in syringe (6000 units)

GAS GANGRENE ANTITOXINS SQUIBB

For prophylaxis

Tetanus Gas Gangrene Antitoxin Combined Squibb

A combination of tetanus, perfringens and vibrion septique antitoxins for *prophylactic* use in any wound where there has been extensive laceration or crushing injury to tissues, puncture wounds or those contaminated with soil, before the diagnosis has been made or the infection has developed. Supplied in syringes and in vials containing: Tetanus antitoxin, 1500 units; Perfringens antitoxin, 2000 units; and Vibrion Septique antitoxin, 2000 units.

For treatment

Gas Gangrene Antitoxin Squibb

A combination of perfringens and vibrion septique antitoxins for *curative* treatment after the infection has been established. Supplied in vials containing: Perfringens antitoxin, 10,000 units; Vibrion Septique antitoxin, 10,000 units.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858.

HOW ABOUT THOSE WHO *Refuse* MILK

Let us face this problem frankly.

Milk is a necessary part of the daily diet but there are a large number of children and adults who drink no milk at all because of taste prejudice.

The important food value of milk is *below the cream line* because milk is one of the best food sources for Calcium — and Calcium is probably the greatest single deficiency in the American diet.

To these "milk refusers," wherever your duties provide an opportunity, you should recommend Krim-Ko Chocolate Flavored Drink.

Krim-Ko is not intended to replace milk in the normal diet—altho an occasional serving of Krim-Ko with its likable chocolate flavor does help prevent taste monotony.

But "milk refusers" *will* drink Krim-Ko, which gives them some butter-fat and all the Calcium and Phosphorus found below the cream line in milk.

Krim-Ko, rich in Calcium, equal to milk in food energy value, is bottled and pasteurized by selected local dairies. It carries the Seal of Acceptance of the Council on Foods of the American Medical Association.

FREE DIET INFORMATION

Everyone concerned with health and food should have the story of the valuable elements found in Krim-Ko Chocolate Flavored Drink. We shall be glad to furnish you complete information about Krim-Ko and its place in the diet—Write today to the Krim-Ko Company, 4830 S. Turner Ave., Chicago, Ill.

KRIM-KO

REG. U.S. PAT. OFF

Krim-ko is chocolate flavored, pasteurized, partially de-fatted milk (added Tapioca-salt)

Progress in Maternal and Child Welfare Under the Social Security Act*

MARTHA M. ELIOT, M.D., F.A.P.H.A.

Assistant Chief, Children's Bureau, U. S. Department of Labor, Washington, D. C.

EIGHT months have elapsed since the passage of the supplemental appropriation act making available funds for grants to states authorized under the Social Security Act of August, 1935. It is appropriate that a report of progress should be given at this time to the Child Hygiene Section of the American Public Health Association with regard to the activities under those parts of the act that have to do with maternal and child health, crippled children, and child welfare, as outlined in the provisions of the first 3 parts of Title V of the act and as administered by the Children's Bureau. The provisions of the act with respect to maternal and child health and services for crippled children I can assume are known to this audience; those that have to do with child welfare are probably less well known and their purpose and scope and the correlation of this program with the other 2 will be referred to briefly.

In all 3 parts of the title preventive services are stressed. The maternal and child health program is entirely a preventive one; in the crippled children's program, though medical and surgical care and hospitalization of crippled children are the chief services rendered, nevertheless, care of children suffering from conditions that may lead to crippling is specifically authorized in the act, and such preventive services are actually being rendered at this time in a number of states, notably in Mississippi, Alabama, and Tennessee, where the recent epidemic of poliomyelitis has occurred. In the child welfare program attention is being directed toward the prevention and amelioration of those social and economic conditions that lead to maladjustment of the individual child in his relation to family and community. The act permits the state public welfare departments in coöperation with the Children's Bureau to make grants to local communities in order to pay part of the cost of services for dependent, neglected, and homeless children, and children in danger of becoming delinquent, with the pur-

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

pose of providing for children living in the rural and semi-rural areas the type of care that has been available for these socially handicapped children in larger cities for many years.

During the past 8 months rapid progress has been made by the states in establishing these 3 programs. On the map in Figure I will be seen the status of each state and territory and the District of Columbia on October 15 of this year. Symbols show whether plans for maternal and child health, for crippled children, or for child welfare services have been submitted to and approved by the Children's Bureau.

During the 5 months ending June 30, plans submitted by 46 states, Hawaii, Alaska, and the District of Columbia for maternal and child health services for the fiscal year 1936 were approved by the Children's Bureau. One additional plan has been approved for 1937 and it now appears that the last of the 51 will very soon be approved.* One state with an approved plan for 1936 has not yet submitted a plan for 1937. The rapidity with which the maternal and child health programs have been developed has been due in no small part to the experience gained by the states as a result of the administration of the Maternity and Infancy Act from 1921 to 1929.

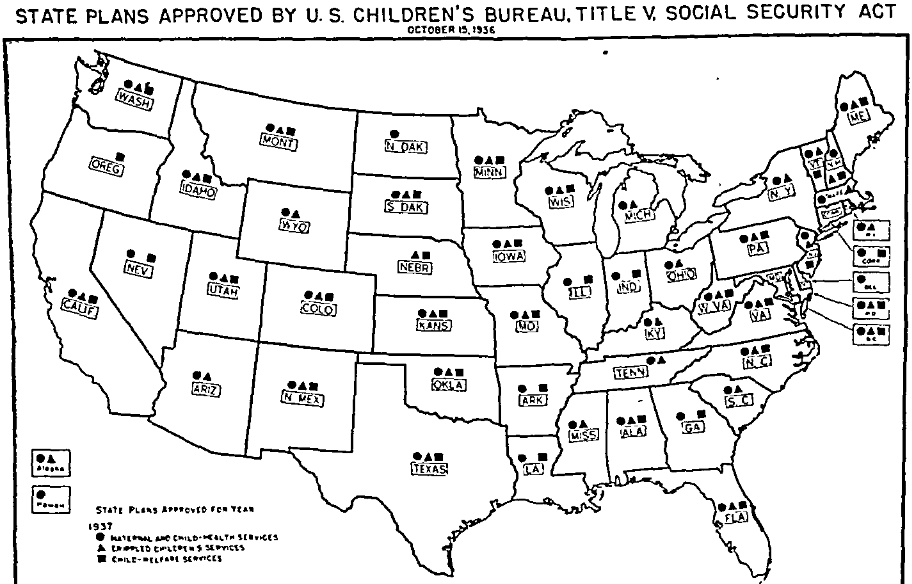
Plans for services for crippled children were submitted by 44 states before June 30 and 38 of these were approved by the Children's Bureau. When approval was withheld, the reason was in all cases one involving the question of the authority of the state agency submitting the plan to assume under the state law final administrative control over all parts of the program as required by the federal act. Since July 1, 2 additional plans have been approved and 4 others are being studied from a legal and administrative point of view to determine whether or not legislative action will be necessary before approval can be given. Seven states have not yet submitted plans. The difficulty in some cases is a question of legal authority; in others one

* Approval has been given to this state's plan since this paper was read.

FIGURE I

STATE PLANS APPROVED BY U. S. CHILDREN'S BUREAU, TITLE V, SOCIAL SECURITY ACT

OCTOBER 15, 1936



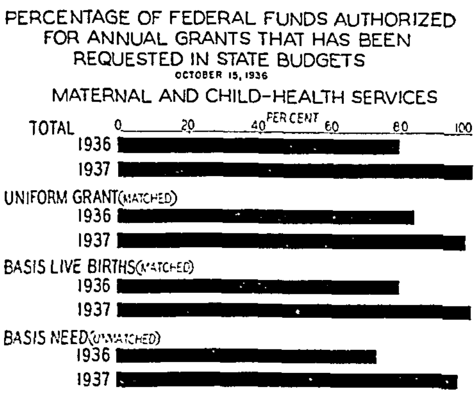
See Notes, p. 1162.

of financial participation by the state.

Plans for child welfare services were submitted by 40 states before June 30, and payments under approved plans were made to 34. Since the beginning of the new fiscal year 7 additional state plans have been approved and 1 other has been submitted and is awaiting approval. In these programs, as in those for crippled children, some states have not had an official agency in a position to coöperate. Inasmuch as the legislature in nearly all states will meet in regular session in 1937, it is expected that practically every state will be coöperating in all 3 programs by the end of the current fiscal year.

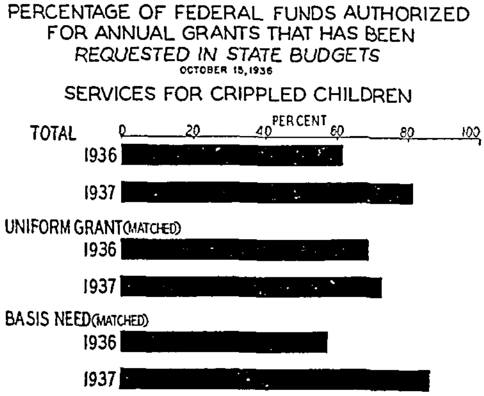
The Social Security Act authorizes annual grants to states for maternal and child health in the amount of $3,800,000; for crippled children in the amount of $2,850,000; and for child welfare in the amount of $1,500,000. Figures II, III, and IV give the proportion of each of these funds that was requested by the states and territories submitting plans for the 5 months ending June 30, 1936, and also for the fiscal year 1937. The total amount for maternal and child health is shown divided into its component parts as outlined in the act, the amount granted as uniform allotments of $20,000 to each state, the amount

FIGURE II



See Notes, p. 1162.

FIGURE III

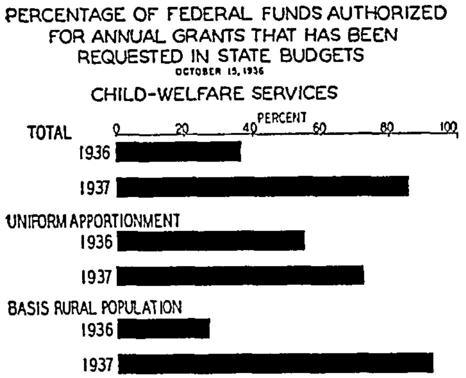


See Notes, p. 1162.

granted on the basis of live births (both of which must be matched by the states), and the amount granted on the basis of the financial need of the states for carrying out their state plans. During the 5 month period ending June 30 plans and programs were in a preliminary stage of development; information with respect to available matching funds was not always complete; the inclination to limit new work until a sound policy of expansion was established was nearly universal. As a result, a smaller proportion of available federal funds was requested for 1936 than has since been requested for the year 1937. That this development should have been relatively slow is, of course, desirable.

Figure III shows the proportion of authorized grants requested by the states in 1936 and 1937 for services to crippled children. Again, the total amount has been divided as outlined in the act, into that granted as uniform allotments of $20,000 to each state and that granted on the basis of the need of the state as shown by the estimated number of crippled children and the cost of care. Here, too, the proposed plans for 1937 call for a larger proportion of available federal funds than did the plans for 1936. Figure IV shows

FIGURE IV



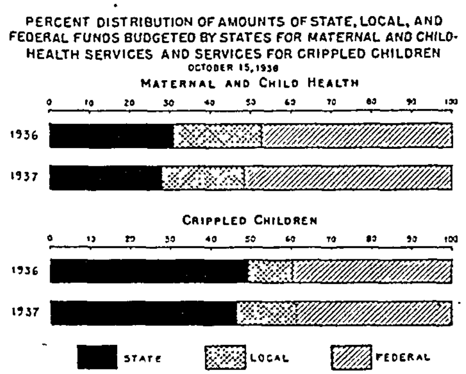
See Notes, p. 1162.

proportion of authorized grants for child welfare services. These also have been divided, one amount being granted as uniform allotments of $10,000 to each state, the other on the basis of rural population. The rapid progress that has been made in establishing this almost wholly new program is evident.

Further analysis of the budgets for maternal and child health and for crippled children submitted by the states to the Children's Bureau for both 1936 and 1937 shows additional facts that are of interest. In each case the budgets submitted give the cost of the total proposed plan and the amounts to be charged to state, local, and federal funds. The per cent distribution of the amounts charged to each of these funds for the fiscal years 1936 and 1937 has been computed for the total group of states coöperating and is shown in Figure V. The large proportion of state funds appropriated for work with crippled children is in marked contrast to that for maternal and child health, and indicates a strong tendency for centralization of the crippled children's program in the state agency. There is, however, some indication that the amount of local participation is increasing. Together state and local funds for crippled children far exceed federal funds. This excess is apparently accounted for by a large excess of state funds in a small number of states where work for crippled children has been highly organized in the past and where state and local appropriations have been substantial over a period of years. It should be pointed out, however, that of the 44 states submitting plans for crippled children, 5 have not appropriated or set aside enough funds in 1937 to match even the uniform grant of $20,000. The increase in the proportion of federal funds budgeted for maternal and child health for 1937 as contrasted with 1936 is due not to a decrease in state and local funds used for matching but to requests for increased allotments from the unmatched fund that is granted on the basis of need of the state to carry out its state plan. Again, 5 states have not appropriated or set aside enough to match the uniform grant of $20,000 for maternal and child health.

More detailed study has been made of the estimated expenditures as budgeted by the states for the 5 months ending June 30, 1936. Of the total amount provided for maternal and child health, nearly 20 per cent was budgeted for the services of physicians, either as full-time administrators or as part-time assistants in health conferences or in postgraduate teaching; 38 per

FIGURE V



cent was budgeted for public health nurses; 5 per cent for dental, nutrition, and health education services; 6 per cent for clerical assistance including some for vital statistics; 16 per cent for travel for state and local staff; and 15 per cent for biological supplies, equipment, printing, and other incidental expenditures. Nearly 80 per cent of the total is being spent for actual service for mothers and children. Apparently federal funds are being used by the states to build up the maternal and child health program by providing full-time physicians to give medical leadership to the program, part-time physicians for conferences and clinics, special consultants and instructors in pediatrics, obstetrics, nutrition, and health education, supervisory public health nurses and many staff public health nurses. Actually half the cost of the services of physicians administering the maternal and child health program and of the specialized public health nursing supervisors was charged by the states to federal funds in the 1936 budgets. An even larger proportion of the expenditures planned for medical, nutrition, and health education specialists, and for instructors in pediatrics and obstetrics is being charged to federal funds, reaching more than 90 per cent in the case of special consultants, instructors, and members of advisory committees. On the other hand, slightly more than half of the cost of dental services and staff nurses, and considerably more than half the cost of clerical services, supplies, and incidental expenditures is being borne by state and local funds. Similar figures for 1937 are not yet available for comparison with 1936.

Study of the detailed budgets for the crippled children's program for the 5 months ending June 30 shows a quite different picture, as would be expected from the terms of the Social Security Act. Funds for state-wide administration and for services of full-time personnel constitute only 11 per cent of the total state, local, and federal funds included in the plans of 38 states; 81 per cent was budgeted for hospitalization, surgical and medical costs, and costs of appliances. Other expenditures, including supplies and equipment and also travel, largely for state staff, made up the remainder. If the provisions of the act that have to do with the establishment of state-wide services for crippled children, and especially those that have to do with after-care are to be carried out adequately, it is likely that there will be increased allotment of funds for administration and field personnel and a proportionate decrease in allotments for surgical services. Obviously, the best operative procedure may be wasted if follow-up care by nurses, physiotherapists, physicians, and social workers is inadequate.

Considering the short time that funds have been available and the nature of the requirements of the act, the progress made by the states in planning and in the administrative aspects of the program has been, on the whole, satisfactory.

But what about actual programs and the progress made in the establishment of new services or the extension of old programs? The Social Security Act requires that maternal and child health services shall be extended to local communities and administered by them. Reports of progress made during the first 5 months of the program were submitted to the Children's Bureau by 47 states in July and August of this year and show some striking evidences of the initiation of new work. In 208 counties, 77 towns, and 11 health districts, new maternal and child health services were put into operation before June 30 and expansion of service was reported from 167 additional counties,

42 towns, and 16 health districts, making a total of 521 local communities with improved maternal and child health service in the first 5 months of the program. Among these have been listed the placement of public health nurses in full-time county health units and in unorganized communities; the organization of maternal, infant, and preschool health conferences and centers under medical and nursing supervision; the institution of maternity nursing services; venereal disease control among pregnant women and children with congenital syphilis; midwife instruction and supervision; nutrition services; school health examinations; immunization programs; and dental hygiene programs. In 20 states plans for the "demonstration services in needy areas and for groups in special need" that are required under the act had reached the point where they could be put into actual operation before June 30; in 4 additional states the programs were ready for operation on July 1.

With respect to the plans for these demonstrations much could be said would time permit. It should be pointed out, however, that maternal care is the major objective of 31 such demonstrations described in the 1937 plans and part of a joint maternal and child health program in 18 others. Plans for the establishment of maternity nursing service at delivery for women living in rural communities have been reported by more than 20 states and in a few the plan includes provision for medical care as well as nursing. It is hoped that through these demonstrations there will be developed methods which are of sufficient practical value that many rural communities will be able to use them or adapt them to special needs. The emphasis that has thus been placed on the need for more adequate and more complete maternity service by physicians and nurses bodes well for improvement in service and the reduction of mortality rates, not only maternal rates, but also neonatal and fetal.

The state plans indicate clearly that improvement in maternity services and in the care of the new-born infant is generally believed to be a matter of professional and lay education, and that the responsibility for effective programs must be borne by clinicians and public health administrators working together. Professional education for physicians and nurses is a part of the proposed maternal and child health program in a majority of the states. The plans include short postgraduate courses or institutes in obstetrics or pediatrics for practising physicians, special postgraduate courses for physicians administering the maternal and child health programs, continuous staff education for public health nurses, and additional training for nurses who are to be specialized supervisors in this field.

The progress reports from the states showed that during the 5 months ending June 30, 13 states inaugurated postgraduate work for physicians in obstetrics and pediatrics, and 8 started postgraduate work for nurses. Altogether during this initial period, 65 nurses, 21 dentists, and 8 physicians received special training in some phase of the program. Coöperation between the state and county health departments and the state and county medical societies in the inauguration and carrying out of the postgraduate courses for physicians is described in all state plans including such courses as part of their program. Furthermore, in all approved state plans there appears evidence of actual coöperative planning by the health authorities with medical, nursing, and welfare groups and organizations, or of proposed coöperative activities to be carried out as the plans progress.

With respect to progress under plans for crippled children, information is somewhat more limited, largely on account of the fact that in many states the program is new and the development of plans necessarily slow. However, some information as to expansion of services is available. Progress can be measured in part by the strengthening of the state administrative staff and the staff needed for state-wide services for locating crippled children and for their after-care, a phase of the work that has been neglected in many programs in the past. During the first 5 months a total of 122 new full-time staff members were appointed by 33 states. This number includes 15 full-time physicians as administrators, 33 orthopedic nurses, 10 physical therapists, 17 social workers, 6 workers described as supervisors, and 41 clerical assistants. Many other such workers are planned for and the positions will be filled as qualified candidates are found. A large number of surgeons or physicians are assisting in the diagnostic clinics and in operative work on a part-time or a fee schedule basis.

Though in many states the period of operation of plans in the last fiscal year was very short, diagnostic clinics were reported to have been held in 7 states where the service is entirely new and from 11 other states reports were received showing expansion of this type of service into a number of the more remote areas not previously reached. Hospital facilities were increased or established for the first time in a number of states; facilities for convalescent care have been increased in only a few so far. Follow-up service and after-care by nurses and social workers is being augmented rapidly, but no figures are available with regard to the scope of these services. An excellent beginning has been made, however, in many states with respect to strengthening the central administrative staff and the field service, and the extent of the coöperative activities carried on by crippled children's agencies with medical organizations and with public health, public welfare, and vocational rehabilitation agencies is most encouraging.

In the program for child welfare, definite progress is being made in all of the states coöperating with the Children's Bureau. In 308 counties or districts (in 4 states districts are composed of several towns), child welfare services have been put into operation with the use of federal funds, supplemented by the localities. Workers attached to the state welfare departments are providing some case work and general child welfare service in 192 additional counties in order to demonstrate the necessity for more extensive work in individual counties. Local staff provided through federal funds to assist county welfare departments includes 271 social service workers. In addition 133 full-time workers have been employed by the state welfare departments for assisting local units and organizing state-wide activities, and 96 additional workers have been employed part-time by state welfare departments for carrying on the same program. In the field of child welfare, as in those of maternal and child health and crippled children, a shortage of well trained workers with experience in the special field delays and handicaps the program.

On the whole, the progress made in these various programs for the health and welfare of children is most encouraging. The figures just reported are based on the first 5 months only. Much more new work that was planned during the earlier months is now being put into operation. As the plans go forward, however, it becomes more and more evident that a preventive program, whether in the health or social welfare field, that is not supported by adequate facilities for correction of

handicapping defects or for the care of the more serious illnesses and maladjustments and is without resources to provide adequate food, shelter, and clothing, is itself seriously handicapped. Physicians may offer the best type of health supervision to mothers and children in conference or office, but unless facilities for adequate maternity care at delivery or for correction of the physical defects of children, or for their care during illness, are available to all, including those unable to pay for these services, the value of the health supervision given may be to a great extent lost.

A public health nurse can go only a certain distance in her maternal and child health program without adequate medical support, sufficient economic resources, and the assistance of social case workers for special problems. A child welfare worker must have at her command certain facilities to aid in the handling of children with serious social maladjustments. Treatment must be instituted quite as much for this socially handicapped child as for the physically handicapped, and knowledge and understanding of social causes and skill in handling the procedures of treatment are as essential for social adjustment as is medical skill and nursing in caring for the physically sick.

The need for correlated action by workers in the fields of health and social welfare becomes more and more evident as progress is made in the establishment of the basic services under the Social Security Act. Opportunity for demonstration of the effect of combined medical care and social treatment is made possible under the section of the act providing services for crippled children; opportunity for correlation of the health and social services for children living in rural areas will be increasingly possible as the establishment of county-wide programs of child welfare and child health provides the mechanism for this coördination.

The maternal and child welfare services are but a part of the total program for social security. The basic economic provisions of the act and of the whole relief program as well as the provisions for general public health and for aid to dependent children lay the foundation on which the special health and welfare services to mothers and children can be built. The need to focus attention on the child and his needs as a growing and developing individual must nevertheless still be of major concern in all our planning in the field of social welfare.

NOTES

FIGURE I—Since this map was prepared the following plans have been approved: maternal and child health services, Oregon; services for crippled children, Hawaii; child welfare services, Arizona, Delaware, Massachusetts, Michigan, North Dakota, and Ohio.

FIGURE II—This chart is based on requests from 47 states, Alaska, Hawaii, and the District of Columbia, as of October 15, 1936. Though a few states were not able to match in full the allotment for maternal and child health services for the fiscal year 1937, the total amount requested by the states for 1937 actually exceeded by $22,-166.59 the $3,800,000 authorized for annual grants because certain states were able to match part of the funds carried over as balance from 1936.

FIGURE III—This chart is based on requests from 38 states, Alaska, and the District of Columbia. A few states were not able to match in full the allotment for crippled children for the fiscal year 1937; others were able to match the full amount for 1937; and still others the full amount for 1937 and also part of the funds carried over as a balance from 1936. It is anticipated that at least the full amount authorized on an annual basis will be requested before the end of the present fiscal year.

FIGURE IV—This chart is based on requests from 36 states and the District of Columbia.

Immunity to Virus Diseases*

ERNEST W. GOODPASTURE, M.D.

Professor of Pathology, Vanderbilt University Medical School, Nashville, Tenn.

TO understand thoroughly the mechanism of immunity to infection it would be necessary to know the factors concerned in the phenomena of susceptibility and invasion of the host; that is, the phenomena of pathogenesis. Unfortunately, at the present time knowledge of the pathogenesis of many infectious diseases does not rest upon a scientific foundation, and there is necessarily much empiricism in attempts to combat them. If you will look through the voluminous literature on the subject of immunity you will find a great deal about phagocytosis and antibodies and complement in general, but you are likely to look in vain for a scientific explanation of an acquired resistance to any specific infectious agent. Take the common disease typhoid fever for an instance. After the typhoid bacillus enters the mouth, knowledge of its adventures in the host which terminate in typhoid fever, practically ceases; and although vaccination by the introduction of dead typhoid bacilli seems to induce a limited resistance to subsequent infection, it is not known how this is, nor the reason for the more substantial immunity which follows recovery from an attack of the disease. Did we understand more thoroughly the pathogenesis of typhoid fever it is possible that even better means of inducing resistance would become available.

So it is with immunity to virus diseases. It is a very encouraging fact to those who are concerned with problems of prophylaxis that most virus infections leave the recovered patient solidly immune to a recurrence of the disease. Sooner or later we shall know how this is brought about, it is to be hoped. Then we should be able to protect without inducing disease.

There is, no doubt, a long chain of reactions between the infectious agent and the host, which leads to disease and to immunity. The weakest link in this chain should be broken, and the weakest link may be a different one for each type of infection. At the present time we do not know all the links, and fact must be supplemented by hypothesis, so that further pertinent data may be acquired.

Let us enumerate briefly some of the facts concerning immunity to virus infection, for with them must be constructed the temporary scaffold of experimental hypothesis.

1. *Most virus diseases are followed by a protective immunity.* In some cases the immunity is lifelong, in a few instances it is relatively brief. Among the former are smallpox, measles, mumps, yellow fever, and perhaps poliomyelitis. In the latter group are the common cold and influenza, diseases probably caused by cytotropic viruses, and the common fever blister or herpes simplex.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

2. *Viruses act as though they are antigenic substances.* This is an obvious inference from the fact of specific immunity.

3. *Immunes may be carriers of virus for a considerable period of time* in the case of infection by at least some viruses. Instances of this event are better known in animal diseases, such as fowlpox and infectious anemia of horses, than in those of man. The idea however has been advanced that durable immunity in man may be due to residual virus following infection, or to repeated sub-infections, although there is no very good evidence to support this view, as of general applicability.

4. *The degree of immunity to a specific virus* is variable, in the same individual and in different individuals.

5. *Individuals may become immune to certain viruses without having* suffered clinical *evidences of disease.* This occurs in the case of the poliomyelitic virus, and it has been explained on the assumption that repeated sub-clinical infections are responsible. There is however another important conception, namely, that cells may acquire an immunity, that is, become unsuitable media for a virus, from nonspecific causes, such as age, differentiation, state of nutrition and other such changes which alter cells. Should this be true, it seems possible that methods could be devised to utilize such nonspecific means of inducing resistance to certain virus infections.

6. *Treatment of susceptible tissue with chemicals may increase or decrease resistance to infection by some viruses.* Experimentally, such a procedure has proved effective in preventing nasal infection in monkeys by poliomyelitic virus. This result, however, is considered to be a blocking of a portal of entry, rather than an induction of an active immunity. What result this method may have in human prophylaxis remains to be seen.

7. *Subjects immune to a virus following infection usually contain specific neutralizing antibodies in their blood.* There is thus evidence of a humoral response to specific antigens present during virus infections.

8. *Prophylactic administration of serum of immunes may passively protect* for a relatively short time. Advantage of this fact has been taken in prophylaxis against measles, mumps, and canine distemper. Humoral antibodies evidently may prevent, under some circumstances, invasion by viruses.

9. *Administration of serum from an immune during the course of virus* infection is of little or no avail, and there seems to be no proven antitoxic effect.

10. *Recurrent attacks of a virus infection may take place in individuals whose blood contains neutralizing antibodies.* An example of this is to be seen in recurrent herpes simplex or fever blisters.

11. *Immunity to reinfection by a virus may occur before the active disease or lesion becomes quiescent or healed.* Warts and the salivary gland disease of guinea pigs are good illustrations. In such cases individual cells perhaps become immune more slowly than antibodies appear in the blood.

12. *Some viruses may be so modified by passage through an alien host that subsequent infection in an original host may be very mild, but sufficient to confer solid immunity to the virulent strain.* This of course is the basis of Jennerian vaccination, and the principle is now used in other instances such as the induction of active immunity to yellow fever by the use of mouse-brain virus.

13. *Inoculation of virus into an area not a natural portal of entry may lead to a mild infection followed by immunity.* In some instances, for example, immunity to poliomyelitis may follow intracutaneous inoculation of monkeys. But the method is not yet safe.

14. *There may be distinct antigenic strains of the same virus, which do not effectively immunize against each other.* For example the two or three strains of the virus of foot and mouth disease.

15. *In some instances in spite of the presence of specific neutralizing substances in the blood, there is little or no resistance to specific infection by a virus through natural channels.* This may be the case apparently in experimental poliomyelitis in monkeys. Rivers, Andrews, and others have demonstrated experimentally that certain living cells from normal or immune animals *in vitro* will permit growth of virus. But infection of these cells may be prevented by treatment with immune serum prior to but not after brief contact with active vaccinia or herpes virus.

16. *Administration of apparently non-infectious or killed virus as a vaccine usually does not result in protection.* If protection occurs under these circumstances it is questionable whether all virus activity was destroyed.

17. As a corollary it may be true *that all acquired immunity from the administration of virus vaccine results from active,* though *unrecognized, infection.*

Here then are a group of facts and inferences concerning immunity to virus diseases which at first glance seem to

be very confusing and to possess little analogy with other types of infection. In order to comprehend them intelligently and to deal with them experimentally in such a way that they may be useful, it is necessary to construct hypotheses into which these facts will reasonably fit. Only then may we utilize them to best advantage to forward experiment. It may be useful therefore to refer to some theoretical considerations which may be appropriate.

Infectious microörganisms reproduce themselves within the infected host under different conditions. For example, some grow only within the body fluids, some may grow either in the body fluids or within certain host cells. Still others seem to require the living protoplasm of the host's cells as a medium of growth. I have recently classified these groups as extracellular parasites, facultative intracellular parasites and obligate intracellular parasites.

It is not known whether viruses are living parasites or not, but all the knowledge we have of them indicates that they require, as do the obligate intracellular parasites, the environment of living cells of the host for their multiplication. They are therefore said to be cytotropic agents.

In order to emphasize the importance of an understanding of pathogenesis in relation to immunity let us contrast some of the theoretical possibilities with reference to the mechanisms of resistance to a group of parasites which invade and multiply in the fluids of the host, and the groups of viruses which seem to require the internal medium of living cells.

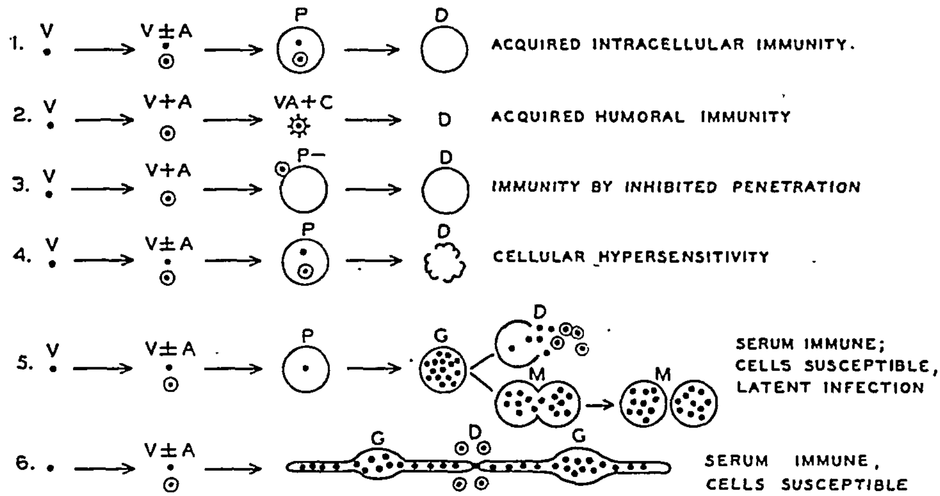
Let us consider acquired immunity to the extracellular bacteria first. The bacteria on entering the fluids of the host may become affected by opsonins or other antibodies, and be rendered more easily phagocytosed than normal. In this way they may be removed before they have a chance to induce disease. Or they may come in contact with lysin, be rendered soluble by complement, and destroyed before they gain a foothold.

These two possibilities, namely phagocytosis and the action of humoral antibodies, seem to be the chief, if not the only theoretical mechanisms for preventing infection in the actively immune host under the circumstances of invasion and growth of the microorganism in the fluids of the body.

As we have already stated, the viruses seem to require a living intracellular medium for reproducing themselves. The introduction of this element, the essential, living, host cell, into the pathogenesis of infection complicates matters considerably. For example, if virus is introduced into the fluids of a resistant host it may be either dissolved directly, or destroyed by phagocytosis, before it comes in contact with its required medium. If it does not reach susceptible cells no infection results. On the other hand a specific antibody often makes its appearance in the serum of a host as it acquires immunity, and this antibody may in some way prevent the virus from entering the susceptible cell. The action of antibody may enable complement to destroy virus before it enters the cell.

But these do not exhaust the possibilities. The virus may enter previously suspectible cells only to find them, after immunity is established, unsuitable for its reproduction, or so hypersensitive to its presence that they die before the virus can set about multiplying. Supposing that virus escapes the antibodies of the blood, it may still enter cells that permit its reproduction, if cellular immunity has not developed. Then it may grow, irritate the cell to division and thus enlarge the sphere of its influence; but

THEORETICAL MECHANISMS IN IMMUNITY TO VIRUSES



V = VIRUS PARTICLE A = HUMORAL ANTIBODY P = PHAGOCYTOSIS
C = COMPLEMENT M = MITOSIS G = GROWTH
P− = NO PHAGOCYTOSIS D = DESTRUCTION OF VIRUS

if it gets out of the cell the antibodies prevent its entrance into other cells. However it may persist, latent, within the cells and, taking advantage of opportunities, cause disease again.

The theoretical behavior of virus within a susceptible cell surrounded by fluid which contains effective antibodies is of especial interest in those infections which involve the architecturally complex cells of the nervous system. Structurally the neurons differ from most other cells of the body in the possession of very long, attenuated, cytoplasmic processes which may extend from the central nervous system to the periphery, or from the periphery, through ganglia, into the spinal cord or brain. If a virus can utilize the living cytoplasmic medium for reproduction then it seems obvious that a neurotropic virus might grow along one of these cellular processes from a peripheral portal of entry to its central terminus or *vice versa*. Another structural feature of neurons is that terminal cytoplasmic processes of one cell come very close to, or actually are in contact with, processes of the main body of other neurons, and it seems theoretically possible that virus might progress from one cell to another along these channels without exposing itself to the extracellular environment.

This is exactly what seems to happen in the course of neurotropic infections, and it has been demonstrated, in the case of experimental poliomyelitis among others, that virus may progress and the disease develop as usual, though specific circulating antibodies are present in the serum.

Because virus inside living cells should be protected from the action of circulating antibodies, it is not surprising theoretically that the introduction of immune serum during the course of disease does not seem to be of benefit. It is possible that some virus passing from one cell to another or otherwise discharged from an infected cell, as in the presence of necrosis, may

be inactivated and further extension inhibited or reduced; consequently serum therapy may possibly offer some advantage.

Possible explanations of certain facts of immunity to virus diseases, on the theory of cytotropism, may be partially illustrated graphically on the chart.

The theory of cytotropism of viruses, which hypothesizes that these active agents require a living intracellular environment for multiplication, fits best the known facts concerning the reaction between the host and the virus during infection; and it offers constructive suggestions for analyzing conditions of resistance which often supervene.

This theory does not necessitate a rigid definition of a virus, a requirement which at the present time would be impossible of fulfillment; for it is not known whether viruses are living parasites or sorts of autocatalytic ferments. But it is known that they act as though they were specifically antigenic. In this respect they behave like the antigenic proteids; and whether living or inanimate they would require the activity of living cells for their reproduction.

Because viruses are known to act like antigens and because experience of immunology up to the present time has been largely concerned with the study of serological antibody response to foreign proteids, it has perhaps been too generally expected that parenteral injection of inactive virus-containing materials would result in the production of a protective immunity. Such an expectation has not been realized. It seems probable rather that active immunity has only been induced by the introduction of active virus, and then only if infection, even though an inappreciable one, ensued. The immunizing antigen seems to be a very labile one. It is possible that it is produced only during infection.

The mechanism of the humoral antibody effect is as yet not understood, and the mere presence of antibodies in the blood is not an adequate assurance that the subject bearing them is immune. This is true especially in those viral infections in which the active agent has a predilection for the cells of the nervous system. The cytotropic hypothesis assumes under these circumstances that virus enters exposed neural processes without subjection to contact with antibody-containing fluid.

The very complexity of the pathogenesis of virus diseases may underlie the quite general occurrence of immunity following infection, because of the necessity for the fulfillment of many conditions in order that infection may take place; and likewise this complexity, as it becomes better understood, may offer exceptional opportunities for prophylaxis by the breaking at some vulnerable point of a long chain of necessary interactions between the host and its invader.

Epidemiology and Symptomatology of Staphylococcus Food Poisoning*

A Report of Recent Outbreaks

GEORGE A. DENISON, M.D., F.A.P.H.A.

Director of Laboratories, Jefferson County Board of Health, Birmingham, Ala.

FOOD poisoning due to staphylococci was first reported by Barber [1] in 1914. At the present time 18 outbreaks have been recorded in which the offending staphylococci were shown to be toxic for man or monkey—by the ingestion of milk or broth cultures in 3 instances, and by the ingestion of filtrates in 15 instances. The incriminated foods have been cake and custard-filled or cream-filled bakery goods [2, 6, 7, 8, 10] in 10 outbreaks, raw milk [1, 4, 12, 13] in 4, while cheese,[3] chicken gravy,[5] chicken salad,[9] and tongue sandwiches,[11] were each responsible for a single outbreak. In addition there remains a significant number of food poisoning outbreaks in which staphylococci were thought, for good reasons, to have been the etiological factor though full confirmation is lacking.

The following report of recent outbreaks of food poisoning serves as a reminder of the growing importance of the problem, and is perhaps of value for the added clinical information it may contain.

On the morning of March 27, 1936, a Birmingham physician reported to the Board of Health that he had attended 12 Ensley high school students, all sick with food poisoning after eating cream puffs for lunch on the 26th. The severity of the illness varied though all had the same general symptoms.

Investigation disclosed that the school lunch-room was clean, and its operations met the sanitary requirements of the Board of Health. The lunch-room personnel had not recently changed, none had been ill, and bacteriological examinations (completed 6 months previously) had not disclosed carriers of intestinal pathogens.

For several months the lunch-room had served cream puffs purchased from the same bakery. On the day of the outbreak 18 dozen had been purchased; 4 dozen of these were taken from the school to a neighboring café where most of them were later recovered. There were 693 students fed; 165 ate cream puffs, and 94, or 57 per cent, of these were taken ill. The 528 students who did not eat cream puffs were not sick. Six additional cases developed from cream puffs taken home by lunch-room supervisors and eaten by individuals for the evening meal. In all, 122 cases were discovered, 94 from the school, 8 from cream puffs carried away

* Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 24, 1936.

from the school, and 20 from cream puffs sold to 3 cafés and from the bakery truck.

It seems significant that, among 65 students who became ill after eating cream puffs for dessert, following the ingestion of other food, the onset was somewhat more delayed, and the illness decidedly more severe than among 29 who ate only cream puffs. Variations in the concentration of the gastric juice may partly explain apparent differences in susceptibility of these students to enterotoxin. Borthwick[14] states that the active principle of toxic staphylococcus filtrate is destroyed or reduced at a pH lower than 6.8 or higher than 7.8, and he reports rendering guinea pigs suceptible by adjusting the reaction of the stomach contents to a pH of 7.3.

Detailed clinical histories were obtained from both the victims and their attending physicians. The more typical cases may be described as follows:

Within 2–4 hours after eating there was first noticed a feeling of nausea. Severe abdominal cramps developed and were quickly followed by vomiting which was severe and continued at 5–20 minutes intervals for 1–8 hours. The vomitus was blood streaked in 13 per cent of the cases. A diarrhea of 1–7 liquid stools usually began with the vomiting or several hours after its onset. Blood, not infrequently, was present in the stool. During the acute stage the temperature was normal or subnormal, the pulse noticeably increased, there were cold sweats, prostration was severe, and the patients were very definitely in a state of shock. Headache was mild and of a short duration. Muscular cramping, usually of the flexors of the legs, was present in the majority. Dehydration was marked in some.

While the acute symptoms usually lasted only 1–8 hours complete recovery, because of prostration, was delayed for 1–2 days. During this time temperatures of 100° were not uncommon. Three cases were hospitalized. There were no fatalities.

These symptoms with their variations are summarized as follows: The most common interval between eating and the onset of illness was 3 hours. Eighty per cent were ill by the 4th hour, while in a small number the onset was delayed for 6, 7, and 8 hours. Twenty-one per cent were ill only for the short period of 1–4 hours while in 36 per cent recovery was delayed for 25–48 hours. Vomiting was the most

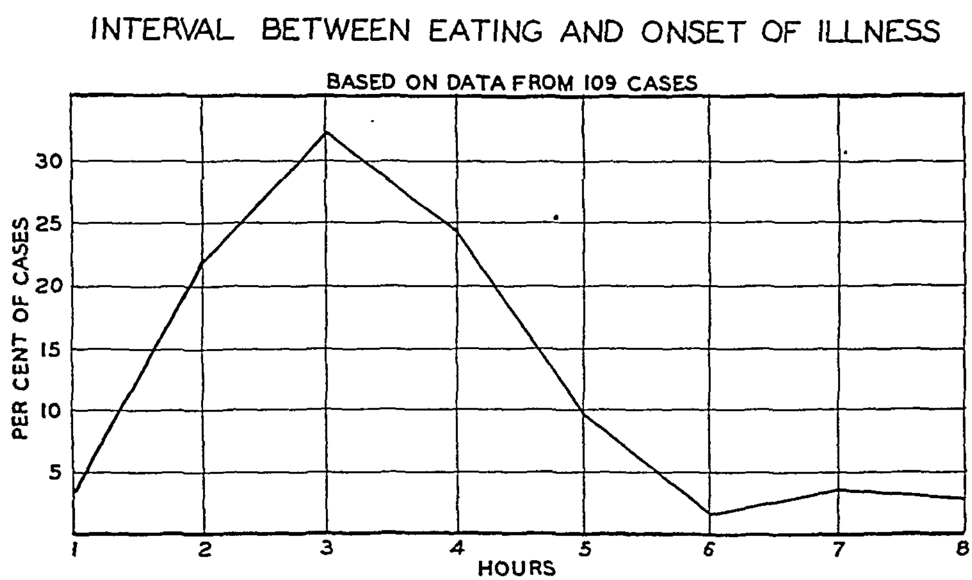

FIGURE I—Interval Between Eating and Onset of Illness

pronounced symptom, and in 50 per cent was described as "continuous." In the majority of cases (92 per cent), however, vomiting had ceased within 5–8 hours. There was severe vomiting in 78.2 per cent, severe abdominal pains in 62.5 per cent, mild diarrhea (1–7 stools) in 72.8 per cent, mild and usually transient headache in 58 per cent, mild muscular cramps in 51.3 per cent and sweating in 67 per cent. Prostration, dehydration, and the degree of shock varied accordingly.

TABLE I

SYMPTOMS OF FOOD POISONING

	Information from No. of Cases	*None* %	*Mild* %	*Severe* %
Vomiting	122	12.1	9.7	78.2
Pains in abdomen	122	4.7	32.8	62.5
Diarrhea	103	12.6	72.8	14.6
Headache	101	29.0	58.0	13.0
Muscular cramping	113	36.3	51.3	12.4
Sweating	100	33.0	67.0	

It should not be inferred from this discussion that the clinical features of staphylococcus food poisoning are distinguishable from those of Salmonella food poisoning, for such is not the case, only bacteriological studies are dependable. It is true, however, that the onset of illness in outbreaks due to the staphylococcus is usually within 2–4 hours after eating, and those due to the Salmonella group usually 12 hours or longer.

On inspection the bakery which furnished the cream puffs was filthy. Not only this, but certain conditions which prevailed were disgusting if not positively revolting. Three grossly insanitary toilets were repugnant and obnoxious. The building was not fly-proof and flies were embracing these toilets and the bakery products as a regular rendezvous. There were no proper washing facilities for the 35 employees, and no hot running water on the premises. Wash water for the utensils had the consistency of pea soup, no rinse was used, and the utensils were subsequently wiped with a dirty cloth. The greater part of the large and small equipment was inadequate, improvised, covered with filth, and in such a state of disrepair as to render cleansing impossible even under the best of conditions.

Raw materials were stored in open barrels entirely unprotected from dust, rats, and insects. The finished bakery products were subject to promiscuous handling and, before being wrapped, were often collected in an open garage within 15 feet of the insanitary toilets. Clothing worn by the employees was filthy. There was no history of recent illness, nor of boils or abscesses among the personnel. Such circumstances were not surprising, however, when we consider that for 3 years there had been no routine inspection of food establishments by the Board of Health because of severe financial restrictions. Other bakeries, inspected at a later date, were even more filthy—if such were humanly possible.

The cream puffs in question were all of one batch. The cream filling (approximately 12 gallons) had been heated in a copper kettle by steam for 6 minutes and then allowed to cool for 2½ hours before being placed in the shells. The heating temperature was indefinite and it is questionable whether the filling was rendered reasonably sterile. The time and conditions allowed for cooling were ideal for bacterial multiplication.

Nineteen cream puffs were examined. On physical inspection all appeared to be fresh. Direct microscopic examination of the filling showed large numbers of staphylococci and spore-forming bacteria. Agar plate counts on 4 specimens showed a bacterial content of 50 to 70 million per gram; 99 per

cent of these organisms were *Staphylococcus aureus*. From all 19 specimens *Staphylococcus aureus* was found in abundance, and in all *B. coli Communis* was also present. No bacteria of the Salmonella group were isolated and no carriers of these pathogens were found among the bakery personnel.

Jordan [3] has shown that staphylococci of diverse origin and cultural characteristics are capable of producing a filterable enterotoxin. Stritar and Jordan [15] conclude that there are no good criteria for the differentiation of various types of staphylococci and that in " food poisoning strains " there is no homogenicity of biochemical, hemolytic, or agglutinative characters. From studying a number of strains of staphylococci Woolpert and Dack [16] found that enterotoxin was not formed without the production of other exotoxins and that there seemed to be a rough correlation between the amount of food poison and the amounts of other toxins; these facts are borne out in this investigation.

Nineteen cultures of *Staphylococcus aureus* isolated from different cream puffs fermented maltose, dextrose, lactose, mannite, rhamnose, saccharose, and sorbite without gas; 6 fermented salicin after 1 week; none fermented xylose or inulin. All were hemolytic on blood agar. An antiserum made from one culture (C-3) agglutinated the remaining 18 cultures in amounts varying from ⅛ to ½ of the serum titer. These characteristics were the same for both enterotoxin producing and non-enterotoxin producing organisms.

Filtrates of 16 cultures were prepared according to Dolman's [17] modification of Burnet's method. Filtration was through Seitz pads (discarding the first portion of each filtrate) though Woolpert and Dack [16] have shown that these pads adsorb appreciable amounts of exotoxin. When tested with 1 per cent rabbit erythrocytes 5 filtrates produced no hemolysis, 10 were only slightly hemolytic when undiluted, while 1 (C-3) produced complete hemolysis in a dilution of 1/50. Using 2 rabbits, a filtrate of culture C-3 produced dermonecrosis in dilutions of 1/100 and 1/25. Filtrates of other cultures produced little (dilution of 1/5) or no dermonecrosis.

Filtrates for feeding experiments were prepared from broth cultures grown either in air or in 10 per cent

TABLE II

FEEDING EXPERIMENTS WITH BROTH FILTRATES OF STAPHYLOCOCCUS AUREUS ISOLATED FROM CREAM PUFFS

Culture	*Filtrate*	*Individual*	*Result*
C-6	6 c.c. 24 hr. broth	A	Not toxic
	20 c.c. 24 hr. broth	C	Abdominal cramps, headache
	6 c.c. 48 hr. broth	A	Not toxic
	12 c.c. 48 hr. broth	E	Not toxic
R-7	6 c.c. 24 hr. broth	D	Not toxic
	20 c.c. 24 hr. broth	E	Abdominal cramps, 6 liquid stools
	6 c.c. 48 hr. broth	E	Not toxic
	12 c.c. 48 hr. broth	A	Not toxic
R-1 *	10 c.c. 48 hr. broth	A	Not toxic
R-2 *	10 c.c. 48 hr. broth	B	Not toxic
C-2 *	10 c.c. 48 hr. broth	C	Not toxic
C-3 *	10 c.c. 48 hr. broth	E	Toxic (case E)
*	24 c.c. 48 hr. mixed	D	Toxic (case D)

* Grown in 10 per cent CO_2

carbon dioxide for 24–28 hours, and then passed through Seitz pads. In this way, and by graduating the dose, we hoped to produce filtrates only mildly toxic for human volunteers. Filtrates were diluted with 8 oz. of milk just before drinking. An equal number of controls took sterile broth in milk and none reacted. Human susceptibility to enterotoxin varies, and the number of persons used in feeding experiments was probably inadequate to prove the presence or absence of enterotoxin production in some of the strains tested.

Twenty c.c. of a 24 hour broth filtrate of staphylococci from two different cream puffs proved mildly toxic when fed to 2 individuals. One experienced mild headache and abdominal cramps, the other, abdominal cramps and 6 liquid stools. The onset for each was 3 hours. Other individuals receiving smaller amounts of 24 and 48 hour broth filtrates were not affected.

Cultures from each of 4 cream puffs were then grown in broth in an atmosphere of 10 per cent carbon dioxide for 48 hours and filtered. Ten c.c. of these filtrates were fed to 4 individuals while a 5th took 6 c.c. each of the filtrates from all 4 cultures, a total of 24 c.c. Three individuals were not affected.

Individual "D" who took the mixed filtrate was nauseated after 3½ hours, vomited 4 times in the course of 1 hour, the temperature dropped to 97.2° and pulse increased from 80 to 112. The white cell count rose to 15,000, blood pressure remained normal, and there was no diarrhea, prostration, dehydration, or abdominal rigidity. Recovery was complete in 4 hours.

Individual "E", who took 10 c.c. broth filtrate of culture C-3, was desperately ill for 3 hours. Nausea and vomiting developed 2 hours 45 minutes after drinking the filtrate. Vomiting was severe (5 times in the 1st hour). There were 5 liquid stools, 2 containing blood. Pallor was marked, the temperature fell to 96°, and the pulse rose from 84 to 130. Blood pressure fell from 120/80 to 60/40, the white cell count rose to 21,400 with 81 per cent polymorphonuclears. Headache

TABLE III

CASE "D"

Time	*Temp.*	*Pulse*	*Blood Pressure*	*White Count*	*Per Cent Polymorphonuclears*	
0	98.6	80	116/80			Drank 6 c.c. each of broth filtrates from cultures R1, R2, C2, C3. Total 24 c.c. in 8 oz. milk.
0:30						Ate light lunch
3:20 *						* Nausea and abdominal cramps
3:30			116/80			Vomited
3:40						Vomited
3:55						Vomited
4:00	97.2	112	116/80	12,200	71	
4:20						Vomited
4:30	97.8	80	116/80			
6:00				15,000		Recovered except for slight weakness
7:00						Complete recovery

* Onset 3 hrs. 20 min. after drinking broth filtrate. Nausea and abdominal cramps continued for 2 hrs.

TABLE IV

CASE "E"

Time	*Temp.*	*Pulse*	*Blood Pressure*	*White Count*	*Per Cent Polymorphonuclears*	
0	98.6	84	120/80			Drank 10 c.c. broth filtrate of culture C-3 in 8 oz. milk. Did not eat lunch.
2:45						* Nausea and abdominal cramps, slight dizziness
3:00						Vomited, large liquid stool, marked pallor
3:15						Vomited
3:30						Vomited, liquid stool
3:40						Vomited
4:00	97.4	120				Vomited, liquid stool
4:30	97.4	120				
5:00	96.0	110				
5:30	96.0	100	75/55	21,400	81	Bloody liquid stool
6:00	97.4	108	75/55			
6:30	97.0	130	60/40	16,400	77	Bloody liquid stool
9:00	98.6	110				Marked prostration

* Extreme nausea, abdominal cramps, and prostration continued for 4 hours from onset.

was mild at the onset and of short duration, there were cold sweats, and prostration was severe. There was no abdominal rigidity. Dehydration was moderate but probably did not entirely account for the increased white count. The acute symptoms passed in 4 hours but weakness persisted for 2 days.

The findings in these two experimental cases follow those of the mild and severe cases of food poisoning experienced in this outbreak and appear to establish *Staphylococcus aureaus* as the cause. The opportunities for contamination of the bakery products were so numerous that it seems highly improbable that the source of the infection can ever be determined. Cultures of staphylococci were isolated in large numbers from the throat of one of the bakery personnel, from various parts of the machinery, and from the feces of 1 patient. Their broth filtrates were not toxic with feeding tests.

The bakery was cleaned up and continued to operate. On May 11, 3 individuals, living in different sections of the city, were admitted to a local hospital severely ill with food poisoning. The symptoms were the same as those described for the first outbreak. All had subnormal temperatures and white cell counts above 10,000 (10,750 with 84 per cent, 11,850 with 78 per cent, 38,800 with 89 per cent polymorphonuclears). In addition each had marked abdominal rigidity (board-like in 2) and the general picture was that of an acute abdominal condition requiring surgery. In fact, a pre-operative diagnosis of "ruptured peptic ulcer" was made on 1 patient and a laparotomy performed.

Each patient had eaten in a different café and had partaken of cocoanut custard pie baked by the bakery involved in the first outbreak. Portions of two pies eaten by 2 individuals were recovered and found to contain enormous numbers of *Staphylococcus*

aureus. Twelve other persons were thought to have eaten portions of three pies involved but no other cases could be discovered. Following this incident, the bakery has been permitted to bake only bread and rolls.

It should be realized that the number of reported cases of food poisoning falls far short of indicating the frequency with which sporadic cases result from contaminated commercially prepared foods. Due to publicity given recent outbreaks in Birmingham numerous suspected cases of a sporadic nature have come to our attention, and we have every reason to believe that during the summer months such cases are of daily occurrence.

By way of controlling such outbreaks certain practices common to many bakeries should be eliminated. They have been emphasized in other reports but may well be repeated here. Custard-filling in the usual course of its preparation is heated to temperatures at which staphylococci will not survive, and failure to destroy the organism is evidence of improper cooking. Dack [2] has shown that the organisms in broth culture are destroyed by exposure to 80° C. for 15 minutes. McBurney [7] found that as many as 2,500,000 staphylococci per c.c. of liquid custard were killed by cooking at 85° C. for 10 minutes. To avoid contamination after cooking the filling should be properly covered, and cooled at refrigerator temperatures. Excessive handling of the shells or the filling should be avoided, and all machinery used should be thoroughly cleansed and properly sterilized. The finished product should be properly covered or wrapped, and stored at refrigerator temperatures. Obviously the building should be fly proof, and reasonably free of rodents and insects. Proper toilet facilities should be provided for the personnel. Machinery and equipment should be adequate to handle the volume of business undertaken.

Adequate inspection service, aside from checking all physical equipment, must exert some supervision over the methods of preparation and distribution of the food products. Those bakeries which cannot reasonably comply with regulations because of antiquated and improper physical equipment, or who refuse to comply for other reasons, should, at least, be promptly prohibited from making any product not subjected to the same oven temperatures as bread and rolls.

No matter how essential certain requirements may appear to the inspector they always seem unreasonable to the proprietor unless he understands why they are made. While educational programs are necessarily slow and time consuming, more progress can be expected if the proprietor understands how such control measures protect his business, as well as the public. Unless coöperation is obtained, inspection service reverts to purely police methods which are undesirable and often ineffective. Outbreaks frequently occur in bakeries that are scrupulously clean but where some breach of technic has presumably occurred. Educational programs directed toward plant operators and their personnel are, therefore, of considerable importance. Medical examinations and bacteriological attempts at detecting carriers would, as a routine measure, seem to offer little of definite value.

Finally, in the many cities where inadequate appropriations allow only a pretense at actual control of food products, it seems essential that the greatest effort be directed toward those small and large establishments which prepare, manufacture, and distribute foods, rather than the small retailers who may dispense products already contaminated before reaching their hands.

Scarlet Fever Control

LAST February, Dr. Hobson of Oxford published a most interesting series of cases and observations. He found that:

1. An *erythema is inconstant in infections* due to a haemolytic streptococcus.
2. It may be a feature of those due to a non-haemolytic streptococcus.
3. Though it is more frequent in infections due to haemolytic streptococci, it is a poor guide to the course, prognosis, or infectivity of the disease in a given patient.
4. Infections due to haemolytic streptococci *with or without an erythema*, are generally highly toxic, highly infectious, and have a striking association with sequelae of all kinds. *The appearance of an erythema is probably a favourable sign.*
5. An infection due to a non-haemolytic streptococcus may have sequelae in no way distinguishable from those due to a haemolytic strain, whether there is an erythema or not.

If, as he says, these statements and conclusions are sound—and they have not been refuted so far—then it is pertinent to consider what alterations in, or modifications of, existing practice and teaching should be introduced.—Andrew W. Forrest, M.A., M.D., Ch.B. (Edin.), D.P.H., Scarlet Fever Control on Modern Lines. Presidential Address at a joint meeting of the Home Counties Branch and the Fever Hospital Medical Service Group, *Pub. Health*, 49, 12:413 (Sept.), 1936.

Assistant Director, Junior Bacteriologist, and Assistant Chemist, Division of Biologic Laboratories, Massachusetts Department of Public Health, Boston, Mass.

THE multiplicity of methods proposed for determining the "strength" of bacterial vaccines indicates that all fall short in respect to one or the other of the two essential requirements, simplicity and precision. It usually happens that when simplicity is sought accuracy is sacrificed. When precision is demanded the method becomes complicated or cumbersome.

In principle, the methods proposed may be classified as those of:

1. Direct enumeration in a counting chamber
2. Indirect enumeration:
   (a) Wright's method
   (b) Colony count
3. Physical measurement:
   (a) Weight of dried bacteria
   (b) Volume of bacteria
4. Chemical measurement:
   (a) Total nitrogen determinations
5. Turbidity measurement:
   (a) Opacimetric
   (b) Nephelometric
   (c) Photometric
   (d) Photoelectric
6. Serologic measurement

No matter what method is adopted for standardizing vaccines the result is usually expressed in millions of bacteria per c.c. There is a growing feeling that this practice should be abandoned and that some other measure which more nearly represents the antigenic content should be adopted, because counts fail to take into consideration the size of organisms. Brown[1, 2] has proposed that the weight of the dried bacteria be substituted for the number of bacteria present, and has shown that the opacity of a bacterial suspension is intimately associated with the dried weight. Since antigens are very closely associated with proteins there is reason to believe that the total nitrogen of the bacteria might be an even better measure of the amount of antigen present. Mueller[3] has recommended the use of micro-Kjeldahl determinations for this purpose. Until there is some general agreement in regard to such a change, however, it seems more expedient to continue to express the bacterial content in numbers of bacteria.

Smith[4] in 1925 reviewed many of the papers dealing with methods of

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

standardizing bacterial vaccines and noted the general dissatisfaction with all methods then in use. He presented evidence of the marked inaccuracies of Wright's method and maintained that the direct count in the Helber counting chamber offered the most acceptable means of standardization. He admitted, however, that the results obtained varied with the observer and the technic used. Since the method is cumbersome and requires an average of several counts for accurate results, it has never come into general use. Most workers prefer to use the direct count for standardizing some simpler method which does not depend so much upon experience with the technic, dexterity, and constant practice.

The simplest and perhaps the most frequently used method is some means of determining the turbidity of bacterial suspensions. Holker[5] claims that measurements of opacity are subject to less variation than direct counts. Various kinds of standards have been proposed with which the opacity of the suspension to be standardized may be compared, some consisting of bacterial suspensions and others of insoluble inorganic substances in suspension. Baylis[6] has proposed a photometric method, and recently the photoelectric cell has been utilized for determining turbidities of bacterial suspensions. Most of these methods are subject to the criticism that they depend upon standard suspensions which change with age, and that therefore the standards must be re-standardized from time to time. Some also require complicated apparatus not usually available or readily kept in working order.

Gates[7] in 1920 recommended the disappearing loop as an instrument for standardizing vaccines. Holker[8] claims priority for the idea for Don and Chisholm.[9] Their apparatus was not strictly comparable to that proposed by Gates, nor did they claim to have originated it. They merely described a method which had been in use for several years for determining the turbidity of water samples but had not been applied to bacterial suspensions. Holker[8] states that he himself had independently worked out the method, but had discarded it in favor of an apparatus of his own design, which appears more cumbersome and probably no more accurate than the Gates apparatus. Some of the objectionable features mentioned by him have been eliminated by a modification described later in this paper.

The disappearing loop has been in use in this laboratory for several years for controlling the turbidity of vaccines for injection into horses. In addition to the advantage of having no standard tubes to deteriorate with age, it is useful because: (a) the apparatus can be assembled in any laboratory; (b) it is simple and easy to use; (c) experience with the apparatus is not of great importance; (d) the results obtained are quite accurate; (e) the size of the tube used is of little importance; (f) living cultures can be handled with ease and little danger.

During the time that this laboratory has been manufacturing typhoid-paratyphoid vaccine, one of the simpler methods (opacimetric) has been used to estimate the bacterial content of the three bacterial suspensions which are combined to make the triple vaccine. In comparing vials of triple vaccines made at various times it was noted that there was a considerable difference in opacity. An investigation was undertaken to determine the degree of variation and to find a method which would reduce it to a minimum.

The opacity of some of the monovalent vaccines prepared and standardized by the old method was determined with the Gates apparatus.

Typhoid vaccines supposed to contain 2,000 million bacilli and paratyphoid suspensions supposed to contain 3,000 million bacilli per c.c. showed marked differences in turbidity as gauged by corrected Gates readings.

Later in the study total nitrogen determinations by the micro-Kjeldahl method were undertaken. At that time the apparent variations in the bacterial content of the old lots of triple vaccines were confirmed. The total nitrogen of some lots was as low as 20 mg. per l., while others contained almost 60 mg.

The problem was to determine what corrected readings would represent 2,000 million or 3,000 million bacilli in these suspensions. This necessitated parallel corrected readings and direct counts on a number of vaccines, which were most easily made on experimental lots.

A MODIFICATION OF THE GATES APPARATUS

The original Gates apparatus consists essentially of a test tube holder with a sliding bar, calibrated in millimeters, to which is attached a nichrome wire loop. The method of use is simple, the loop being pushed under the surface of a bacterial suspension until it just disappears and the depth read off on the metric scale.

It was early discovered that consistent readings on the same vaccine were obtainable only under constant light conditions, otherwise readings made at different times of the day or on dark days and clear days are not within a satisfactory range. If a constant light is provided and all readings are made in a darkened room the readings are quite consistent.

The modified apparatus is a wooden box containing two 25 watt daylight bulbs. The inside of the box is painted with aluminum paint and the wires in the bottom are covered with a piece of white cardboard so that reflection will increase the evenness of the illumination. In the center of the top is a hole just large enough to admit a $\frac{3}{4}'' \times 6''$ test tube. Just behind the hole an upright, with an attached metric scale, is firmly fixed (Figure I). A piece of nichrome wire attached to a removable cap on the upright is bent down parallel to the metric scale and at a point even with "O" on the scale the wire is bent out at a right angle and a loop 3 mm. in diameter is formed so that it will be in the center of the tube when the bacterial suspension is in place for making a reading. A spring extending above and below the hole in the top of the box has enough tension to hold the tube securely at any level. The readings are made by observing the point on the metric scale opposite the top of the brightly illuminated meniscus. It will be noted that in the modified apparatus the tube is moved up and down until the loop disappears, whereas with the original apparatus the loop is moved up and down and the tube remains stationary. The electric bulbs are so mounted on each side of the hole through which the tube extends, and the holes for ventilation of the box are so placed, that no direct rays reach the eye of the observer.

4.3	1 + 1	14.0 +	14

from the apparatus and a tube containing the suspension to be standardized is inserted through the hole in the lighted box. With the loop inside the tube, the cap is replaced. The tube is raised slowly until the loop fades from view and its depth below the meniscus of the suspension is noted. Although the depth increases when the suspension is diluted the relation between the successive readings and the dilution is not inversely proportional, for reasons which are discussed in detail by Gates[7] and need not be repeated here.

By making two readings, one on the original suspension and another on a known dilution of the original, *corrected* readings can be computed which are inversely proportional to the dilution within certain ranges of opacity. These corrected readings are calculated by the following formula:

$$\text{Corrected Reading} = \frac{\text{Volume A (b} - \text{a)}}{\text{Volume B} - \text{Volume A}}$$

when "a" is the depth of disappearance in the original suspension; "b" that in the known dilution; Volume A the amount of the original suspension used in making the secondary suspension, and Volume B the total volume of the second suspension.

The formula is made unnecessary and the calculations are simplified if the dilution of the second suspension is expressed as 1 *plus* the volume added instead of 1 *to* the total volume (*e.g.*, 1 + 10 instead of 1 : 11). When this is done the calculations consist merely of dividing the difference between the two observations by the second figure indicating the dilution. The following example shows the simplicity of the calculations:

Original suspension, depth of disappearance	1.4 cm.
1 + 10 dilution of original, depth of disappearance	8.2 cm.
Difference	6.8 cm.

Corrected Reading: $6.8 \div 10 = 0.68$

POINTS TO BE OBSERVED IN USING THE APPARATUS

1. The depth of disappearance in the original suspension should always exceed 1.0 cm. When the suspension is too opaque, a dilution should be made on which to obtain the primary reading. The corrected reading obtained will now be that of the dilution, and in order to calculate the corrected reading of the original suspension it will be necessary to divide by the dilution factor. That is, if the dilution was 1:2 the corrected reading of the original will be ½ of that of the dilution.
2. Greater accuracy is obtained when the secondary suspension is as dilute as possible. Table I has been compiled from readings made in this study. It shows the best dilution to be used for the secondary reading when the original suspension has given primary reading.
3. When beginning observations it often takes a moment or two for the eye to become adjusted. A sufficient number of observations should be made so that 3 or more successive readings fall within a very close range.
4. Differences in visual acuity make slight but constant differences in the readings made by different individuals, so that it is well to

determine how closely the various persons taking part in standardizing vaccines will agree. These differences are minimized when the readings of two or three individuals are averaged.

5. As will be shown, the turbidity of bacterial suspensions decreases during heating, and also when standing in the presence of tricresol. It becomes stabilized rapidly after the tricresol is added, and there is little further change during the course of a year.

Preliminary Experiments — Because there was a tendency for the vaccines to clump on heating and subsequent centrifuging the first observations were made upon freshly suspended vaccines. It was soon discovered, however, that there was a considerable decrease in the count and turbidity after heating, centrifuging and contact with tricresol. For these reasons it was found advisable to delay standardization until after resuspending in salt solution containing tricresol. Moreover, when only smooth cultures were used in producing vaccines, clumping was minimized and more satisfactory counts were obtained.

Experimental Lots of Monovalent Typhoid Vaccine—Direct counts in the Helber counting chamber and corrected Gates readings were made on 23 experimental lots of vaccine produced from a smooth Rawlings typhoid strain, grown and handled in the manner used for routine lots. Each vaccine was made of the washings from 4 to 10 Blake bottles suspended in 40 c.c. of saline for each bottle. Counts and corrected readings were made on the vaccines when freshly suspended and after heating, centrifuging, and resuspending in salt solution containing 0.4 per cent tricresol. Only the observations on the resuspended vaccines are shown in Table II.

Corrected readings for 1,000 million bacilli were calculated for each of the 23 lots. Since counts and corrected readings are inversely proportional this consists of multiplying the observed corrected reading by the direct count and dividing by 1,000 million. The calculated corrected readings fall very close to the mean (3.48) of the 23. The variations from the mean would be much smaller if direct counts could be more accurately made. As many as 10 counts were made on some of the lots without getting close checks between them. The variations were often as large as 25 per cent.

Using a round number for the mean which errs slightly toward the more turbid side, a corrected reading of 3.40 can be considered as equivalent to 1,000 million typhoid bacilli. The counts indicated by the Gates readings were calculated on this basis for the 23 lots by multiplying 3.40 by 1,000 million and dividing by the corrected reading of each lot. In most instances the count predicted from the Gates reading corresponded very well to the direct count. The correlation coefficient between the two series is $+0.835 \pm 0.064$.

At this point in the study it was decided to include, as an additional check on the direct counts, total nitrogen determinations on these experimental vaccines.

Micro-Kjeldahl Determinations of Total Nitrogen—Attempts to make nitrogen determinations on the whole vaccine were not satisfactory. Amounts as small as 1 c.c. did not contain sufficient nitrogen to give accurate figures. It took several hours to evaporate the water from 5 c.c. and 10 c.c. samples and in addition duplicate and triplicate samples failed to agree. Mueller's [3] determinations are made on centrifuged bacteria. When this method was adopted, and 10 c.c. samples of the vaccines were centrifuged in the tubes in which digestion was to be done, determinations made on the sediment only gave good agreement between duplicate and triplicate samples. A surprising

3. $\frac{1000 \times 272}{13{,}000} = 20.9$

4. $\frac{272 \times 1000}{22.5} = 12{,}000$

fact was that the figure obtained in this way was usually as large, and sometimes even larger, than that obtained on the whole vaccine. The loss with the whole vaccine apparently occurs because a portion of the nitrogen is carried off with the vapor during the process of evaporation before digestion begins.

The figures given in this paper represent the total nitrogen of the bacilli only. It must be borne in mind that there is an additional 10 to 20 per cent of nitrogen in the supernatant.

Total nitrogen determinations (Table II) were made on each of the above experimental typhoid vaccines. The total nitrogen for 1,000 million bacilli was then calculated for each lot, the mean of the series being 22.2 mg. per l. Again using a round number toward the more concentrated side, a total nitrogen of 22.5 mg. can be considered as equivalent to 1,000 million bacilli. The counts indicated by nitrogen determinations were calculated on this basis for the 23 lots by multiplying the total nitrogen by 1,000

			Mean = 3.37			

million and dividing by 22.5. Again the counts predicted corresponded very closely to the direct counts. The correlation coefficient between the two series is $+0.843 \pm 0.060$. It will be noted that the counts estimated from the corrected readings and those from the total nitrogens run more closely parallel to each other (correlation coefficient: $+0.937 \pm 0.025$) than either estimate does to the direct count, which would indicate that both of these measures are more consistent than the direct count.

Application in the Standardization of Routine Lots—When the floods of the past spring required the rapid production of large quantities of typhoid vaccine, the figures on the experimental lots had just been accumulated. Corrected Gates readings were therefore substituted for the opacimetric method previously employed for standardizing monovalent vaccines to contain the desired number of bacteria. Total nitrogen determinations were then made on these diluted vaccines and a few direct counts were made. Table III gives the figures on 26 routine lots made at that time. The calculated corrected readings for 22.5 mg. of nitrogen fall within a satisfactory range from the mean.

Counts were estimated from both the

corrected reading and the total nitrogen for each lot on which direct counts were made. Again it will be noted that these estimates run more closely parallel to each other than either estimate does to the direct count. Estimates were made for the remaining lots and the correlation coefficient between the two series computed. In this case the correlation between the counts indicated by the corrected readings and those indicated by the total nitrogens was $+0.979 \pm 0.008$.

The first 9 lots were intended for distribution as monovalent vaccine during the emergency and were standardized as soon as prepared at 1,000 million bacilli. Because the turbidity had not become stabilized, they could not be adjusted exactly to a corrected reading of 3.4, an allowance for a decrease in turbidity being necessary. All the readings in Table III are those made several days after standardization. An error in calculation of volumes caused Lots 184A, B, and C to be diluted too much.

The remainder of the lots were also standardized as soon as resuspended, but were meant to contain 2,000 million bacilli (corrected reading of 1.7). If these suspensions could have been set aside until the turbidity became stabilized, they could have been more accurately standardized. Most of the lots contained more than 2,000 million bacilli. This was intentional as more salt solution can be added to bring up the volume when mixing with the paratyphoid fractions of the triple vaccines. Since a year's supply of vaccine was accumulated by the end of the emergency, no observations on additional lots have as yet been made.

The Standardization of Monovalent Paratyphoid Vaccines—Because our *B. paratyphosus* A culture is slightly smaller than our smooth Rawlings typhoid strain and our *B. paratyphosus* B culture is very much larger, the same corrected reading cannot be used in standardizing them. We plan to obtain a smooth culture of each more nearly of the same size as the typhoid strain before accumulating a series of observations on experimental lots of vaccines made from them. Meanwhile we are standardizing them by total nitrogen determinations.

DISCUSSION

Our experience with the Gates apparatus has convinced us that the method is as accurate for routine use in standardizing bacterial vaccines as direct counts. Since this is so, the simplicity of the method should cause its wide adoption in the standardization of bacterial suspensions of all kinds. Usually it would be necessary to do parallel counts or total nitrogen determinations on only a few vaccines made with a particular organism to determine the corrected reading corresponding to the bacterial content desired.

When it was determined that 1,000 million typhoid bacilli represented a total nitrogen of about 22.5 mg. per l., it was apparent that many lots of vaccine which had been distributed contained fewer than the labeled 2,500 million organisms per c.c. Only an occasional lot had contained the estimated amount of nitrogen ($2.5 \times 22.5 = 56.25$) for that number of bacilli. To push up the bacterial content suddenly did not seem advisable. Lots have therefore been standardized for the time being to contain about 2,000 million bacilli (45 mg. N.). A questionnaire was sent recently to a number of state institutions where large numbers of patients are routinely given these vaccines. Replies indicated that reactions during the last few months had not increased in frequency or severity with the increase in bacterial

content. Two complaints had been sent to us just before the questionnaire was sent out. In one instance the lot used contained 58.7 mg. N. per l.; the second contained less than 40 mg. N. Unless undesirable reactions begin to be reported, the bacterial content of the triple vaccine will be increased from time to time until it contains the labeled 1,000 million typhoid bacilli and 750 million of each of the paratyphoids.

SUMMARY AND CONCLUSIONS

1. A modification of the Gates apparatus, which increases its accuracy, is described.
2. This modified Gates apparatus offers a simple and accurate method of standardizing bacterial vaccines.
3. When a typhoid vaccine made from a smooth Rawlings strain is standardized at a corrected Gates reading of 3.40 the likelihood of its containing exactly 1,000 million bacilli per c.c. is as great, if not greater, than if it is standardized by direct count.
4. The total nitrogen of the centrifuged bacilli from such vaccines, standardized at a corrected Gates reading of 3.40, is very close to 22.5 mg. per l.

Rejuvenation Theories Biologically Unsound

I AM quite sure that we shall overcome all those causes of sickness which can be overcome by the full exercise of the powers we possess, or which further research may give us, but I see no warrant whatever for supposing that we can prolong human life indefinitely or that we can overcome the infirmity of age.

It seems to me that the favourable interpretation which some have placed on experiments in tissue culture and the results of researches into endocrine functions, indicating the possibility of rejuvenation, is biologically unsound, though I am prepared to admit that they do offer a hope that we may arrange human ageing to be more regular and so diminish the numbers which die from irregular deterioration of their organs.—Dunstan Brewer, D.P.H., *Ann. Rep., Medical Officer of Health for the Year 1935*, Borough of Swindon, p. 6.

Mental Hygiene in Public Health*

W. T. B. MITCHELL, M.D.

Director, Mental Hygiene Institute; Assistant Professor of Mental Hygiene, Department of Preventive Medicine, McGill University, Montreal, Canada

WHAT is mental hygiene? What can we hope to accomplish in the way of preventing mental disorder? What content is available for the formal presentation of mental hygiene principles and practices? Where should the emphasis be placed in developing more adequate and widespread constructive attitudes to mental disorder and mental health? To whom or to what groups does the responsibility for the promotion of mental health and prevention of mental disorder fall?

These and other questions are being persistently presented from the field of public health and preventive medicine to specialized workers in the field of mental health. They seem to be indicative of the growing realization for the necessity of including mental health considerations in public health programs. I hope they indicate a realization that mental health is not separate and apart from physical health. Health, physical and mental, represents one single complex state of adjustment.

When a physician with broad representative interests in the fields of public health and preventive medicine, with evident interest in finding an answer, issues the challenging question: " Now, just what is mental hygiene? " —what shall we say? Perhaps we are justified in countering with: " What is preventive medicine? " The counter question is not one way of evading the original query. It actually implies the answer because the principles which have applied in the field of preventive medicine are exactly the principles which must apply in any program to promote mental health and prevent mental disorder.

On the basis of our present knowledge of how the individual grows and the factors in his routine and environment which favor healthy physical growth, of how he responds satisfactorily or fails in the face of certain environmental hazards, this knowledge together with some understanding of individual constitutional factors, represents the basis upon which the present program for insuring healthy physical growth and avoiding physical disease has been established. Health programs have proceeded:

1. To provide so far as is possible the positive factors which favor adequate growth
2. To simplify the environment by the removal of certain hazards
3. To build up the resistance of the individual through establishing specific immunities to certain other hazards.

Through general educational measures larger and larger groups in the community have been acquainted with the principles and factors which make for

---

healthy growth and the means to be taken to avoid sickness.

If for the moment for the purpose of convenience in this discussion, we might consider mental health apart from physical health, exactly the same principles and practices are applicable for the promotion of mental health and the prevention of mental disorder. As to how we shall proceed, this must depend upon:

1. What we now know or may learn about mental growth and the nature and causes of mental disorder
2. How far we can evolve from this knowledge, adequate mental health principles and practices
3. How far we can effect a satisfactory integration of these principles and practices in public health and medical programs

Mental health implies an adequate relationship as between the individual and, reality in the form of experiences, reality as it exists outside the individual in his physical and social environment, and reality as it exists within himself in the terms of his own feelings, thoughts, desires, drives to action, assets, and limitations. Mental disorder, when it occurs, represents as does physical disease, some failure of the individual in relation to experience, with exactly comparable evidences of dysfunction and distortion or arrest of normal growth. The individual becomes what he does by virtue of his inherited constitutional make-up together with what goes forward in the way of growth. What the individual inherits, on either the physical or the mental constitutional aspects, are "potentials for growth." So far as we know he does not inherit mental disease as such nor the attitudes and personality characteristics which we see manifested in his later behavior. He inherits potentials which in the course of experience are developed and modified to produce what we later find in the way of personality adjustment.

Apart from the general health measures for the elimination of the physical factors, organic and toxic, which are accompanied by disturbed mental functioning, there is only one major gateway to mental health and that is through mental growth. Mental growth represents just as definite and orderly a process as does physical growth. Adequate mental growth implies a progressive re-distribution of interest-energy from self to outside interests. In the course of this process there must take place a progressive re-placement of infantile self-values and infantile sources of satisfaction by more adult social values and adult satisfactions. That is, this forward-going process involves a continuous relinquishing of values which are normal for one phase of development in favor of the values which we recognize as normal for a later period. Self-interest of course is maintained throughout life as perhaps the principal motivating factor for activity. The healthy mature adult, however, finds his self-satisfactions largely in terms of interest and effort directed away from himself rather than in terms of the naïve, dependent, demanding self-values of the infant. On the other hand, the emotionally immature adult, has retained in his values much of the infantile dependent quality which demands a great deal in the way of ministration and attention to his immediate needs which blocks his ability to get satisfaction out of independent effort and which is impatient of any thwarting or delay in securing his objectives.

The person who is not reasonably mature from an emotional standpoint is essentially a poor mental health risk. There is a lack of essential adult satisfactions, an underlying feeling of inadequacy in relationship to his fellows which determines an inadequate response to any sort of critical experi-

ence in the form of disappointments or deprivations or in the face of demands for unusual effort. One sees clinical evidences of inadequate maturity at all chronological levels and we must have standards and criteria available to enable us to determine in any cross-section the adequacy and the significance of the personality responses which we observe.

Today I have seen a man of 45—a man with fine intellectual capacity, holding an important executive position in business but responding in a way which is habitual for him, in the face of difficult or disappointing situations. He has been in bed for over a month following a slight influenzal cold. He berates the inefficiency of his physicians because they tell him that his lungs and heart are all right. He stresses his difficulty in breathing, his general weakness, but on the other hand he is being ministered to as completely as he was when he was 6 months old.

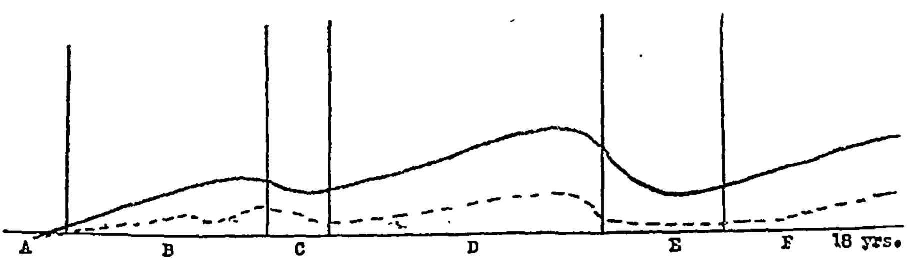
In this same clinical day I had seen a man of 42 who, in the past 6 or 8 years, has been described as a manic-depressive person. There have been periods of extravagant, hypomanic activity leading to indiscretions in behavior, over-indulgence in alcohol, social and business indiscretions. These periods have been followed by depressive phases in which he is exaggerating his feelings of inadequacy and using these feelings as a way of avoiding what he feels are onerous and difficult responsibilities. In this particular problem it does appear that the mental disorder is not in response to constitutional biological factors, but that we are dealing with a person who is emotionally immature, whose infantile self-values have been so completely maintained and reinforced by over-protection during the developmental years, that he is quite unable to accept with satisfaction the responsibilities which adult life has brought. Over a period of 17 or 18 years he has used his domestic situation in an attention-getting, bolstering way, but all the time with an underlying discontent and dissatisfaction with what he vaguely has realized were inadequate responses. This patient's reaction to the breaking up of the domestic situation has been a further depressive episode in which, instead of being able to crystallize the situation and recognize his responsibilities, he spends his time bewailing his own lack of fitness, his inability to accept his business responsibilities and make decisions, his discomfort in having to face his daily routine and social obligations alone. He is like a child in his helplessness, crying for a lost lollypop but unable to make any constructive effort to fill in the gap.

The process of progressive re-distribution of interest-energy and the replacement of infantile values goes forward satisfactorily, given reasonably favorable conditions, just as physical growth proceeds under comparable reasonably favorable conditions. The period of infancy and preschool growth is tremendously important as the foundation for later healthy mental development. The parent is the strategic person in either promoting or inhibiting an early healthy mental growth process. One can hope for a gradual progressive learning of new ways of finding satisfaction and the progressive replacement of values from period to period during growth, only under conditions which permit a reasonable freedom for independent activity and experimentation.

Interference in the form of overprotection, over-solicitous and fearful attitudes for the growing child, unwise emphasis and conflict over health routines, repressive discipline, all tend to reinforce infantile self-values and

prevent adequate growth in the direction of emotional independence, emotional self-control and intellectual progress as these increments in growth and learning are marked by increasing self-confidence and fortitude in the face of difficult situations and disappointments, patience in the face of failure and thwarting and the acquiring of satisfying new skills and knowledge. The individual learns and grows by doing. If his spontaneous expression and experimenting is thwarted through repressive interference of whatever kind, or if his satisfaction from his own effort is consistently overshadowed by adult approbation or disapproval, there is a maintenance of infantile values and forms of satisfaction which does not promise well for a later healthy independent adjustment and a satisfactory, satisfying assumption of adult responsibilities.

The best single criterion which we have for healthy mental growth is in terms of this progressive re-distribution of interest-energy and in cross-section at any chronological level; our best single criterion for mental health is in terms of how completely the individual's interests and energies are distributed constructively, that is, in ways which are personally satisfying and socially acceptable. When we find individuals who, on the one hand, are behaving in ways which are ineffective and socially unacceptable or, on the other hand, whose behavior responses and interests lack reasonable balance and diversity—even though they be essentially acceptable—we should recognize the fact that we are dealing with persons who do not represent good mental health risks and in whom, given reasonable potentials, mental growth toward an adequate balance and adjustment, has not proceeded satisfactorily.



——Curve showing ideal normal distribution of interest-energy in personally satisfying, socially acceptable ways.

----Curve showing unhealthy distribution of interest-energy, where interest remains too closely related to infantile self—marked by such behavior characteristics as

Dependency, sensitiveness, emotional instability, day dreaming, fearfulness, shyness. and later Fears, phobias, feelings of inferiority, hypochondriacal complaints, social isolation, etc.

A—Infancy, early self-centered, auto-erotic period.

B—Pre-school period.

C—Transition period between home and larger social group, represented by school.

D—Pre-adolescent period.

E—Puberty—later auto-erotic period. Marked by self-consciousness, sensitiveness, slump in outside activities and performance, *e.g.*, school performance, and determined by physical changes of period.

F—Later adolescent years, with redistribution of interest to outside things—social interests, recreational and vocational interests, mating or hetero-sexual interests.

The emphasis of the public health program must be on the growth process, insuring so far as is possible conditions under which growth may proceed in a healthy fashion. The integration of a mental health approach implies that the personnel of health departments shall be familiar with: (a) the way in which mental growth proceeds; (b) the factors which favor and the factors which interfere with healthy mental growth; (c) behavior responses at all points in the developmental period or in the adult periods which suggest significant deviations from healthy mental growth or mental health; (d) the place of inheritance in relationship to mental disorder since much of the general public's fear and misunderstanding of mental disease is based on misconceptions of the part played by heredity; (e) the laws of learning. Inasmuch as it is impossible to project an adequate program of health education without some knowledge of how learning takes place, the emotional factors which are involved, the satisfactions, resistances, and fears which are aroused in the presentation of new material, and the adjustments of which are more important than the simple acquirement of new facts. For example, around such learning as has to do with the establishment of health habits in relationship to such functions as eating, sleeping, and elimination—public health teaching, in its desire to see these habits established for the growing child, has emphasized their importance to the point that a destructive over-concern and anxiety has been set up in the minds of parents.

In public health teaching we have frequently overlooked the learning principle that an accompanying emotional satisfaction is an essential for all good learning. The parent, in expressing anxiety and in the urgency to secure adequate health habits, may make around this training a battleground which not only defeats the immediate purpose of the teaching but which is a seriously interfering factor in other aspects of mental growth. Again because of their own unresolved conflicts, parents and other adults are frequently quite unable to use in a reasonable fashion the factual material which we might include in a health program. We have recognized in our approach to parent education or teacher education, the importance of helping these adults to some re-adjustment of their own attitudes and misunderstandings rather than just being satisfied with handing them factual information which they may or may not be able to use wisely.

SUMMARY

In this rather general presentation, dealing with the integration of mental hygiene in a public health program, I have attempted to indicate that:

1. Any program of public health and preventive medicine to be adequate must approach its problem with the premise that physical and mental aspects of health represent one single complex state of adjustment. That the individual in all his responses is a "reacting whole." Any program of therapy or prevention which does not adapt this approach lacks effectiveness and balance in much the same way as a boxer with one hand out of action.

2. The approach to mental disease prevention does not differ in any respect from the approach to general health and preventive medicine.

3. The emphasis in any program for mental health must be on safeguarding the "growth process." In guiding the process of mental growth, our objectives are: (a) emotional maturity in terms of emotional independence and emotional self-control; (b) intellectual maturity. Failure in securing through growth an adequate degree of emotional maturity leaves us with individuals who are poor mental health risks.

4. The public health group at the moment is in a vulnerable and at the same time in a strategic position. They cannot afford to

overlook an aspect of health effort as inclusive as that to which they have been giving the major part of their attention—at the same time they are in a position to make a contribution which promises more in the way of returns, over the next decade, than perhaps any other development in the social or medical fields.

The Impact of Science Upon Society

. . . But not alone economics: if the impact of science brings certain evils they can only be cured by more science. Ordered knowledge and principles are wanted at every point. Let us glance at three only, in widely different fields: man's work, man's health, man's moral responsibility. The initial impact of new science is in the factory itself. The kind of remedy required here is covered by the work of the National Institute of Industrial Psychology. Some of this improves upon past conditions, some creates the conditions of greater production, but much of it combats the evils arising from new conditions created by modern demands, speed, accuracy, and intensity. It invokes the aid of many branches of science. It is the very first point of impact. Yet its finance is left to personal advocacy, and commands not 10 per cent of the expenditure on research in artificial silk, without which the world was reasonably happy for some centuries. We can judge of the scope of this by the reports of the Industrial Health Research Board. Again, the scientific ancillaries of medicine have made immense strides. Clinical medicine as an art makes tardy, unscientific, and halting use of them. The public remains as credulous as ever, their range of gullibility widened with every pseudo-scientific approach. (We do not know what proportion of positive cases can create the illusion of a significant majority in man's psychology, but I suspect that it is often as low as 20 per cent.) For a considerable range of troubles inadequately represented in hospitals, the real experience passes through the hands of thousands of practitioners, each with too small a sample to be statistically significant, and is, therefore, wasted from a scientific standpoint.

Half-verified theories run riot as medical fashions, to peter out gradually in disillusionment. If the scattered cases were all centralized through appropriately drawn case histories, framed by a more scientifically trained profession, individual idiosyncrasy would cancel out, and mass scrutiny would bring the theories to a critical statistical issue of verification or refutation in a few months. This would be to the advantage of all society, and achieve an even greater boon in suggesting new points for central research.—Sir Josiah Stamp, The Impact of Science Upon Society, *Science,* Sept. 11, 1936, p. 239.

Recent Advances in the Control of Pneumonia*

RUFUS COLE, M.D., D.Sc.
Hospital of the Rockefeller Institute, New York, N. Y.

WITHIN the lifetime of the older members of this audience one of the principal causes of death in the English bills of mortality was "fever." Under this term were included not only typhus and typhoid fever but probably also many cases of meningitis and miliary tuberculosis, to say nothing of the various forms of paratyphoid, dysentery, and other acute infections of the intestinal tract. Although some progress in the prevention of certain of these diseases had been made before an etiologic classification was possible, it was only following the discovery of the causal agents that there occurred the great advances in prevention that are now hailed as triumphs of modern organized public health.

In the light of what has been accomplished in the control of the so-called intestinal infections, it is astonishing that almost no effect has been produced on the prevalence of acute respiratory diseases or on the associated mortality. Indeed, notwithstanding the vast army of health workers that has been mobilized to fight disease, and the expenditure of enormous sums of money for public health, there occurred only a few years ago, the greatest pandemic of acute respiratory disease that the world has ever seen, with an unprecedented loss in human lives. Each year in many regions there now occurs a greater loss of life from acute pulmonary infections than ever resulted from typhoid fever, even in the worst epidemic periods.

These facts deserve the most serious consideration of those guarding the health of the people. Is this condition due to lack of knowledge, to the indifference of health authorities, to ignorance of physicians, or to all of these factors combined?

In my opinion, a most important obstacle to progress in this field has been the employment of the term "pneumonia," which implies a specific infectious disease, but which really covers all forms of inflammation of the lungs. So long as "fever" was a reportable disease, no progress could be made in preventing typhoid and allied conditions. So long as the attempt is made to control "pneumonia," the results are bound to be futile.

For pneumonia is not one disease but is a group of diseases, each with a specific etiology. General sanitary measures could have and did have some effect in the prevention of diseases like typhoid and typhus. We know of no such measures that can influence acute infections of the respiratory tract, and all the efforts to decrease the prevalence of dust, to

* Read at a Special Session of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

diminish crowding, to prevent sneezing, to lessen susceptibility by consuming vitamins, by avoiding fatigue or overdrinking, have had little or no effect. The attack must be directly or indirectly on the specific infectious agents themselves.

As long as it was believed that pneumonia was due to pneumococcus, an organism widely distributed in nature, present in the mouths of the healthy as well as the sick, the problem indeed seemed hopeless. What could be accomplished in the way of prevention of intestinal infections if typhoid bacilli, all the paratyphoid bacilli, and the various kinds of dysentery bacilli were considered identical, and also identical with the colon bacilli inhabiting the intestinal tract of healthy persons? As a matter of fact all these microörganisms *are* closely related in form and function, and very careful laboratory procedures are required to differentiate them. The discovery, therefore, that pneumococci are not all alike, that there are a number of varieties and that those causing the most serious and most common forms of acute lung disease are not widely distributed, was of great significance.

A second great obstacle to advance in this field was raised during the last century following the development of pathologic anatomy and the introduction of methods of auscultation and percussion, when a classification of acute pulmonary disease on an anatomical basis was attempted, and the recognition of the various forms by the methods of physical diagnosis became the chief interest of physicians. If all the time that has been spent by doctors in efforts to determine the exact portion of the lungs involved in cases of acute pulmonary infections had been spent in detecting the etiologic agents concerned, many lives might have been saved. Even pathologists with the tissues before them, are in many cases unable to say whether the condition from which the patient suffered was broncho or lobar pneumonia. From the public health standpoint these anatomical diagnoses are not only useless but are misleading, for within very recent years in the English mortality tables the deaths ascribed to bronchitis are almost as numerous as those in which the diagnosis is pneumonia. A second great advance has been made, therefore, by the discovery of methods by which the causal agent in every case can be readily determined and the cases thus classified etiologically. It happens that these methods involve laboratory procedures, but let us remember that typhoid fever and the various forms of paratyphoid can also be differentiated only by laboratory methods.

It is impossible today to discuss in detail the matter of terminology, though this is of much significance, for as Faber has said, the physician "cannot live, speak, or act without the concept of morbid categories" and, we may add, no more can the public health worker. Even if it were desirable, it would be impossible to overthrow entirely the terminology now in use, but it would add greatly to progress if the term "lobar pneumonia" were confined to the designation of those cases of acute lung infection which present the clinical features that have been considered characteristic, and in which the etiologic agent is pneumococcus. The particular variety of the disease may then be designated by the type of pneumococci concerned and Type I pneumonia becomes the name of a definite and specific disease, as specific as is typhoid fever. Since Type I pneumonia and Type II pneumonia together constitute 60 per cent or more of all cases of lobar pneumonia, they present the outstanding immediate

problem as regards control of this group of diseases.

A further great advance in knowledge has consisted in the discovery that not only can animals be highly immunized against pneumococci of the same specific type, but that the serum of these artificially immunized animals, when injected into susceptible ones, may render the latter resistant, and still more important, if injected promptly and in large amounts into animals that have already been infected will cure them.

Another advance in knowledge has consisted in the discovery that pneumonia is rarely a primary disease. During the World War when acute respiratory diseases were so prevalent, it was found that most cases of pneumonia followed or were associated with measles or influenza. Experience since then indicates that in most cases of pneumonia the onset is preceded by a cold of longer or shorter duration, or by influenza-like symptoms. The sudden onset of pneumonia in a person previously perfectly well is only another textbook fairy tale; in my experience it rarely happens in real life.

Dochez and his collaborators have shown that colds, at least those of certain varieties, are due to filterable viruses, and Laidlaw and Andrews in England, and Francis in this country have similarly presented evidence indicating that filterable viruses are also responsible for influenza, at least for that occurring in interepidemic periods. Francis has also developed methods by which active immunity in man to the influenza virus can probably be produced.

Now, how can all this new knowledge be used in attempts to lessen the ravages of acute pulmonary infections? The first step in all efforts of this kind must consist in detecting and diagnosing each individual case and thus determining the frequency of occurrence of cases of the various kinds. Paraphrasing a remark of Benjamin Wood, " Pestilence must not walk in the dark. It must be measured and registered and walk at last in the open day." The methods for accomplishing this in the case of the acute respiratory diseases are now available. It remains for physicians and public health authorities to employ them.

Efforts at prevention may be directed toward the chief predisposing factor, in this case the preceding upper respiratory infection, or toward limiting the spread of the infectious agent itself, or, in lieu of this, rendering the population immune by means of artificial immunization. While the discoveries that colds and influenza are due to filterable viruses, are of great significance, methods for applying this knowledge in the prevention of these conditions have not yet been established.

It is possible, however, to prevent the spread of pneumococci from the sick to the well, at least in Type I and Type II pneumonia. It is now known that organisms of these types are not widely distributed. They are present in the mouths only of those suffering from pneumonia of the respective types except occasionally in the mouths of persons closely in contact with these patients, and then for only short periods of time. They may also occasionally be isolated from objects in the immediate surroundings of patients, or from the dust of rooms occupied by them. These facts and the results of studies of family and local epidemics indicate that Type I and Type II pneumonia are usually spread by direct transfer of the infective agent from the sick to the well.

Prevention of the spread of typhoid was long delayed by insisting that typhoid fever was an infectious, but not a contagious, disease. We must begin

to recognize that Type I and Type II pneumonia also are contagious diseases. It is true that isolation of patients has not been the measure principally responsible for the prevention of intestinal diseases; yet it is possible to limit and even stop the spread of typhoid fever by early diagnosis, isolation of patients, and careful disposition of all excreta. This was clearly demonstrated by the State Board of Health in Michigan in 1901, and by Koch in early studies carried out in Trier. More than 20 years ago at the Hospital of the Rockefeller Institute we began isolating all cases of pneumonia, disinfecting all sputa and other excreta, and insisting that doctors, nurses, and all persons coming in contact with these patients wear masks and gowns. It is not likely that masks form an effective barrier to the spread of infection, but they serve as a constant reminder to everyone that at least certain kinds of pneumonia are acute, specific, infectious, contagious diseases.

At present no conclusions can be drawn with regard to the effectiveness of artificial immunization. Few extensive experiments have been made with this method and they have been complicated by extraneous factors. The outlook in this direction is by no means hopeless but at the present time the chief reliance in the field of prevention must be placed on isolation of the patients.

On the other hand, it is now quite certain that much may be accomplished in reducing mortality from the severe pulmonary infections by suitable treatment. In the hospital with which I am associated, we have studied during the past 25 years, practically all forms of nonspecific treatment which offered any prospect of being valuable. Certain measures, such as the administration of oxygen and drugs to relieve special symptoms, have been found valuable, but even if employed with all possible skill, it does not seem that they can have a very marked effect in reducing mortality rates.

The situation is quite different, however, as regards specific treatment. During 1911 and 1912 extensive clinical and experimental studies on pneumonia were conducted in the Hospital of the Rockefeller Institute. It became evident that serum treatment of Type I pneumonia would probably be useful, provided the serum were given early and in large amounts. A horse was immunized against Type I pneumococci and serum was collected. On January 18, 1913, Ernest Schaffhouser, a sailor suffering from Type I pneumonia of 2 days' duration, was admitted to the hospital. The same day at 2:30 in the afternoon, 100 c.c. of the immune horse serum were injected into a vein of his arm. Two hours later he said he felt much better; the symptoms were obviously improved. Eight hours after the first injection he was given a second one of the same size. The next morning his pulse and temperature were normal; he was well. To make the cure certain he was given a third similar injection. Twenty-three years ago this was heroic treatment!

From that day to this practically every patient suffering from Type I pneumonia admitted to this hospital has been treated with serum, always insisting that the serum be type specific, that it be given as early as possible, and that it be administered in large amounts. In certain other places various subterfuges have been employed in order to avoid strict adherence to these principles. Serum has been given in small doses; it has been given indiscriminately to patients with pneumonia regardless of type; polyvalent serum has been used; great efforts have been made to reduce the amount of fluid injected, by employing

extracts or concentrates said to be 20 or 30 times as active as whole serum. In spite of all these substitutions and neglect of the underlying principles, however, convincing evidence has gradually been accumulated by various observers which shows that Type I serum is curative, and fortunately the day has now passed when it is necessary to urge this point.

It is not sufficient, however, that patients be simply treated by the administration of Type I serum; of great importance is how they are treated. As the animal experiments indicated, treatment should be commenced early, and prompt diagnosis is therefore of great importance. In my opinion physicians have made the diagnosis of pneumonia too difficult. They too frequently wait for the physical signs of consolidation to appear. As a matter of fact, to the experienced observer, the symptoms at the onset of the disease are almost pathognomonic. Most patients *threatened* with pneumonia *have* pneumonia. When, either with or without preceding respiratory symptoms, the patient has a chill, fever over 102°, cough, sharp pain in the chest, rapid respirations, and above all when the sputum is blood tinged, this person in the great majority of cases, has pneumonia. In all such cases the sputum should be examined without delay, and if pneumococci are present, particularly if they are of Types I or II, there can be little doubt about the diagnosis.

The laboratory worker should consider the examination of the sputum an emergency measure. It should not be delayed until the next morning or until other work is out of the way, and the physician should be notified by telephone or telegram immediately after the diagnosis is made.

As soon as it is determined that the patient is suffering from Type I pneumonia, serum should be administered. There should be no waiting to see whether the patient will not be better in the morning; it should not be delayed because he does not seem sick enough to justify giving serum; or it should not be decided that "it is too late," that "he is too far gone for serum to be of any use."

The only exceptions we have made in administering serum have been in an inconsiderable number of children who were not very ill, since most children with lobar pneumonia recover; second, in patients who were moribund on admission and died before the serum could be administered; and third, in patients who were obviously in the stage of recovery when admitted.

All other cases have been treated as soon as the diagnosis was made. This is of importance because some of those employing serum have recommended that it be used only in cases that can be treated as early as the 3rd or possibly the 4th day. It is true that the earlier in the disease it is used, the greater is the effectiveness of the serum, but our experience indicates that no patient, however late he is seen, should be deprived of the benefits of this measure. In our series, the mortality rate in cases treated during the first 3 days was 4.8 per cent, in those treated on the 4th day or earlier, 8.2 per cent, on the 5th day or earlier, 8.6 per cent, and in those treated after the 5th day 19.5 per cent.

Until 3 years ago, whole serum in doses of 100 c.c. was administered; since then concentrated serum has been employed, not in doses of a few c.c., but in 15 to 30 c.c. doses. The greater ease of administration of the concentrated serum is obvious. In addition, the frequency of immediate and febrile reactions is probably less. Probably the greatest value in using the concentrated serum consists in a decrease in

frequency and severity of the symptoms of serum disease. With present knowledge, however, there is no way in which these unpleasant but harmless symptoms may be completely avoided. After all, in a very serious disease like Type I pneumonia, from which, unless serum be administered, 1 patient in every 4 dies, a few days of itching of the skin and pain in the joints is not too high a price to pay for restoration to health.

The complaint is sometimes made that after all, serum treatment is possible in only a part of the cases of pneumonia, and attempts are made to treat all cases of pneumonia, either with Type I serum or with so-called polyvalent sera. One might as well argue that it is useless to treat patients suffering from diphtheria with serum, because this treatment is not also effective in cases of malignant streptococcus sore throat.

Much stress has been laid upon the possible dangers of violent reactions. There are some risks but we now know how to avoid them. That disastrous results did not occur when we first began using very large amounts of serum intravenously, when we did not know the dangers or how to guard against them, shows that the dangers are not too great. By making preliminary tests for serum sensitiveness, by proceeding very slowly in the first injections, and by prompt use of adrenalin in case any symptoms occur, the possibilities of serious complications are almost entirely avoided.

Opinions differ as to the effectiveness of Type II serum. Our own early experience was not very favorable and we decided to give our entire attention to the treatment of Type I cases. The more recent statistics are a little more promising. It is possible that this serum may still be improved, and where the very best serum is available it is even now justifiable to employ it in the Type II cases. On the other hand Type III pneumococci differ so fundamentally in their immunological properties from pneumococci of Types I and II that at present it does not seem advisable to attempt to treat patients suffering from Type III infection, with serum.

The pneumococci previously designated as belonging to group IV have now been divided into a large number of types, which have been numbered consecutively from V to as many as XXXII, and there may still be others. Certain pneumococci of these types, notably V, VII, and VIII, have been found to be responsible for a not inconsiderable number of cases of lobar pneumonia, though of course relatively a small percentage of the total cases. Sera have been produced by several commercial firms and public health laboratories against pneumococci of certain of these types. Especially in Type VII and Type VIII pneumonia a considerable degree of success in treatment has been obtained, though the experience is still too limited for final conclusions to be drawn. At present the main dependence must be placed on treatment with Type I serum, and since the number of Type I cases is so large and the serum so effective, the saving in human lives by the proper use of this form of treatment is bound to be considerable.

In the light of the evidence which I have briefly presented it seems that public health authorities are not only justified in attempting to limit the spread and decrease the mortality resulting from acute pulmonary infections, but that it is their duty to do so.

To be effective this work will require extensive organization and continuous effort and it will demand the coöperation of physicians with the health organizations. The campaigns now being

conducted in Massachusetts and New York State are providing experience as to the best methods of procedure. The campaign cannot be merely one of education. Active steps will have to be taken by public health authorities and these must consist, (1) in providing laboratory aid so that all cases may be accurately and promptly diagnosed; (2) in arranging for the proper registration of all cases and in carrying out epidemiologic studies; (3) by educational measures providing for proper isolation of patients; (4) supplying serum that is of maximum strength; and (5) assisting in the prompt and proper administration of the serum.

Too much must not be expected immediately in the way of decreased incidence and lowered mortality rates. Years of effort have been required to control typhoid fever and diphtheria. Such campaigns, like avalanches, gather momentum and increased power as they proceed. The institution of efforts by public health authorities will spread information concerning these conditions among the medical profession and the laity, will lead to increase of knowledge concerning the epidemiology of the disease, and will stimulate investigation into the details of the infective process and of the nature of immunity. It is indeed on the results of these investigations that we must ultimately depend for methods which will permit the complete control of this group of infections. Let us hope that the public will give the needed support; and may the time be not too distant when the deaths from "pneumonia" as recorded in our statistics will be as infrequent as are now the deaths from "fever," when as few persons will die from Type I pneumonia as now die from typhoid, and when we can look back at the triumph over acute pulmonary disease with the same satisfaction with which we now regard the victories over acute infections of the intestinal tract.

Using the Truth We Have

NOTHING in science is more laborious than the clarification of the factors which influence health. Human environment is so complex, man himself is so complex, and his powers of modifying himself to suit altered situations so great that it is only by prolonged observation and experiment, constantly evaluated, that we ever approach the truth. This, however, is no excuse for not using the truth when we have got it. Here indeed we may justly complain; but let us be sure that the fault does not lie with those who are able to use the truth.—Dunstan Brewer, D.P.H., *Ann. Rep., Medical Officer of Health for the Year 1935,* Borough of Swindon, p. 8.

Recent Advances in Administrative Technics*

HENRY F. VAUGHAN, Dr.P.H., F.A.P.H.A.
Commissioner of Health, Detroit, Mich.

WE convene annually as Fellows and Members of the American Public Health Association because we have chosen as our life work the profession of sanitary science, dedicated to the improvement of the health, welfare, and happiness of mankind. Of no group can it be more truly stated that it is the combined product of heredity and environment and, like most humans, we find ourselves blessed with kindly and helpful characteristics but at the same time burdened by obsolete and ill-founded theories and practices. Fortunately, in our case, the inherited concepts may be cast aside without awaiting a new generation.

Early health programs considered the whole community because they were environmental. Witness the elimination of the exotic plagues of typhus and cholera, and the rapid control of typhoid and other filth-borne and water-spread diseases. The intermediate era concentrated efforts on the common communicable diseases, and made programs in terms of the lowest group in the community. This period was short-lived and disappointing because of the failures in quarantine and isolation, and the unwillingness of disease as well as physical and mental imperfections to recognize any class, social or geographic distinctions. Present-day plans must consider all classes because education and not service is the basis for work.

There is an ever-changing philosophy of the administration of public health. Health departments were born in the nauseating, offensive airs and vapors of the open sewer which gave forth its lethal gas; in the miasmal emanations from the deadly swamps and marshes; in the esthetically disagreeable associations of the garbage dump. But today, well beyond the life giving age of 40, we find many a public health department still smugly complacent and making little or no effort to extract the public health budget from the garbage fund. We who become self-satisfied and unwilling to travel with the tide of scientific progress, are doomed to destruction. Public opinion and smartness will rapidly expose our weaknesses, and demand for the advantages of modern health service will force our retirement. We have bemoaned the want of opportunity and the lack of funds, but the increasing availability of federal funds through the U. S. Public Health Service and the Children's Bureau now presents a potent challenge.

The outstanding need is for the establishment in every local area, whether city, county, or district, of a full-time public health service under the direction of a health officer sympathetic

* Read at a Special Session of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

to the viewpoint of community-wide participation, one who can understand the advantages of weaving into his program the more or less latent potentialities to be found in the lay, the professional, and the teaching groups. Not only should the health officer be a man of experience and training, but his responsible subordinates should have a corresponding training in their special fields of activity. There should be, in addition to the public health administrator, the necessary professional, technical, public health nursing, engineering, laboratory, and educational assistance. The lack of funds, as well as the want of lay appreciation of the results to be obtained, has prevented more rapid progress, but now, with the assistance of the federal government and the states, local health organizations are being developed more rapidly. At the end of 1935 the U. S. Public Health Service reported that 612 counties in 32 states had whole-time county or district health services, an increase of 71 units over 1934. During 1936 progress has been more marked, and states like North Dakota, Wisconsin, and Indiana, have established their first county health units with the aid of state and federal funds. Available records in the Surgeon General's office as of July 1, 1936, indicate a total of 820 counties under full-time health service, distributed among 39 states.

The health commissioner as the administrator and leader is the key man in the community health organization. The responsibility demands real leadership. Not only must the health officer possess a basic training in public health science and a willingness and ability to work effectively with lay and professional groups, but he must also possess at least two essential characteristics:

The health director must have the ability to study and see clearly his own program in relation to local problems and needs, to the end that his program will develop the most effective use of personnel and funds at his command. While it is true that there are certain fundamental essentials to all well balanced public health programs, there has been too great a tendency to standardize, to routinize local health programs, especially in methods of approach in health education and in the provision of preventive medical services for individuals at various economic levels. Too many health officers adopt a certain type of program simply because someone else has that type of program. Some of the outstanding health departments of this country—Milwaukee, Baltimore, New Haven, and Syracuse—have been successful because they have not followed the other fellow's plan but rather have developed their own in the light of their own problems and possibilities. Let us not forget that local problems and local possibilities are not necessarily synonymous.

Educational groundwork must precede corrective action, especially when the pocketbook is affected. Surely, no individual desires to die prematurely, and no sane person wishes to be responsible for the death of another. Nevertheless, the health officer who boldly invades a community which has not benefitted by an educational program establishing in the lay mind the relation between impure milk and the death of babies, will literally be driven from his home and family if his first official act is to require universal pasteurization of milk. The need of this safeguard is apparent to every sanitarian, but the health official must not travel too far ahead of public opinion, especially when local pride is affected. Contrariwise, the health officer who questioned the desirability of 100 per cent pasteurization in Boston or Cincinnati would be guilty of official suicide.

Capable leadership on the part of the health officer involves the development of services which, with the exception of research work, will show measurable, demonstrable results within a reasonable period of time.

The health director must have the ability to develop a morale—an *esprit de corps,* in his own organization. He should be able to imbue his personnel with the feeling that each individual's work is important and worth doing and that each who does his or her work well will find self-satisfaction in the knowledge that his work has added materially to the health and happiness of the people of his community. There is nothing sadder than the public health nurse or sanitary inspector who sees nothing but a day's work in his job. The health officer who is a leader should supervise, guide, and stimulate, but at the same time permit the free play of each individual's own creative ability. Thus is real progress achieved. Frequent staff conferences are especially helpful in the development of teamwork. An outstanding medical school is directed by the teamwork of a qualified faculty rather than an autocratic dean. Group thinking among executives which comes from discussion prevents individuals from carrying on little shows of their own which are inimical to each other and preserves a solid front to the public. The entire health department personnel should be kept informed regarding the major objectives to be obtained. Incidentally, the administrator may then rest assured that the general policies, understood by all his staff members, will be continued while he is absent on vacation.

The health education program should be built around the soundness of the department's policy and not around the fanfare and ballyhoo of the health officer. The late Enion Williams, for many years the distinguished health commissioner of the State of Virginia, was asked to what he attributed his long tenure of office. The reply was to the effect that he had always submerged his own personality and name in an endeavor to establish a widespread public confidence in the work of the State Health Department.

While, with the expansion of human interest in disease prevention, there has developed an increasing willingness of individuals and communities to support health organizations, there still remains the need of conserving to the utmost the relatively limited funds which can be expended in this field. Frequent, well thought out tests of the effectiveness of procedures are becoming more common each year. While the cause of public health is being aided measurably by the availability of Public Health Service and Children's Bureau funds, we should bear in mind that these funds will quickly "dry up" unless we not only make effective use of them but also show an increasing willingness to assume locally our fair share of financial responsibility for providing essential health services. On the other hand, we cannot expect adequate local financial support until specific local health education has been successful in persuading a substantial portion of our people that public health protection is worth purchasing.

We have long complained of the lack of trained personnel and have too frequently been satisfied with employment of mediocre and unprepared assistants, many of whom have been thrust upon us by political pressure. Our fellow health workers employed by the non-official agencies not infrequently look down upon the official health department personnel with a certain degree of scorn and, unfortunately, in too many instances there has been justice in the assumption of such an attitude. Low requirements and standards establish a

low level of service in public agencies. Now, do not misconstrue my meaning —I am not directing these remarks at all health departments. Nevertheless, every one of us has knowledge of the existence of conditions such as I mention.

In the employment of public health nurses some health officers seem to take the attitude that the completion of a hospital training course involving its hours of drudgery and maid service qualifies any nurse to enter the field of health education. We need something more than the reception of a new recruit, welcomed by a broad administrative smile, and waved with the friendly thrust of a shoulder into the adventurous field of family education. The National Organization for Public Health Nursing has striven diligently to impress us with the need of employing trained personnel. The very least that we, as health officers, can do is to strive toward their excellent standards as a goal. In most communities the early adventures in promotion of health education through the employment of public health nurses were started by the ever alert private agencies who saw the possibilities of reducing the tuberculosis death rate; of cutting down the high mortality of infancy; of establishing safeguards for the expectant mother; and, in general, carrying the message of good health to the public. Quite properly, as time proceeded and as there was engendered in the public mind a consciousness of the value of these services, cities and counties assumed their rightful responsibility and began to employ nurse-educators. In so doing we have not always adhered to the standards set by our predecessors.

Now we are faced with that golden opportunity, offered by the Public Health Service through regional schools of public health to strengthen the training of our present personnel, employ the qualified health educator, statistician, laboratorian, and public health engineer. Incidentally, it is more economical to employ young sanitary engineers rather than untrained politicians as health inspectors. The turnover among them is greater but they bring a freshness to the service which prevents it from becoming perfunctory. The same is true with other trained personnel.

It is ill advised for the health officer to isolate himself from community interests, especially the medical profession. Unwarranted suspicions have developed on each side. Recognizing the desirability of family-physician participation in a community health and welfare program, it is essential that every private physician should be thoroughly conversant with the newer technics and procedures which aim to prolong human life. He must familiarize himself with the technics for diphtheria protection, with current knowledge regarding whooping cough and scarlet fever; he must be well acquainted with the tuberculin test and the roentgen findings which reveal suspicious tuberculosis; he must know the syphilis problem; he must be alert to the significance of the abnormalities which lead to cancer, cardiac disease, and the degenerative diseases of middle and late life. Briefly, he must be conscious of the part he can play in discovering such imperfections in human life, and provide the means of their prevention or alleviation.

In spite of the remarkable reduction in death rate, tuberculosis causes 3 times the deaths of all common communicable diseases in children, and retains first place on the mortality tables in young adult life. We recognize the value of such community facilities as clinics, both diagnostic and treatment, hospitalization of infectious cases, provision for open window and

open air schools, camps and preventoria, control of sanitation and milk pasteurization; but we can truly hide our faces in shame when we examine our case finding facilities. The *Appraisal Form* of our Committee on Administrative Practice offers a perfect score if 20 per cent of notifiable cases are minimal. I venture the opinion that not half a dozen major cities have even reached this goal. Are we to remain complacent when 4 out of 5 of all tuberculosis cases first coming to our attention are moderately or far advanced? We could never expect to arrest the progress of a typhoid epidemic if we knew only of the dying cases.

Our tuberculosis case finding and epidemiological services are still of a primitive character. We are losing an opportunity to render efficient service to the public through prompt isolation; we fail to serve the patient with modern treatment and we fail to enhance his opportunity for complete recovery and return to usefulness as a wage producing citizen; we continue the extravagant expenditure of public funds to hospitalize the advanced case. The period of hospitalization and the cost to the individual or taxpayer can be halved by finding the minimal case rather than delaying until the patient has developed tuberculosis in a more advanced stage.

Why not boldly endeavor to increase the proportion of early cases to at least two-thirds of those reported to the health department? Save the dollars in our hospital budget by expending one-tenth the sum in the preventive technics of early case finding. How better can this be accomplished than through the coöperation and participation of the family physician? It is he who most frequently observes the early signs of disease and, he must become conscious of the central part which he must play in the tuberculosis as well as all other phases of the preventive medicine program. First, he must realize that early diagnosis requires a tuberculin test and roentgen examination of the chest. Night sweats, cough, fever, loss of weight or appetite, and hemorrhage are not diagnostic of minimal cases. Then, he must share with the health department the responsibility of searching for and examining contacts to known cases of tuberculosis; in routinely testing school children of a selected age or grade; in systematically canvassing certain geographic and racial groups among whom tuberculosis presents an unusual problem. The office of the practising physician must become a House of Health, closely linked directly as well as indirectly through the local medical society with the health department. Such office is a health center to which the layman may go with confidence that he and his family will receive the full advantages of modern medicine. The alert physician will not overlook this unique opportunity to spread the gospel of personal hygiene and utilize the recognized technics of health education.

Postgraduate medicine is no innovation, but the establishment of refresher courses in preventive medicine is rather a new development. Such undertakings have been sponsored in recent years by the W. K. Kellogg Foundation, the Commonwealth Fund, certain state health departments—notably those of Massachusetts, Mississippi, and Virginia — Vanderbilt University, the Michigan State Medical Society, the Detroit Department of Health, and other organizations. Their influence in promoting child health through the family physician is now well recognized. Unfortunately, however, there are many physicians, especially in the large cities, who are not wont to attend post-

graduate courses. They do not belong to hospital staffs nor are they members of the local medical society. The layman, in his ignorance, may not discern between the qualified coöperating doctor and the one who practises in the shadow-lands of pseudomedicine.

It behooves the health officer to see that each licensed physician is thoroughly conversant with the plans of the public health program and has learned the technics and the interpretations of the medical services. A medical coördinator to cultivate the relations with professional groups, to visit physicians and dentists in their own offices, to demonstrate there, as well as before society meetings, the significant tests, to carry the educational program into undergraduate medicine, is becoming an urgent need for every modern health department. In small organizations the health officer may serve in this capacity; in a large city there should be a full-time deputy commissioner appointed as director of medical relations. Such an individual has just been chosen for the Detroit Department of Health. We expect through his aid to stimulate an ever increasing interest in the practice of preventive medicine by the family physician.

In order that the advantages and the availability of these services may be known to the laity, it is essential that public health departments and allied organizations conceive and conduct well designed and executed programs in health education. The tools of popular health instruction, involving the spoken or printed word, the radio, printed literature, talks before various lay groups, and other technics too numerous to mention, have been effectively employed in innumerable instances. In addition to this, there is need for more intensive use of trained personnel in the field of individual health education. For this purpose the well trained public health nurse can be of great service. Evidence of the effectiveness of this type of coöperation is found in every modern health organization.

In those communities where sympathetic health officer and medical profession coöperation is forthcoming there is evidence that services are being dispensed in an ever increasing quantity by the family physician. For example, in the city of Detroit, all the diphtheria prevention treatments are being given by the family physician and three-fourths of these are being paid for by the parent. Each year the percentage of preschool children protected has increased until now 60 per cent are known to have received such service. In 7 * typical rural counties in southwestern Michigan the county health departments, in coöperation with the W. K. Kellogg Foundation, have established the most highly developed participation program with the physicians, dentists, school teachers, and other local educational facilities. Here it may truly be said that professional men are conscious of the opportunities of preventive medicine and the public is being taught where to secure the advantages of such service. There seems to be an increasing appreciation on the part of parents that preventive medicine is a purchasable commodity and that when the family purse will permit, it should be purchased the same as any other essential of life, such as food, fuel, or shelter.

I fully realize that I have added nothing particularly new in the field of administration technics, but I have endeavored to re-assemble some of the opportunities which we possess to strengthen and enrich our community health services with a view to increasing the health, welfare, and happiness of mankind.

Bacterial Limitations in Ground Fresh Meat

WALTER C. ELFORD

Chief, Pure Food and Sanitary Division, Bureau of Health, Portland, Ore.

DURING the fall of 1933 we sought to determine the bacterial value in testing the wholesomeness of ground fresh meat, especially hamburger.

This was occasioned by the fact that numbers of people were complaining that this type of food, which they had purchased, was off flavor, if not actually spoiled. Our city ordinance provided penalties for the selling of "unwholesome" food. We were, however, handicapped by difficulties found in defining the meaning of "unwholesome." One case involved the need of expert testimony which we could obtain only at considerable expense. The experts themselves were put to considerable trouble as two of them had to travel between 50 and 75 miles, losing time which could hardly be compensated for by money. It was certain that such a method could not be made practical.

The ground meat, or hamburger as it was called, involved in this case, showed a bacterial count of 85,000,000 per gm. It was unquestionably bad. The court so found and levied a fine of $50.

It could be plainly seen from this that if we were to cope successfully with this problem some simple method must be devised. The question confronting us was this: Was there a certain bacterial development which could be depended upon as indicating a generally recognized state of unwholesomeness? Our tests appeared to show that there was.

COLLECTING SPECIMENS

The method employed in collecting the evidence was very ordinary. Specimens were obtained by inspectors by purchase, it having been decided that this presented the true side of the problem as it affected the consumer. When questionable delay was involved, specimens were packed in ice until delivery to the laboratory. This, however, only involved those taken at considerable distances or in a way that might raise an issue.

There was a tendency on the part of some merchants to prepare the sample. This was objected to, the inspector insisting upon the delivery of that displayed for sale.

It was thought advisable to inform merchants of the purpose of the purchase. This enabled them to take specimens for themselves, which many did, for the purpose of "comparing tests." Whether they had such tests made or not we were unable to learn, except in a very few instances. It appeared, however, that all were satisfied with our findings, as no protests appeared. Each merchant was notified as to findings as soon as the specimens from his place had been examined.

LABORATORY TECHNIC

The procedure for evaluating the number of bacteria was as follows:

1. The ground meat specimen received at the laboratory was in the same wrappings as used in delivery to the public.
2. The entire sample was weighed. Ten grains were transferred to a 90 c.c. sterile water blank with a sterile spatula. Care was used to get as complete a cross-section of the sample as possible.
3. The blank was then shaken vigorously for 30 seconds. Two dilutions were made from the original 1 to 10 dilutions, 1 to 1,000. and 1 to 100,000. From the latter, plates were poured, with additional plates with 0.1 c.c. of the 100,000 dilution, giving check plates of 1 to 100,000 dilution.
4. The plates were incubated for 48 hours at 37° C.

The media used were plain nutrient agar. An index of the laboratory results is shown in Table I.

TABLE I

RESULTS OF BACTERIOLOGICAL EXAMINATION OF SPECIMENS OF HAMBURGER, OR GROUND MEAT COLLECTED FROM MEAT MARKETS

Sample No.	*Bacteria per Gm.*	*Sample No.*	*Bacteria per Gm.*
1	300,000	21	100,000
2	200,000	22	3,800,000
3	9,800,000	23	10,000,000
4	5,400,000	24	100,000
5	600,000	25	3,500,000
6	600,000	26	700,000
7	1,000,000	27	1,200,000
8	600,000	28	3,600,000
9	700,000	29	5,000,000
10	1,200,000	30	2,100,000
11	1,500,000	31	300,000
12	9,500,000	32	20,000,000
13	3,200,000	33	3,800,000
14	1,700,000	34	5,000,000
15	4,500,000	35	500,000
16	7,200,000	36	100,000
17	400,000	37	400,000
18	6,200,000	38	4,500,000
19	2,100,000	39	800,000
20	900,000	40	700,000
		41	4,800,000

As soon as possible after the bacterial count was certified the meat market was notified. Where the count was above 10,000,000 per gm. a communication accompanied the count explaining our position relative to the high count. The result was without exception a very noticeable improvement. Bacterial counts were less in number and the ground meat was much improved in quality.

A few of these results are shown in Table II. This is, however, only part

TABLE II

SHOWING DECREASE IN BACTERIAL COUNT FOLLOWING NOTIFICATION OF EXCESSIVE COUNT

Establishment No.	*Bacteria per Gm. Original Specimen*	*Bacteria per Gm. Following Notice*
4	32,000,000	1,600,000
5	21,000,000	6,000,000
7	13,000,000	2,800,000
9	19,000,000	500,000
10	10,000,000	2,800,000
12	18,000,000	8,000,000
14	17,000,000	4,000,000
15	15,000,000	900,000
16	16,000,000	1,100,000
19	19,000,000	600,000
20	19,000,000	300,000
21	26,000,000	1,800,000

of the picture. Subsequent counts showed a continued improvement. For instance, in the case of establishment No. 5, the count decreased on successive specimens, taken several days apart as follows: 1st, 21,000,000; 2nd, 6,000,000; 3rd, 1,700; and 4th, 700. This was similarly repeated in No. 12: 1st, 18,000,000; 2nd, 8,000,-000; and 3rd, 100,000; and again in No. 21: 1st, 26,000,000; 2nd, 1,800,-000; and 3rd, 300,000.

AN ORDINANCE NOW IN FORCE

Such showings as these made it possible for us to go before the City Council and ask for an ordinance fixing a bacteria count for determining the wholesomeness of hamburger, or ground fresh meat.

This ordinance reads as follows:

Unlawful Bacterial Content of Ground Meat—It shall be unlawful for any meat market to hold, sell, or offer for sale any hamburger or fresh unseasoned ground meat the average bacterial count of which exceeds 10,000,000 per gram. The average bacterial count shall be deemed to mean the logarithmic average of the bacterial counts of all samples taken during a period of not less than 4 days, and including at least four samples taken on separate days.

It is gratifying to say that we have not found it necessary to prosecute a single case for violation of this standard for the reason that we have never been able to get 4 successive high counts in the 2 years and 6 months the ordinance has been in effect. Notices of high counts are always followed by improvements in line with that shown.

Mosquitoes In Aircraft

A GOOD deal has been said and written upon the carriage of insects, and particularly mosquitoes, in aircraft.

In connection with yellow fever, the general opinion appears to be that there is very little risk of the carriage of infected mosquitoes by this method. At the International Health Conference, held at Cape Town in November, 1932, ". . . it was agreed that the risk of transporting mosquitoes in an infective condition is comparatively small, and can be met by the simple measure of de-insectisation of aeroplanes. Aedes may travel by trains or motors with equal facility. . . ."[1]

The majority of authorities on the subject have referred to this simple measure of de-insectisation. The method is simple, but its application in the ridding of an aeroplane of all insects definitely is not.

That "Aedes may travel by train or motors with equal facility" may be true; but would they travel as far in, say, four hours as they would do by aeroplane? In Africa, neither trains nor motors normally travel 300 or 400 miles without a stop, nor do they usually travel with doors and windows closed. In trains and motors mosquitoes have almost uninterrupted opportunities for escaping. It is not so in aeroplanes, from which escape is only possible at stopping places hundreds of miles from the starting-point.—*Quart. Bull. Health Organisation of the League of Nations*, V, 1:81 (Mar.), 1936.

Diagnostic and Immunological Tests of Rabies in Mice*

LESLIE T. WEBSTER, M.D.
The Rockefeller Institute for Medical Research, New York, N. Y.

THIS report deals with a method for diagnosing rabies by inoculating suspected material into mice and with tests for evaluating antirabic vaccines in mice.

Recently interest in rabies has become widespread. Public health authorities note an apparent increase in prevalence of the disease in animal species and recognize its consequent threat to man. Methods to control its spread in dogs have not, in most localities, met with conspicuous success. The effectiveness of canine preventive vaccination as now practised is questioned, and doubt is cast as to which of many methods of treating humans following exposure is preferable. Moreover, laboratory workers with new knowledge of viruses seek further data on rabies as the outstanding example of a virus disease in which immunization can supposedly be secured by a non-living vaccine, and in which the virus agent spreads in the body presumably along the nerves. A renewed study of rabies is timely, therefore, both from theoretical and practical viewpoints.

A review of experimental work on rabies brings out at once a fundamental and well recognized difficulty, namely, the lack of a test animal and a technic insuring quantitative results. If animals are inoculated with rabies virus in a manner approximating nature, their individual responses in general are irregular and difficult to measure, while if they are inoculated with large doses directly into the brain in order to eliminate these variations, all are usually overwhelmed. For example, when batches of animals are injected with material for diagnosis, irregularities of incubation period are encountered. When vaccinated and non-vaccinated animals are compared for resistance, any differences which may be present are masked if the test injection is made directly into the brain, and are difficult to measure if the injection is made peripherally. Due to inadequate methods of investigation, many problems in rabies remain unsolved.

The technical difficulties have now been overcome in part by finding that special strains of mice bred for susceptibility to virus infections are 10 to 100 times more susceptible to rabies than other laboratory animals per gram of body weight. One one-hundred-millionth gm. of mouse brain virus is fatal to at least 50 per cent of these mice when injected intracerebrally; larger quantities are practically always fatal. Injected into the tongue, cheek, thigh, or subcutaneous tissue, 1/10,000 gm. or more is similarly fatal. The peri-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 20, 1936.

toneal route, however, is somewhat less effective. These mice, therefore, become the animals of choice in the experiments now to be described.

A diagnostic test by mouse inoculation was developed [1] as a possible aid to the Negri body method. Sterile bits of Ammon's horn of the suspected case of rabies are emulsified in distilled water to make a 5 to 10 per cent suspension; 0.03 c.c. of this is then injected intracerebrally, and 0.25 c.c. intramuscularly into each of 6 Swiss mice. One animal is sacrificed on the 5th, 6th, and 7th days respectively and their brains examined for Negri bodies. The remaining 3 are observed for 4 weeks for signs of rabies. When prostrate, they are sacrificed and searched for Negri bodies.

Forty dog brains received by a city department of health have been tested. In 32, no Negri bodies were found and the inoculated mice remained well. In the remaining 8, a positive diagnosis was confirmed within 10 days by animal inoculation.[1] Brains of 28 supposedly normal wild animals have likewise been tested. Three of 9 skunks were positive by the mouse inoculation test. This brief experience suggests that this diagnostic tool may aid in the more accurate determination of the foci of rabies, together with its amount and spread in a given community.

The immunizing value of commercial antirabic vaccines has been studied by using a mouse serum-protection test and a mouse resistance test. The serum protection test was employed to measure the amount of neutralizing antibodies produced in humans following routine vaccination. It was also used to measure neutralizing antibodies in mice following experimental vaccination. Undiluted serum is mixed with equal amounts of mouse passage virus in various dilutions, the mixtures are heated at 37° C., and each is injected intracerebrally into 4 mice. The titer of virus plus normal serum is read as that dilution giving 50 per cent or more mortality in the injected mice. This titer, 10^{-5} or 10^{-6}, is compared with that of virus plus unknown sera.

In one series of tests, sera of persons treated with vaccines containing live virus were found to neutralize 100 to 1,000 lethal doses of virus over periods as long as 4 years. In another series, 23 nurses, physicians, and laboratory workers, receiving the full course of 14 doses of Semple vaccine, "G", have thus far been tested over a 15 month period (Figure I). Their sera, by the last day of treatment, showed antibodies neutralizing for the most part 1 to 10 lethal doses of virus. At 2 months, all those tested neutralized 10 to 100 or more doses, and from that time through 15 months all neutralized a full 100 lethal doses of virus. Finally, a group of 17 persons, receiving Semple vaccine, "N", from another laboratory, failed to neutralize the virus to any significant degree over an 8 month period (Figure I). Apparently, therefore, not all preparations of Semple vaccine are equally potent in stimulating neutralizing antibodies in humans.

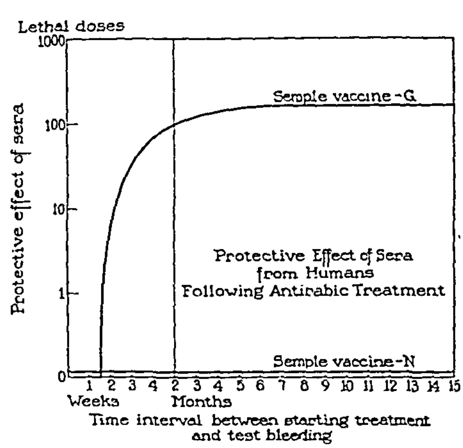

FIGURE I—Protective effect of sera from humans following antirabic treatment

Attention was next turned from humans to mice to determine whether commercial vaccines could produce not only neutralizing antibodies but actual resistance. Since some of these vaccines contained live virus, tests were also made of the effectiveness of virulent mouse passage laboratory virus. Live virus given subcutaneously in a single dose supposed to contain 1/10 the average minimum infecting dose produced rabies in an occasional mouse and in the remainder stimulated but little neutralizing antibody production and little resistance to a subsequent intracerebral test infection. A smaller vaccinating dose still brought down an occasional mouse with rabies and failed to immunize. Live virus given intraperitoneally, on the other hand, proved less infectious, and a single dose containing 1/10 to 1/100 of the average minimum infecting dose, although it produced rabies in the frequency of about 1 animal in 100, stimulated neutralizing bodies within 10 days in the remaining 99 per cent and rendered them actually resistant to 1,000 intracerebral lethal doses. This resistance has lasted 6 months and is active against all strains employed. Vaccination of mice with mouse passage, live virus, therefore, is dangerous and unsatisfactory if given subcutaneously; if given intraperitoneally in a single dose, it remains slightly dangerous but very effective.

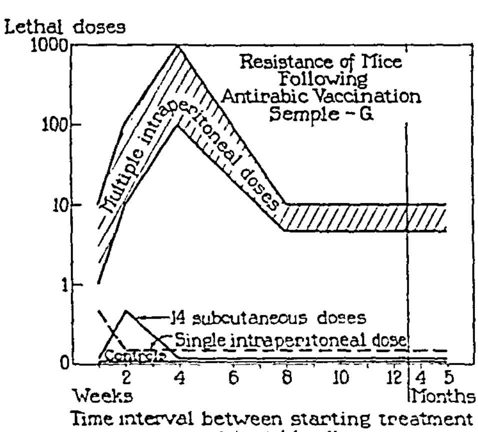

FIGURE II—Resistance of mice following antirabic vaccination, Semple " G "

Commercial vaccines said to contain live virus, when injected intracerebrally, brought mice down promptly with rabies, but when injected peripherally were relatively harmless. Given to mice as a vaccine according to directions, by the subcutaneous route, they did not immunize; by the intraperitoneal route, however, they produced both neutralizing antibodies and resistance in high titer. In this respect they resembled the single dose of virulent laboratory virus.

The standard Semple vaccines have been studied with special care. In the first place, Semple vaccine from laboratory " G " which in humans produced high titer neutralizing antibodies, when tested for the presence of live virus, invariably gave negative results. Repeated injections of many specimens directly into the brain, filtering or sedimentation of large particles of tissue in the vaccine, emulsifying them and injecting them intracerebrally and intraperitoneally in large doses have failed to produce rabies. If live virus was present at all in the " G " vaccines, it was there in minute, subinfective amounts. Secondly, Semple vaccine " G ", when properly employed, rendered the mice highly resistant to an inoculation of rabies virus directly into the brain (Figure II). But to achieve this resistance, vaccination was required not by the standard subcutaneous route but by way of the peritoneal cavity. Batches of 50 to 75 mice were vaccinated by different routes and with different numbers of doses, and tests made subsequently of their resistance to intracerebral injection of virus and their serum-neutralizing properties. The intraperitoneally vaccinated mice de-

veloped resistance within 7 days to 10 to 100 intracerebral doses of virus and also showed strong serum-neutralizing antibodies. Both antibody and resistance titers have continued at high levels during the 5 month period tested. Six intraperitoneal doses, 1 every other day, proved nearly as effective as 14 doses, 1 per day; 3, with 1 every other day, seemed ample for prophylaxis. A single intraperitoneal injection of vaccine did not render the mice resistant to the intracerebral test dose. The required amount of vaccine per dose proved considerably in excess of that employed for man per gm. of body weight. Finally, the effectiveness of "G" vaccine was found to deteriorate rapidly within 4 months after preparation.

Neutralizing antibodies were not invariably a direct index of the presence of resistance (Figure III). While vaccination of mice by the subcutaneous route failed to produce either antibodies or resistance, and *multiple dose* vaccination by the peritoneal route produced both, a *single dose* peritoneal vaccination produced antibodies but no resistance as tested. This question is being studied further.

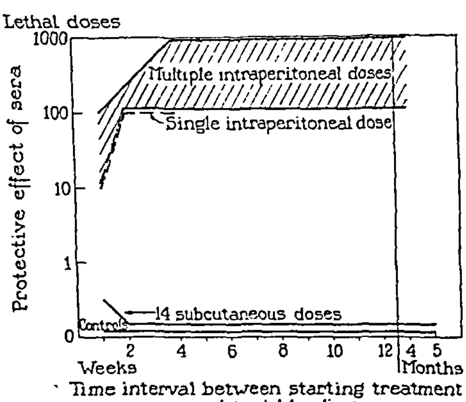

FIGURE III—Neutralizing antibodies in mice following antirabic vaccination, Semple "G"

From these experiments a test for evaluating the efficacy of antirabic vaccines in mice is being developed. The material is injected first directly into the brain and muscles of mice to detect live virus. Second, mice are vaccinated intraperitoneally with 6 doses, 1 every other day, each dose comprising ⅛ the stated volume diluted 10 times. These vaccinated mice are tested subsequently for their intracerebral resistance on the 10th and 21st days. The test, as now run, will doubtless be improved, but already it has classified the preparations into (A) those containing demonstrable live virus and protecting mice; (B) those containing no demonstrable live virus and protecting mice; and (C) those containing no demonstrable live virus and not protecting mice.

In conclusion, the diagnostic test, neutralizing antibody test, and resistance test provide methods for the quantitative study of rabies. Results thus far suggest, from the theoretical viewpoint, that neutralizing antibodies are not always a direct measure of resistance, and that vaccines containing no demonstrable living virus may produce resistance. Moreover, they show that the optimum method of securing prompt and effective immunity to rabies in the mouse is by the intraperitoneal injection of relatively large amounts of vaccine, 6 doses, 1 every other day. The work suggests from a practical viewpoint that rabies vaccines should be employed which have a high rating according to the mouse test.

Bacteriological Examination of Glassware or China for Sanitary Quality*

C. R. FELLERS, PH.D., F.A.P.H.A.,
A. S. LEVINE AND E. W. HARVEY

Massachusetts State College, Amherst, Mass.

THE time has come when something must be done about the insanitary conditions prevailing in connection with the dispensing of beverages. Both the public and the public health officer agree on this. Although the problem has been met in some places by the use of single service paper cups, it is common knowledge that glasses are only superficially washed or disinfected between patrons. Our personal observations are that in many places dispensing beer, the glasses are not washed at all. This is probably true to a lesser extent in other beverage dispensing establishments. Sporadic efforts have been made to remedy this situation in some cities. At best, such efforts have been considered only partially successful even by their sponsors. As Calver [1] has pointed out, there is a real opportunity to better control of respiratory diseases by means of improved sanitation of glasses and other eating utensils.

However, before we can expect the health officer or his inspectors to improve conditions very much, he must be provided with certain information. First, he must have a reasonably reliable method whereby he can determine whether glasses and dishes have been improperly handled; second, he must be able to offer definite constructive suggestions as to effective washing equipment and methods. We believe that the lack of positive information on these points has delayed the carrying out of a much needed program of education and compulsion in regard to the unclean utensil situation.

METHODS IN USE

A good list of technics for the bacteriological examination of glasses has been compiled by Calver.[2] These include various modifications of the swab method, rinsing, direct plating of utensils, direct microscopic examination after staining, and several others. The agar disc method, used by Olson and Hammer [3] to study churn contamination, was considered by us to merit some study as to its possible use in public health work. The agar medium is allowed to solidify. The agar disc is then picked up with a sterile spatula,

* Read at a Joint Session of the Laboratory, Food and Nutrition, and Public Health Engineering Sections of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 23, 1936.
Contribution No. 258, Massachusetts Agricultural Experiment Station.

placed in a sterile Petri dish and allowed to incubate. The colonies developing on a measured area are counted and the results expressed as number per sq. cm.

COMPARISON OF VARIOUS BACTERIOLOGICAL TECHNICS

In all, 18 different methods of sampling glasses and dishes were compared for utility, accuracy, speed, and simplicity.

A method to be of use to the busy health officer or his laboratory must be relatively simple. We realize that no method will give much information as to pathogens. Of the many organisms transmitted by the mouth secretions, only the diphtheria bacillus and the pathogenic cocci can be recovered with any degree of success. We must then turn to total counts to guide us in making a decision as to the sanitary quality of glassware and its likelihood of transmitting disease.

The agar disc method was too difficult to use, resulted in too many failures, and could be applied only to small areas of the glass. However, the recovery of bacteria artificially inoculated on glasses was approximately 50 per cent. The microörganisms used were *Serratia marcescens* and *Escherichia coli*.

The making of rim impressions of glasses and other containers on agar plates was tried many times. Both firm and soft agars were used. This method possesses the disadvantage of contacting only limited portions of the container. It is subject to contaminations, is not readily carried out in restaurants or drinking places, and results cannot be easily duplicated. Furthermore, colonies tend to be confluent, and counting is difficult.

Direct plating of pieces from broken glasses and cutouts from paper cups were investigated. This method is decidedly unsatisfactory from many points of view. Direct microscopic examination of broken glass rims, stained with various stains in an effort to make the bacteria visible, was almost a total failure. In the case of paper cups, the method failed to give good duplicate results and bacteria often failed to grow from the surfaces of the waxed paper, even though they had been artificially inoculated.

The many variations of the swab method will not be enumerated here. We tried swabs of different sizes with applicators of different lengths in test tubes containing broth, saline or distilled water. Different methods of swabbing, and a number of media were also tried out. In general, all swab methods were very practical, rapid, and simple. The recovery of bacteria was always over 40 per cent and often 75 per cent with *Serratia marcescens, Escherichia coli,* and *Streptococcus hemolyticus*. In mixed cultures used as inoculating suspensions, the percentage recovery was always less than when pure cultures were used. The many data obtained were used in the formulation of the standard method here proposed. They are too numerous for reproduction in this short paper. While the method in itself is not new and various parts have been previously described, we feel that a definite procedure if adopted by health laboratories for glassware examination will yield comparable results and will serve to give an excellent idea as to the sanitary condition of glassware.

PROPOSED STANDARD METHOD

SAMPLING

The method consists in preparing medium sized cotton swabs on wooden applicators immersed in approximately 3 c.c. of saline (0.8 per cent NaCl) in ordinary 25 c.c. culture tubes. The tubes are cotton stoppered with the

applicator sticks protruding slightly above the plugs. Sterilization is accomplished by autoclaving at 10 lb. steam pressure for 20 minutes. To avoid evaporation, storage should be at low temperatures.

Boxes or packets of these tubes are taken by the inspector who secures his samples as follows:

> Remove the plug; lift the applicator above the surface of the liquid; press against the side of the tube and twist so as to squeeze out as much excess saline from the swab as possible. Remove the applicator and thoroughly swab the inside and outside lips and rims of glasses. Replace the applicator in the culture tube and insert the cotton plug. A number of glasses should be swabbed in each establishment in order to obtain a fair average. Tubes should be labeled and returned to the laboratory for plating within a few hours, preferably 2 hours.

PLATING OF THE SAMPLES

Upon arrival at the laboratory the tubes are agitated by holding firmly in the hand and striking 25 times. Remove the plug, squeeze the cotton swab as before to remove excess liquid, and discard. The liquid contents of the tube are poured into a Petri dish. There is actually only a very small amount of liquid retained by the swab. At this point, the swab may be used to inoculate Loeffler's blood serum slants in an effort to isolate pathogens.

Next 7 c.c. of nutrient agar (2 per cent agar) is poured in the Petri dish and mixed thoroughly. Incubation is at 37° C. for 48 hours. Counts are recorded for individual glasses and not as averages.

With slight modifications the above

TABLE I

TEST OF PROPOSED METHOD USED IN SOME EATING PLACES

Establishment		*Bacteria per Glass Individual Counts*	*Average*	*Method of* *Cleaning*	*Rinsing*	*Drying*
Soda Fountain	1	3, 0, 2, 1, 9, 8, 1, 3	3	soap and hot water	hot water	metal racks
" "	2	3,900; 3,700; 670; 3; 20,700; 280	4,880	soap and tepid water	sozzle	shelf under counter
" "	3	2; 3; 580; 5; 120; 13,300; 9,300	4,720	dirty dish water	sozzle	metal racks
Restaurant	1	5,600; 360; 460; 3,300; 3,300; 2,100	2,520	dirty dish water	tepid water	dirty towel
"	2	150; 10; 45; 20; 23; 25	48	soap and hot water	hot water	clean towel and tray
"	3	134; 11; 400; 500	260	soap and hot water	hot water	dish towel
"	4	50: 15; 10; 8; 16	20	soap and hot water	hot water	dish towel
"	5	10; 12; 45; 9; 3; 4	14	steam washing machine	unnecessary	dish towel
Bar	1	2,800; 11,000; 50; 40; 160; 1,900; 20	2,280	warm water no soap	warm water	none
"	2	too numerous to count approximately 350,000	350,000	merely rinsed	cold water	none

method is easily adapted to the examination of dishes and silverware.

While occasional plates may be overgrown or colonies too numerous to count, the writers feel that plating the whole sample is better than making routine dilutions. At least, the results give an excellent idea as to the sanitary quality of the glassware examined. The method is also useful in the study of bacteriological effectiveness of mechanical dish washers and cleaning and sterilizing compounds.

Table I summarizes the results of a practical test of the proposed method used in some public eating and drinking establishments. A good correlation is shown between the care in cleansing and the number of viable organisms left on the glassware. These results should not necessarily be viewed with alarm, but they can be taken as good indications of the general sanitary conditions of the individual establishments. High counts should warrant more critical routine inspection by the health departments.

SUMMARY

A comparison of various methods for the bacteriological determination of sanitary quality of drinking glasses and eating utensils showed the swab method to be most satisfactory. From 40 to 80 per cent of the organisms present are recovered by this technic.

Specific directions are given for preparing sampling tubes, taking and handling samples, and recording results. These can be carried out at small expense in any health laboratory.

Practical tests of the method show it to be rapid, simple, and reliable. Health laboratories can use the method in a routine way to check cleansing and sterilization of utensils in food and beverage *dispensing establishments.*

Novel Purification Design

. . . The principal novel features of Burnt Mills, Md., water purification works pertain to the treatment unit assembly, containing a pipe vault, 4 filters, each of 1¼ m.g.d. nominal rating, a filter control house, a coagulating basin having a 55 minute detention period, and a 275,000 gal. filtered water reservoir. These are built of steel, cylindrical in form, and arranged concentrically. The flat continuous bottom of the structure rests on a thin concrete base lightly reinforced and the outside frame of the reservoir is surrounded by a loose rock collar to a height of 4′, beyond which there is earth fill. All seams are welded with the exception of the roof of the filtered water reservoir which has a thickness of 3/16″, all plating is 5/16″ thick. No deterioration of the steel work in the plant has been found at the end of approximately 1 year's operation. At the present time a second filter plant of 5 m.g.d. capacity, is under construction.—*Annual Report of the Bureau of Sanitary Engineering of the Maryland State Board of Health—Year 1935.*

International Standardization of Biological Products by the League of Nations*

GEORGE W. McCOY, M.D

Medical Director, U. S. Public Health Service, and Director, The National Institute of Health, Washington, D. C.; Consultative Member of the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations

WHEN we begin to think in terms of standardization from the international point of view, it is natural that we should consider what has been accomplished in fields other than those that are of special interest to us. Certainly not much standardization of language exists; there are at least two systems of weights and measures in common use; and we begin to think that perhaps time alone is universally standardized in the civilized world until we recall that the 24 hour day is in common use in much of Europe, and that we in some parts of the United States have been introducing a little elasticity by having daylight saving time during the summer months.

The question naturally arises as to how the United States came to participate in the League of Nations Conferences on Standardization while not a member of the League. The answer is that our State Department was equal to the task of deciding promptly when the matter was presented to it, and it was prescribed that the American representative should serve in a consultative, not in an advisory capacity. There really is a difference, if you think long enough about it. In practice it works out that he functions in the same manner as other members of the commission but does not vote.

The Standards Commission is a creature of the Health Organization of the League of Nations and accordingly its actions are subject to the approval or disapproval of that body.

There are two international organizations functioning in the field we are considering—the Permanent Standards Commission of the League, which has had about half a dozen meetings and has adopted the standards mentioned below, and the Inter-Governmental Conference on Biological Standardization to which were invited representatives of practically all of the countries of the world. This body has had but one meeting and, in general, adopted, without appreciable modification, the standards established by the Permanent Standards Commission.

The commission naturally takes into account any work that has been done

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New Orleans, La., October 21, 1936.

prior to its own consideration of any subject. Thus, for example, Professor Weinberg, of the Pasteur Institute, who has long been interested in the gas gangrene group of organisms and has done much work with these anaerobes was in a position to furnish a serum on which a standard for Vibrion septique antitoxin could be based. This serum was reduced to a condition to assure permanence, and a test dose was then determined. A previously ascertained unit of test toxin and an antitoxin of unknown potency were distributed for comparative testing in Copenhagen, Paris, Washington, and a number of other centers, 7 in all. The results at the 7 testing institutions were so close that it was decided to adopt the unit for international use.

In general, the commission defines standards and prescribes units, usually in terms of fractions of a milligram of the dry standard, but it does not undertake to lay down methods of testing, this being left to the individual choice of the various national laboratories. Standard preparations are distributed from the State Serum Center at Copenhagen for members of the serum-bacterial group, and from the National Institute of Medical Research, London, for hormones, vitamins, and other preparations in which the question of immunity does not arise.

It has been the policy of the commission to standardize preparations used prophylactically or therapeutically without reference to the degree of usefulness, the only policy that, in my judgment, could be readily justified.

The commission has refrained from taking action with respect to preparations where the standardization seems hopeless, for example, in the case of antimeningococcus serum. This preparation is often the subject of discussion by the commission and it always ends in the same way, namely, that we are still without sufficient information for effective standardization.

In addition to preparations of the group in which considerations of immunity arise and in which we are especially interested, the committee has undertaken through experts the standardization of certain drugs, for example, digitalis; certain hormones, for example, insulin; and nearly all of the group of vitamins.

Standards originating in America have fared very well with the international commission. It has adopted our units for antipneumococcus serum and for perfringens antitoxin. The latter is the most important member of the gas gangrene group.

The first unit to be adopted by the commission was that for diphtheria antitoxin. Here there was no difficulty in agreeing on the Ehrlich unit as it was used universally throughout the world although distributed from two centers, Frankfort am Main and Washington, D. C.

The international standard unit for tetanus antitoxin probably has provoked more discussion and has been the subject of more difference of opinion among members of the commission than any other five products, and that is putting it mildly. The competition for favor lay between the old German unit and the American unit, the former having the merit of priority, the latter of convenience in "size." Both were extensively used, probably about equally if we consider the whole world. The German unit was about 66 times the size of the American unit and it was generally recognized that this was inconveniently large. Therefore the German authorities adopted a new unit, approximately half the strength of the American unit. This new German unit was later adopted by the League Commission over the protest of the American representative. The attitude of

the American control authorities was, and has been, that they would be willing to consider any new unit that offered advantages over their own. As the situation stands, the two units are widely used and, indeed, some official control authorities require the label to show the number of units according to the two standards. The American control authorities require the use of the American standard and permit the use of the international unit. The matter is not without practical significance since 1,500 units of the international potency, the usual prophylactic dose of tetanus antitoxin, contains approximately the equivalent of 750 units according to the American standard. I say approximately because it has been shown that the new unit is not precisely one-half the American, but the difference is not of great importance.

Standards for scarlet fever preparations have not been adopted by the commission chiefly because of the control over these preparations by the organization holding the patents covering them. Personally, the writer doubts the wisdom of this policy of nonrecognition since the United States control authorities have found it practicable to standardize and control scarlet fever toxin and antitoxin in a manner which appears to be satisfactory to all concerned.

Antipneumococcus serum is the only antibacterial serum that is in contrast with antitoxic serum, that has been standardized.

I think all of you will appreciate the reluctance of control authorities to adopt units for antibacterial preparations. We are so accustomed to thinking in terms of toxin in serum neutralization tests that it goes against the grain to contemplate a standard unit based on a living culture.

Thanks to the work of Dr. Lloyd D. Felton, to whom the modern production and application of antipneumococcus serum is so largely due, and to the perseverance in attempts at standardization by certain commercial manufacturers of antipneumococcus serum, the difficulties were to a large degree overcome. After carrying on tests in various laboratories, the commission adopted the standards for types I and II. Dr. Felton's F-146 was taken as a basis for the standardization, and units were defined in the usual manner.

Aside from the tetanus unit, there has been but one immunological preparation on which the American delegate could not see eye to eye with his European colleagues. This was diphtheria toxin for the Schick test. The committee adopted a standard which took into account the neutralizing power of the toxin as well as the toxicity, whereas the American requirements cover only the test for toxicity which we have found quite satisfactory.

While the members of the arsphenamine group of preparations do not fall into the serum-bacterial group they should, on account of their interest to public health authorities, be mentioned here chiefly because the United States authorities employ methods of control different from those adopted by the League of Nations Commission. The first point of essential difference lies in the fact that the United States control authorities have not adopted a standard control preparation with which new commercial batches may be compared in toxicity tests. It was felt by the American authorities that assays were quite satisfactory when based simply on establishment of the toxicity of the preparation without the use of an official control standard, a method which has given satisfactory results over a period of many years.

The second essential point of difference lies in our unwillingness to adopt an animal test for therapeutic

Standard	*When Adopted*	*Int. Unit in Milligrams*

Staphylococcus antitoxin	1934	0.5000
Diph. antitoxin for the flocculation test	1935	
Old tuberculin	1931	

activity. Our disinclination here springs from the conviction that the trypanocidal activity test does not furnish useful information in terms of curative action as applied to clinical conditions. A spirocheticidal activity test, which is the alternative permitted by the commission, seems impracticable of application on account of the length of time required to carry it out and the inherent uncertainties and difficulties of the test. Perhaps the satisfaction of control authorities in the United States with respect to our methods in this field arises from the fact that in the nearly 20 years of their use, there has not come to light any evidence of excess toxicity of any preparation that could have been detected by any other method of testing in use anywhere. Furthermore, there is no evidence of want of therapeutic efficacy of any product in the American market, whether produced here or abroad.

The above tabulation taken from the report of the Inter-Governmental Conference on Biological Standardization at Geneva, 1935, shows the progress that has been accomplished by the commission in the serum-bacterial group. All of these are distributed by the State Serum Institute at Copenhagen.

ACKNOWLEDGMENT

The Permanent Standards Commission has had the unselfish aid of two special experts, to whom acknowledgment is due, Dr. Percival Hartley, of the National Institute for Medical Research, London, and Professor Claus Jensen, of the State Serum Institute, Copenhagen.

We cannot close this brief account of the work of the Permanent Standards Commission without saying that whatever measure of success has attended the work of the commission, and I think it has been large, has been due almost entirely to the ability and to the influence of the gentleman who has been chairman throughout the period of the existence of the commission, Professor Th. Madsen, a man who, had his talents not been devoted to science, would have taken high rank as a diplomat—indeed, his diplomatic talents have been called into use in connection with the work of the Standards Commission about as much as his scientific attainments.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

SAVE THE SURGEON GENERAL'S LIBRARY

"THE outstanding contribution which our country and its government have made to medical knowledge "— In these words of Dr. William H. Welch, the Medical Library Association in a resolution adopted at its 38th annual meeting, aptly characterizes the U. S. Army Medical Library and the *Index-catalogue* which it issues. The Medical Library Association in this resolution given herewith urges the Congress of the United States to appropriate adequate funds for the maintenance and growth of the collection of books and the preparation of the *Index-catalogue,* which Major Edgar E. Hume, present librarian of the Surgeon General's office, calls " The most comprehensive piece of bibliography ever attempted in any field of knowledge."

In 1840 the Army Medical Library was started for the purpose of stimulating interest in medicine among army surgeons. In 1868 Dr. John S. Billings became librarian and, with a vision seldom found, started to build up this monumental collection and the accompanying catalogue. He labored for over 25 years in this field and succeeded in that time in making this library of indispensable service to the medical profession not only of the United States but of the entire world. Dr. Billings's conception of the library was that it should disseminate knowledge of medicine as well as catalogue it and his catalogues and bibliographies have become the means for such dissemination. It is not too much to say that every physician and public health worker in the United States has profited and is profiting by the vast fund of knowledge made available to teachers and research workers as well as to the humblest practising doctor in the country through the bibliographies published from time to time under the heading *Index-catalogue.*

Since Congress has adopted a somewhat niggardly attitude toward the library, it behooves all of those interested in better health for the individual and the community to support the resolution of the Medical Library Association. The conception of the library, created by Dr. Billings and forwarded by Dr. Fielding H. Garrison and Dr. Robert Fletcher, has been carried on by successive

librarians in recent years. Attempts have been made to combine this library with the Library of Congress but, in the opinion of those who know the Surgeon General's Library best, such a combination would be disastrous to best bibliographical work in the field of medicine.

The publication of the *Index-catalogue* is naturally dependent upon the availability of books and periodicals in all languages that present material suitable for listing in the *Catalogue*. The publication of such a work is very expensive. One thousand copies of each volume are printed and cost between $18,000 and $19,000 merely for the printing. The work of preparation increases the cost to more than $30,000 a volume.

Like other libraries, the Army Medical Library has had difficulty in maintaining its shelves and personnel during the depression. Appropriations for books have been cut from $20,000 annually to less than $15,000 and this, coupled with the fact that the purchasing power of the American dollar in European countries has fallen considerably, makes the appropriation even smaller. Funds are needed for books to fill the gaps left vacant during the last 5 years and to buy new publications and periodicals recently issued. Cataloguers and other personnel are expensive, and money for this purpose is needed. The total amount, however, is an insignificant sum compared with the hundreds of millions and billions being appropriated for other army and navy purposes and for a great variety of other projects.

Readers of the *American Journal of Public Health* are urged, therefore, to present the important matter of maintaining the Medical Library of the Surgeon General of the U. S. Army to their senators and congressmen before the next session of Congress. Most of these men have no conception of the real significance and value of this great collection of books and of the *Index-catalogue*. It ought not to be difficult for medical and lay public health workers to make congressmen feel that an adequate appropriation for the Surgeon General's Medical Library is essential to the health and well-being of every citizen in the country. Let us mass public opinion to support this, the greatest medical library in the world.

RESOLUTION RECOMMENDING THE APPROPRIATION OF ADEQUATE FUNDS FOR THE MAINTENANCE AND GROWTH OF THE ARMY MEDICAL LIBRARY'S BOOK COLLECTION AND INDEX-CATALOGUE.

The Medical Library Association, comprising two hundred of the medical libraries of the United States and Canada, assembled in its thirty-eighth annual session in St. Paul, June 22, 1936, notes with pleasure and pride the appearance of volume one of the Fourth Series of the *Index-catalogue* of the Library of the Surgeon-General's Office, United States Army (Army Medical Library). The Association records with satisfaction the abbreviations and changes in composition in this new volume effecting a saving of twenty per cent in space with accompanying reduction in cost.

After a delay of three years during which no volumes of this *Catalogue* were printed, the appearance of this first volume of the Fourth Series gives renewed assurance of the continuation of this publication, which, together with the Army Medical Library, is considered the outstanding contribution which our country and its Government have made to medical knowledge, and

WHEREAS, The value and usefulness of the *Index-catalogue* is dependent upon the completeness of the files of medical publications contained in the Library of the Surgeon-General's Office—a public, national, medical library, the greatest in the world, serving in its present form of administration with satisfaction the medical profession and the medical libraries of our country, and

WHEREAS, In recent years the annual appropriation of the Congress has been wholly inadequate to provide sufficient funds to acquire the current medical books and periodicals issued throughout the world, so that they might be available for use throughout the country and for inclusion in the *Index-catalogue,* therefore be it

RESOLVED, That the Medical Library Association urges the Congress to appropriate annually to the Library of the Surgeon-General's Office an adequate sum for current medical books and periodicals and for the purchase of back publications lost during those recent years when the amount granted was grossly inadequate, thus depreciating the completeness and usefulness of the Library's collection; and an additional sufficient sum annually, for as many years as may be required, in order to make for the greatest possible completeness of the collection and its *Catalogue;* and be it further

RESOLVED, That a sum be appropriated annually to defray the cost of printing regularly each year not less than one volume of the *Index-catalogue,* and be it further

RESOLVED, That a copy of these resolutions be spread upon the minutes of the annual meeting of this Association and sent to the President of the United States, the presiding officer of both houses of Congress, the Secretary of War, the Surgeon-General of the Army, and to the national, state, and other medical periodicals with a request for publication, and to the members of this Association, urging the organization of which they are a part and all other medical associations and institutions to adopt similar resolutions to be sent to their local members of Congress requesting their support of these measures.

Preprinted from the *Bulletin of the Medical Library Association,* Vol. 25, No. 1, p. 12, September, 1936. Minutes of the Thirty-Eighth Annual Meeting, Session of June 22, 1936.

DR. CHARLES PORTER

PUBLIC HEALTH, Volume 50, No. 1, October, 1936, appears in a new dress and under a new editorship, Dr. Charles Porter, who has served as Honorary Editor since 1925, having retired. The new editor pays a well deserved tribute to him, pointing out that he had a real gift for journalism in the best sense of the word, and succeeded in endowing the pages of *Public Health* with character and dignity. He calls him the last, for the time being, of a line of distinguished editors, including such men as Sir Arthur Newsholme, Sir Shirley Murphy, and R. A. Lyster. Dr. Porter's editorship was interrupted for one year by his election as President of the Society of Medical Officers of Health of England.

It may be said with a high degree of certainty that readers not directly concerned with affairs of the Medical Officers of Health or with health administration in England, always turned first to the section headed "*Ut Ita Dicam*" (Being Comments, apropos and otherwise, on Sundry Matters). Here we had a running comment on practically every matter of interest in public health in England which had taken place during the preceding month. The writing was excellent and touched off with the wit that was characteristic of Dr. Porter. It is no disparagement to the new editor to say that this will be missed.

The arrangement of the Journal has been changed and a new cover adopted. It is interesting and covers affairs in England quite well; but if we may judge from the first issue, it will be devoted more strictly to summarizing the majority of papers read at meetings and to official affairs. It is planned, however, to ask for special articles reviewing new legislation and recent advances in the particular aspects of preventive medicine.

Our readers will remember the excellent letters in our *Journal* which came from Dr. Porter's pen. A year ago he found it necessary to discontinue these and they have been missed. For Dr. Porter we wish every good thing in life and assure him that he will be missed.

SOUTHERN BRANCH OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE Fifth Annual Meeting of our Southern Branch, held in Baltimore, Md., November 17–18, was in every way a great success. The attendance was by odds the largest at any meeting so far, with some 360 registrations. The quality of the scientific papers was very high. Speakers were attracted from various parts of the country, in addition to those who hold membership in the Southern Branch.

The arrangement of the program was made in conjunction with the officers of the Southern Medical Association, so that the sessions of the Public Health Section of the Southern Medical Association fitted in with those of our Southern Branch, making as it were one continuous meeting on public health, which could be attended by all interested in such subjects, since there was no duplication in hours and practically none in subjects.

Among the special features may be mentioned the Presidential Address by Dr. I. C. Riggin, State Health Commissioner of Virginia. This was a summary of the situation regarding poliomyelitis from the beginning of the 1935 epidemic up to the present time. It was followed by a description of the epidemic in Alabama in 1936, by Dr. Baker, State Health Officer, after which Dr. Charles Armstrong, of the Public Health Service, gave the results of his studies on the use of picric acid spray as a preventive of the disease and his results in Alabama. This paper will be given in full in our pages in an early issue. We can only say here that it seems to offer the best hope we now have for the prevention of this dreaded disease. It was listened to with marked attention, and further studies will be carried out.

All of the meetings were well attended, the large room assigned being packed at times until there was only standing room. Needless to say, members of the Southern Medical Association attended our sessions in considerable numbers and, as already said, the combination of the two bodies had all the appearance of a continuous meeting on public health, in which both societies took apparently an equal interest. It goes without saying that many members of the Southern Medical Association are members of the American Public Health Association and also of our Southern Branch.

We cannot speak too highly of the arrangement which has been in effect for several years, that is, several smaller societies holding their meetings in conjunction with the Southern Medical Association. In addition to our Southern Branch, other societies concerned in public health also had their meetings. The National Malaria Committee, in which we are all interested, and the American Society of Tropical Medicine had their sessions in Baltimore, both with valuable papers of interest to all health officers and health workers. Indeed there was intellectual food for all, which it will take many months to digest, and all present are looking forward eagerly to the publication of the papers as matters of permanent record.

The weather was all that could be desired, sunshiny and cool. The people of Baltimore were most gracious in their hospitality. The new Fifth Regiment Armory, in which the meetings took place, was spacious and was most admirably arranged, not only for the scientific sessions but for the scientific and commercial exhibits, of which there were a very large number. It is needless to speak of

the social side of this meeting. The fact that it was in Baltimore carries assurance that it was delightful in every way, being in this beautiful old city with many points of historical interest dating back to the beginning of our country. On every side there were streets, monuments, and buildings carrying names familiar to everyone who has read the history of the foundation of our country. To the people of the city of Baltimore, we owe gratitude.

PUERPERAL FEVER

THE House of Lords of England on July 14, 1936, handed down a judgment on an interesting case in which there is a lesson for us in America.[1]

In January, 1933, Mrs. M. arranged for a private ward for her confinement in the Maternity Home of 16 beds maintained by the Lindsey County Council. She went to the Home on July 12 and, there being no private ward available, entered the public ward. On the 13th she was confined. On July 14, four other patients developed puerperal fever, and on July 17, Mrs. M. became acutely ill with the same infection, but finally recovered. On this date, at the instance of the medical superintendent, the home was closed.

In November, 1933, Mrs. M. brought suit against the County Council for breach of contract; for negligence in not closing the ward on the occurrence of a case of puerperal fever on July 4; and for negligence in failing to inform her, her husband, or her medical adviser that there had been such a case. She won, and judgment was entered for her in the sum of £750, with costs. The Court of Appeal, with one dissentient, affirmed the finding on February 8, 1935. On July 14, 1936, the House of Lords dismissed the appeal of the County Council against this decision. The Lord Chancellor accepted that the jury was justified in holding that without taking swabs there was a grave risk that a carrier might be present, and that until that risk had been eliminated, it was dangerous to admit a new patient to the Home. He held also that if new patients were admitted before the presence or absence of a carrier on the staff had been determined, the doctor in attendance should be informed of the facts and allowed to decide whether his patient should enter the Home, or to decide on what precautions should be taken if the patient were admitted.

It seems then that it is a neglect of duty on the part of a maternity home on the occurrence of a case of puerperal fever (1) to admit any patient to the home without first taking swabs from the staff, and (2) to fail to inform the patient, her husband, or her doctor of the occurrence of a previous case in the home.

Comments on the public health aspects of this case in the *British Medical Journal*[2] say it is a common practice to comply with the first requirement, and hold that it is apparently advisable to do so in all cases, just as there are now examinations for the presence of the Klebs-Loeffler bacillus, X-ray pictures of injured limbs, etc., in order to protect the attending practitioner rather than in the strict interest of the patient. The second requirement offers greater difficulties, as there is no indication of the length of time over which the giving of this notice should extend, or as to whether the necessity of making such a declaration is voided by swabbing, excluding any members of the staff, disinfecting the premises, closing the ward or the entire home, etc. It is held that it is not in the

interests of the patient to submit to her a complete history of the infections that have occurred in the home. It is suggested that it might be well to inform the attending physician and let him make the decision, but that this might lead to his appearance as a defendant.

The history of the case is most interesting and instructive. Certainly some things in England are better managed than in America, though the time taken for the decision by the House of Lords reminds us of the delays in our American courts.

PRESENTATION OF WALTER REED MEDALS

THE meeting of the American Society of Tropical Medicine, held in Baltimore, Md., November 18–20, was made notable by the presentation of two medals. After telling the story of the conquest of yellow fever, which was brought about so largely by the work of Major Walter Reed of the United States Army, a gold medal was presented by proxy to his widow. It was received by Major General Walter L. Reed, Inspector General of the Army, the son of the man in whose honor this series of medals has been named.

We need hardly remind the readers of this *Journal* that Major Walter Reed died before our government had given any proper recognition to the work of which he was the head, either to himself, the members of his committee, or to the volunteers who risked their lives for the benefit of humanity.

The other Walter Reed Medal was presented to the Rockefeller Foundation in recognition of the work which has been carried on by them in practically every part of the world for the eradication of yellow fever, which is now so well advanced.

PUBLIC HEALTH EDUCATION*

Fifteenth Anniversary Overlooked—Quite without remembrance by even those most concerned, the 15th anniversary of the Public Health Education Section came due in October.

In the spring of 1921 a letter was addressed to A. W. Hedrich, then executive of the A.P.H.A. with headquarters in Boston. The letter suggested that health education be given space on the program of the Annual Meeting to be held in New York the following October.

Mr. Hedrich replied to this effect. "Why not? Go to it." And so two sessions were planned, and the attendance was so large and representative that a provisional section was organized with Dr. Lee K. Frankel as the chairman. After a year or two the Section was made permanent, and here we are, having passed the 15th anniversary of those first meetings in a ballroom of the Hotel Astor in New York City.

Possibly next year some of the committees authorized at New Orleans may assess the past, and attempt a glimpse into the future.

We Are Discussed—At New Orleans the "Use of the Department in the *Journal* Devoted to Health Education" was the subject for a luncheon session.

A report was presented on the extent and nature of the material in this department of the *Journal*, in earlier years called "Education and Publicity," and now known as "Public Health Education."

Mr. Routzahn raised questions as to the content of the department, and it was agreed that the Section should have a committee to study the matter, and to give some coöperation.

In One Hundred and Fifty-six Issues—This department started in the issue for July, 1923. Including Oct., 1936, it has appeared in 156 issues, with none in two issues of 1924, and in one each of 1929 and 1935. Dr. H. E. Kleinschmidt edited one issue. The size range runs from 1½ pages to 10 pages in an issue, with an average of 8 pages in the 1935 and 1936 issues, and a total of 779 pages.

What We Try to Talk About—In this department we try to offer practical help to workers in varying types of health agencies. We try to suggest and illustrate new materials, new methods, new audiences. A wholesome questioning is encouraged as to what we have always done and the ways of doing things. We try to have many people represented in what is mentioned and what is quoted. What someone has said or done is usually the text for any comment or suggestion. This includes the repetition of commonplaces and abc's. But there are always new crops of readers coming along.

To the thousands of health agencies represented by readers of this department we have tried to offer a fairly complete list of new helps, new materials for health education and publicity. But we are limited to the information which reaches us.

And many good ideas and useful

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

materials are hidden under the bushel of the state or city of their origin.

Our Little Crusades—We have talked about indexes and tables of contents, and awarded honorable mention when included in annual reports. We have urged that editors be told when we like what they publish about health, and that radio stations learn what we think of their handling of health topics. We have tried to explain what " discussion " really is in a convention program, and how to bring it about. We have asked for criticism of what has been published. We have pleaded for comebacks from our readers.

What of the Future?—None of the questions raised at the New Orleans luncheon were answered. What don't you like? or what do you believe is least useful? *If* you *could* get what you wanted, what would you like in this department? If they could get what they wanted or what they needed, what would that be? How can the editor secure what national agencies now fail to supply? How can he secure what is received from state and local sources?

How can we organize group editorship to take over the coöperative educational opportunity offered by this department?

Health Education at New Orleans—That none may overlook the part of health education in the New Orleans meeting of the American Public Health Association, the record is briefly reviewed.

In a special session, " Advances in Public Health," Dr. William P. Shepard presented " Recent Progress in Health Education Methods."

Health Officers Section had " The Need for and Value of an Intensive Program of Health Education in State Health Departments," by Dr. Felix J. Underwood.

American Association of School Physicians devoted part of a session to " Health Education," by Fannie B. Shaw.

The Public Health Education Section had three luncheons, one dinner, two half-day sessions, and one joint session with Child Hygiene Section.

The technical exhibits contained a measure of health education value; there were extensive scientific exhibits, and Health Education and Publicity Headquarters.

Motion pictures and lantern slides were shown as features of several programs of the convention, and pictures were scheduled at the close of Public Health Education Section meetings.

A broadcast of the American Medical Association was received in Exposition Hall, and numerous broadcasts were given over local stations during the week.

Exhibits, Scientific or Otherwise—The Scientific Exhibits have become an important feature of the Annual Meeting . . . even though not all of them are scientific . . . and some are not exhibits . . . for unhappily the term " exhibit " calls for a reasonable measure of graphic presentation . . . which is absent from a mere aggregate of words and numerals . . . but the graphic is winning its way . . . even though many of the nearby technical exhibits are merely booths filled with many things.

The editor would like to comment on some of the exhibits, but the space had better be given to other delegates who were at New Orleans. The first speaker is—your name, please!

Health Education and Publicity Headquarters—Wall material came from various sources for the display at New Orleans. Classified portfolios were supplied by Social Work Publicity Council, 130 E. 22d St., New York, N.

Y., with other portfolios from health agencies and commercial groups.

The collection was classified as follows:

Annual reports; campaigns; house organs; bulletins; meetings; newspapers; radio; dramatic material; exhibits and expositions; money raising, letters of appeal; magazine articles; pictorial publicity, photographs, maps, diagrams, visualization, motion pictures, strip film, posters; printed matter, mimeograph, offset; health education, school, adult; health topics; periodicals; city and county; state; national; commercial; unclassified (including syphilis in press and radio).

These portfolios may be consulted at any time at the Council's headquarters in New York City.

Movies at the Annual Meeting—There ought to be a chance for health workers to see new motion pictures and other projection material. So far no satisfactory plan has been worked out. Suggestions would be welcomed by the Program Committee.

The following pictures were available at New Orleans:

"Sylvatic Plague" and "Psittacosis," by Dr. K. F. Meyer, University of California, San Francisco, Calif.

"Malaria," by Winthrop Chemical Company, New York, N. Y.

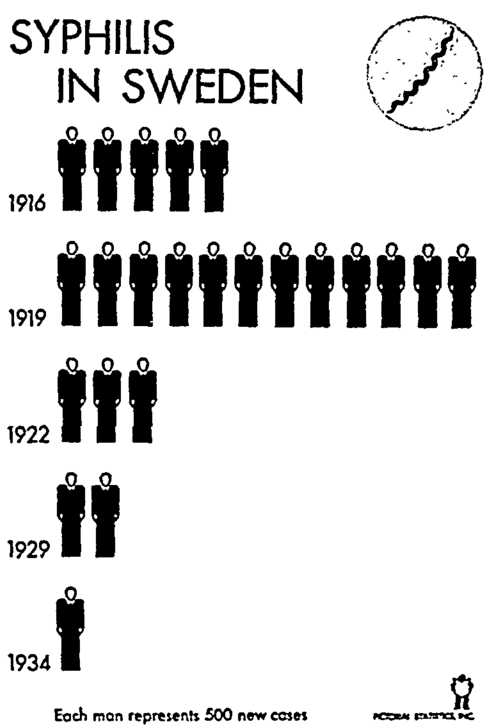
"Behind the Shadows," by National Tuberculosis Association, New York, N. Y.

"For All Our Sakes," a talking slide film by American Social Hygiene Association, New York, N. Y.

More Than Six Million Readers—And the end is not yet for the *Survey Graphic* article on syphilis, "The Next Great Plague to Go," by Dr. Thomas Parran. The article appeared in *Survey Graphic,* July, 1936. In abbreviated form it appeared in *Reader's Digest.* The *Graphic* reprint has reached 35,000 circulation. The *Digest* reprint approximates a 300,000 circulation. Here we have a total of nearly 2,300,000. Recently a rough count was made of the circulation of newspapers which carried the gist of the material in news or editorial columns. The grand total runs above 6,000,000.

This article seems to be a "natural" which we are wise to play for all it is worth. The *Digest* reprint (address at Pleasantville, N. Y.) is cheap, light, and small, and so is good for fairly wide circulation. The *Graphic* reprint is fuller in treatment, on better paper, better illustrated, more dignified in appearance. It should impress editors and broadcasters, program committees of clubs, leaders in the community. Single copies, *10 cents,* and *8 cents* down to *5 cents* in quantities.

The picture charts may be displayed at various times and places. In letter size, *20 cents* for the set; 17 by 22 inches, *50 cents.* The larger size should be useful at state conferences of social work, and at many kinds of



From Survey Graphic Magazine, July 1936
Copyright 1936, Survey Associates, Inc.

state conventions. Better add a card telling how to get reprints or charts.

The charts might be reproduced in a monthly bulletin or elsewhere. Before doing so please write for permission and the credit line which should accompany any reproduction. Address: *Survey Graphic*, 112 E. 19th St., New York, N. Y.

" The Health Officer " for November—A good budget of health education material appears in the November, 1936, issue of *The Health Officer*. *Free* from U. S. Public Health Service, Washington, D. C. But we do wish that mechanically it could be made more legible. There is too much of too small type; too much space between letters and between words; italics, on page 235; many of the lines too long for the size of the type.

" Posters Picture Public Health " announces a group of posters produced by the Federal Art Project, W.P.A., New York City. These silk screen posters come through Dr. W. H. Runcie, Board of Health, Hempstead, N. Y. *10 cents* each; less in quantities.

" The Press and Poliomyelitis " is a careful review of newspaper clippings received last summer reporting use of Armstrong-Harrison nasal spray in an outbreak in several southern states. The article might well furnish material for a special memorandum to editors in a like situation.

" Publicizing Public Health," by Dr. C. C. Slemons explains the expanded program of Michigan State Department of Health. Says Dr. Slemons:

When public opinion gets in step with the expanding public health program, then will practical application of public health service be more nearly correlated with current scientific knowledge. Thus arises the urgent need for a concerted effort on the part of public health agencies not only to inform a passive public of the negative values of disease prevention and of positive health measures, but to carry forward the story of public health that the public will actively demand the best possible health protection for every individual.

Recognizing this passive attitude toward public health and the immediate need for active coöperation, the Michigan Department of Health inaugurated this year an educational news program designed to maintain a continuing contact with the public in the interpretation of public health activities and conditions. A full-time trained journalist has been placed in charge of publications and a news service established under the administration of the Bureau of Education. Through this bureau, then, is correlated all news releases to both the lay and the professional press pertaining to the activities of the various administrative bureaus of the department and to local health conditions, as well as all literature designed for positive health education.

One feature of this program is

A series of news releases sent out each week to more than 400 daily and weekly newspapers of the state. In addition, these articles are sent to all of the full-time health officers of Michigan, to the *Michigan Municipal Review*, and to the established news syndicates in the state. The number of articles each week varies from one to several, but it has been found that better coverage is obtained by concentrating upon a single effective release. Every effort is made to meet special requests from editors and from daily reporters for " feature " articles concerning the policies and program of the health department. More timely news " breaks " are released immediately to the daily press through the capitol press bureau.

These articles are written for the newspaper-reading public in the typical news fashion—brief, timely, simply told, and as interestingly written as possible. Naturally, since they interpret state-wide health conditions, the articles are broad in scope, and, hence, lose some of the local appeal that an editor may demand. This is offset to some extent through the coöperation of the local health officers who are urged to correlate local data with our releases in making them more newsworthy for the local press.

The sending of these news releases to the local health officer serves a two-fold purpose. Not only are we providing him with materials and ideas for publicizing the health program, but we are also building for a

cordial relationship between local and state departments. Since the foundation of any public health service lies in the direct services rendered by the local health department, the cause of public health will be advanced to the degree that we can aid such departments and stimulate a demand for a trained health organization in every community.

" A Story of Yellow Jack " tells of a Memphis revival of the professional play, "Yellow Jack," and reproduces a newspaper article used in the promotion of the play.

The Industrial Nurse Teaches—The nurse in industry may do an extensive teaching job as outlined by Lucy DeMuth in " Health Teaching in the Small Industry."

Then there are bulletin boards for the nurse to utilize:

Bulletin boards throughout the plant may be used for safety instruction, while those in the dressing-rooms may be concerned with matters of health. The use of bulletin boards is of particular advantage where women are employed. The supply of material for this purpose is almost limitless. It can include every subject from the care of the hair and the nails to the latest research on cancer. Excellent articles appear almost daily in our current magazines, nursing literature, and newspapers. Very often they are lengthy and written in terms difficult for the average shop worker to interpret, but they can be excerpted or rewritten in a simpler form.

Many organizations throughout the country distribute without cost pamphlets and bulletins on health. Pamphlets that are too lengthy may be kept in the first aid room to be distributed to interested individuals. A list of this reading material may be kept posted on the bulletin board. To create interest in health information the employees may be encouraged to bring in articles they have found interesting. If these have news value, they can be placed on the board for others to read.

What the Newspaper Syndicates Offer—Some 21 writers of newspaper health columns are reported in *Editor and Publisher Thirteenth Annual Directory of Features.* The authors, as listed: Dr. Louis Berg; George W. Crane; Dr. Edmund B. Chaffee; Dr. Cutter; J. J. Gaines, M.D.; Marie Craig, R.N.; Jane Stafford; Dr. Morris Fishbein; Dr. Sophia Brunson; Dr. Logan Clendening; Laurie (health exercise); Dr. Iago Galdston; Dr. William Brady; Dr. Louis E. Bisch; Dr. Foster D. Snell; Dr. Major G. Seelig; Dr. James W. Barton; Dr. James Barton; Dr. C. N. Crisman; Dr. Royal S. Copeland; Beulah France (" Your Nurse Says "). *Editor and Publisher,* Times Bldg., New York, N. Y. Sept. 26, 1936. *10 cents.*

" Great Pox " in Time—Under this heading is reported Dr. Parran's becoming president of " that ancient and honorable organization " which " convened for its 65th annual meeting " in New Orleans—the A.P.H.A.

The article traces syphilis in the

Second Commandment, and down through the ages until in 1929 the St. Louis *Post-Dispatch* "specifically mentioned syphilis in a report of a St. Louis meeting of the National Society for the Prevention of Blindness." Then follows recent history. But

> Nowhere is this taboo more rigidly enforced than on the screen or in radio. Cinema producers are well aware that any reference to the subject, regardless of good motives or public purpose, will only make trouble for themselves. Columbia Broadcasting will not permit the word "syphilis" to go out over the air from its stations. National Broadcasting this year gingerly permitted Dr. Parran and two other authorities to mention the word in broadcasts.

Portraits of Dr. Rice and Dr. Parran accompany this article in *Time,* 350 E. 22d St., Chicago, Ill. Oct. 26, 1936. *15 cents.*

Health Education in September Journal—The September, 1936, issue of *American Journal of Public Health* contained material of value to health educators.

"Administration of Health Education and Health Supervision in Negro Colleges," by Cornely (pages 888–896).

"What Is the Air Hygiene Foundation?" (page 896) announces a new source of background material. The address was not given.

"Milwaukee's Well Advertised Gastrointestinal Epidemic," by Koehler, pages 921–923, gives the facts about "one of those situations."

"A Great Medical Library," editorial, pages 930–932, is something for all readers to go over. Some newspaper editorial writers would appreciate receiving copies of such material.

"Poliomyelitis," pages 933–934, gives background data likely to be of value.

In "Books and Reports," note comments on "Vitality," page 942, and on "That Balanced Diet," page 947.

"A Selected Public Health Bibliography" includes two paragraph titles, page 950: "Unpleasant Thought-of-the-Month," and "Viewers-with-Alarm Please Note."

Do You Tell Them What You Like?—Why are easily named radio favorites so well paid for their broadcasting? Because so many people wrote, or telephoned, or telegraphed their appreciation.

Why are various men and women permitted to buy and use radio time for broadcasting dubious health information or advertising doubtful or dangerous remedies or treatments? Because so few people have taken the trouble to object to these most dangerous of "public enemies."

Light on the above and on other aspects of "The Art of Pleasing Everybody," via radio, will be found in an article so named in *Atlantic Monthly,* 8 Arlington St., Boston, Mass. Oct., 1936. *40 cents.*

Stream Pollution Exhibit—Executed by a window display firm from designs by staff members, the Washington State Department of Health, Seattle, produced an effective display which has been shown at fairs and expositions.

As described by Dr. A. S. Baker, health education adviser:

> The length is 13 feet over all and the height is 8½ feet. The box containing the scene is about 8 feet long, 2½ feet high, and 2½ feet deep.
>
> The scene depicts a mountain background, a city middle ground, and two farms in the foreground, with a stream of running water as a front border (does not show in the picture). In the center a bridge and to the left of this, a pipe (the outfall of the city sewer into the stream) with a sign "Keep Away, City Sewer."
>
> The water in the stream flows from right to left in a metal trough painted to look as natural as possible and containing gravel and pebbles. There is a division in the trough under the bridge to keep the clear water in

the upper end of the stream (right hand side) from mixing with the stained water (representing sewage) in the lower part of the stream (left hand side). The water is kept circulating by two pumps driven by an electric motor mounted under the box. When in operation the two streams appear to mix at the bridge, the outfall sewer pipe pouring its stream of stained (brown ink is used as stain) into the stream at this point. The right hand farm where the water is clear looks prosperous and healthy; the left hand farm is dilapitated, run down, and deserted.

The front panels are finished with dark green fabricoid and the lettering is sawed-out-block in white.

Dr. Baker will loan a photograph to show the general effect.

Child Health and Health Education—One of the educational services of the American Child Health Association was the preparation of carefully classified and annotated reference lists to suggest some sources of reliable, helpful and inexpensive material on various aspects of school health work. This particular service will be continued during the coming year.

The lists are organized in relation to problems confronting administrators, supervisors, teachers, physicians, nurses, and others engaged in school health education.

Single copies of mimeographed or printed reference lists are available to these leaders free of charge. Address: School Health Education Service, 1201 16th St., N.W., Washington, D. C. A set, or individual lists will be sent on request.

"Health Education in Elementary Schools." Mimeographed. Revised. January, 1936. 6 pp. Procedures outlined, references given for specific steps in the development of health education activities in the classroom.

"Health Education—A Brief Bibliography for Administrators and Instructions of Health Education in the Junior and Senior High Schools." Mimeographed. Revised. March, 1936. 5 pp. Contains classified, annotated references including recent articles in professional periodicals.

"Some References on Child Care and Training." Mimeographed. Revised. June, 1936. 6 pp. Prepared for instructors of child care classes in secondary schools and for Parent-Teacher groups.

"Some References on the School Lunch." Mimeographed. January, 1936. 5 pp. An annotated list of references classified under the following headings: general references; organization and management; educational uses of the school lunch; the school lunch and the relief program.

"Health Plays for School Use." Mimeographed. Revised. January, 1936. 6 pp. An annotated list of plays selected with reference to age groups.

"Health Education in the Rural School." Mimeographed. January, 1936. 6 pp. Selected list prepared especially for teachers and parents in rural communities.

In general these lists are suggested as models for consideration by all who make up lists of reading references. The form of the references, and the types of information given will be helpful for a half dozen references, or less, as well as for the extensive bibliography.

The present editions of the child health bibliographies lack some street addresses which might easily have been included. Also there is some needless mention of Government Printing Office in addresses for government publications.

(The inclusion of street addresses is suggested: (1) to cut down the cost of government; (2) to save time in the delivery of mail; (3) to make more sure the correct delivery of mail to some addresses.)

BOOKS AND REPORTS

Cash Relief—*By Joanna C. Colcord. New York: Russell Sage Foundation,* 1936. 263 pp. Price, $1.50.

This book is a genuine contribution in the field of social work since it presents facts concerning a much discussed subject. There has been a growing belief that cash relief was to be preferred to commodity relief, but there were no data available in the United States to substantiate that opinion. Miss Colcord has supplied the facts.

In her search for evidence Miss Colcord made a study of the growth of cash relief since 1930. This was done through a searching analysis of the systems of cash relief in Baltimore, Cleveland, Denver, Detroit, Los Angeles, New York City, Philadelphia, Pittsburgh and San Francisco.

This study has dissipated the fear among social workers and laymen that there would be a misuse of cash grants, resulting in frequent demands for more aid and a refusal to take work when it was offered. The evidence favors cash relief and reveals many of the abuses connected with the order system in which there is overcharging, discourteous treatment, the sale of inferior merchandise, and short weights in many instances. It is possible for the client under the cash system to take advantage of sales and select better food in keeping with his cherished food habits. The Relief Administration favors cash relief since it reduces office expenses and the number of complaints, and leaves more time for the professional staff to make investigations and create a desirable client-visitor relationship.

Human nature is the chief value in social work. There is much concern over the effects of relief of any kind on the mental health of the client. This study provides facts that may be used in considering the mental as well as the physical health of the client. The trained worker realizes that he has not succeeded with a client unless he leaves the client thinking well of himself. Cash relief helps to maintain self-respect. Commodity relief provides an opportunity for merchants to play with self-respect. There is nothing quite so important in the life of the person as his own opinion of himself.

This study can serve as a point of departure for further research in which case studies can be made regarding the effect of the various methods of relief on the human nature of the client.

L. Guy Brown

Official Report of the Sixth National Training Conference of Scout Executives of the Boy Scouts of America, *New York,* 1936, 990 pp.

The commission report on health and safety, embodied in these transactions, is of interest to public health workers. The Boy Scout program reaches over a million boys and approximately 230,000 volunteer leaders every year. An actively functioning, properly organized and adequately trained Health and Safety Committee is the minimum expected of a local Boy Scout Council in the performance of its responsibilities. Coördination of this work with other community health activities is planned. Emphasis is given to the importance of using pasteurized milk in camps. If pasteurized milk is not available, it is suggested that some substitution such as powdered or canned milk be used rather than take the risk involved in the use of raw milk. Belief is re-

affirmed as to the necessity for a thorough physical examination for every boy entering the movement. Suggestions are made for the further constructive development of education in personal hygiene, public health, safety and first aid. IRA V. HISCOCK

Security Against Sickness—*By I. S. Falk. Garden City, N. Y.: Doubleday Doran.* 423 pp. Price, $4.00.

In the current controversy over the social security issue, both those who favor and those who oppose social insurance programs in the United States point to the results of European experience in support of their claims. It is also contended by both sides that American social security programs, as embodied in the "Social Security Act" or the "Majority Report of the Committee on Costs of Medical Care," have ignored the results of such experience. In light of such contentions the volume reviewed here should provide a most welcome addition to the literature on this subject. Dr. Falk's experience in the field of public health, his work in connection with the researches of the Committee on Costs of Medical Care, and his wide familiarity with European programs of sickness and health insurance eminently qualify him for this authoritative survey of health insurance programs abroad and their interpretation to the American public.

The book is divided into 3 parts. In the first and introductory part the author deals with the need for group payment of medical costs in the United States. He points out that group payment is no new venture even in this country, where it exists in the form of charity, the sliding scale of the physician, in the form of taxation, or even in insurance. The issue is not, then, the individual fee system *or* the group payment plan, but rather the extent to which group payment shall develop and the form which it shall take.

The second part of the book is devoted to a detailed analysis of the administration, organization, and costs of health or sickness insurance in Germany, Great Britain, France, and Denmark. These countries were chosen because their programs have been developed to suit widely varying conditions, because they have served as models for many other countries, and because they represent divergent approaches to the problem of sickness insurance. Perhaps the most significant conclusion to be drawn from the whole study is the wide degree of satisfaction felt in each country with its insurance program, in spite of frank admissions of many weaknesses and deficiencies. This, to some, may seem surprising in view of the contention of a number of critics in this country, that health insurance is not popular where tried and that there is increasing sentiment in favor of its abandonment.

In no country did the author find any strong sentiment in favor of the scrapping of a program once started. This seemed also to be the prevailing sentiment of the physicians, as voiced by the leaders in the profession. Instead, it was found that insurance schemes, once started, tended to expand, both as to the extent of the population covered and in the benefits and services provided.

Another significant trend was the tendency for compulsory to replace voluntary social insurance. Even in Denmark the system is voluntary only in name. Important also, in view of the cry in this country of "state medicine" or "public medicine," was the fact that in not a single country studied was there a drift toward "state medicine" if by that term is meant that the state goes into the business of providing medical services to the public. Dr.

Falk finds, on the contrary, that: "There can be no doubt, however, that health insurance has operated to strengthen the position of the private practice in the insurance countries" (p. 286). In the matter of preservation of the personal relation between physician and patient, free choice of physicians, control by the physician of the professional aspects of the insurance program, and maintenance of the highest professional standards, the physician in the health insurance countries seems to occupy a position of wide independence.

In part 3 of the book, the author attempts to draw some lessons for an American program from European systems as well as from our own experience with workman's compensation legislation. In the last 2 chapters he states the case for compulsory as opposed to voluntary insurance and lays down 19 principles as the basis for an American system of health insurance. The writer feels that compulsory rather than voluntary insurance offers the greatest promise for success. He advocates the divorcing of cash payments from medical service. He believes that health insurance should be extended to all parts of the population to which the costs of medical care and loss of income due to illness are likely to prove a serious economic hazard. The basic problem for solution, as seen by the author, is how to transform costs which cannot be budgeted by the individual, and are likely to prove beyond his ability to pay, into costs which can be budgeted by large groups of people over periods of time, and hence fall well within the individual's ability to pay. Compulsory programs of health insurance, developed by the states with financial assistance and standardizations by the federal government, seem to offer the best solution to the problem.

C. T. PIHLBLAD

Heart Disease and Tuberculosis—*By S. Adolphus Knopf, M.D. Livingston, N. Y.: Livingston Press,* 1936. 108 pp. Price, $1.25.

A glance at the table of contents of *Heart Disease and Tuberculosis* will reveal the scope of this brochure. It epitomizes a life-long experience in dealing with the interrelationships of heart disease and tuberculosis. With 53 figures as illustrations, with 29 major chapter headings and an index, all compressed into 108 pages, it can be readily understood that the author could only cover so broad a subject in staccato paragraphs.

It is a matter of interest that the book was issued by the patients of The Potts Memorial Hospital, and it is for sale through them by The Livingston Press, Livingston, N. Y.

KENDALL EMERSON

Industrial Dust—*By Philip Drinker and Theodore Hatch. New York: McGraw-Hill,* 1936. 316 pp. Price, $4.00.

A bibliography rich in material, United States and foreign, forms the basis of this new book in the field of industrial hygiene. The authors have drawn freely from their own researches and the literature for a sound exposition of the hygienic significance, measurement and control of industrial dust, perhaps the most valuable contribution on this particular subject thus far, especially in the light of present-day agitation for more adequate and proper legislation for the protection of the industrial worker exposed to harmful dusts, the numerous law-suits in which questions pertaining to exposure of employees to dusts and sanitary control of the industrial environment are involved, the increasing interest in the teaching of industrial hygiene, the establishment of divisions of industrial hygiene in state departments of health,

and the many controversial points on the subject being discussed by industrial engineers and physicians.

Coöperation between the physician and the engineer is fundamental in the control of industrial dust hazards. " Design of dust control apparatus is an engineering matter but it is often the physician who finally appraises the success of the control system." With this prefatory statement the authors include in their book chapters on the effects of dusts and fumes upon the human organism, physical and chemical factors in pneumoconiosis, permissible dustiness, and medical control of the dust hazard. The medical aspects are given in order to " help the engineer to understand the manner in which hygienic requirements affect engineering design and operation of dust-control equipment." The book is none the less valuable for the industrial physician, who should be acquainted with the engineering aspects of dust control if he is to understand better and intelligently pass upon the adequacy of the plant's efforts to improve the industrial environment of the worker exposed to harmful dusts and fumes.

In keeping with latest thoughts in the matter of disabling illness due to dust the authors state there is no reason, medical or social, for branding a man with first-stage silicosis as disabled because of the serious harm that may thus be done to both industry and the man, inasmuch as the man is thereby prevented from seeking gainful occupation, and the employer, by hiring such a man, opens the door to suits involving the slightest mishap to the " disabled." It is pointed out that in the British Empire, where silicosis legislation has been in force for some years, only the man with advanced silicosis, simple or infective, is considered disabled.

Permissible dustiness is given for quartz, coal dust, cement and limestone, lead, zinc oxide, manganese; but, according to the authors, there is no authoritative available data which would justify the adoption for medicolegal purposes of standards of permissible dustiness for each harmful dust. Standards may be used as " basic criteria in the design and operation of dust control equipment and as general guides in the appraisal of working conditions," but the authors conclude the use of these figures for medicolegal considerations is unsound because of the limiting factors of mineralogical composition, " dust floods," and industrial selection, involving the process of natural selection of the fittest and the continuous elimination from industry of the unfit.

Pages 80 to 166 give methods of analyzing the extent of dust hazards, including the dust survey, determination of dust concentration, determination of particle size, chemical and mineralogical analysis of dust. Extremely useful information is given for the laboratory worker.

A short chapter on Methods for the Control of Industrial Dusts is divided into 2 parts: (1) environmental or engineering control, (2) personal or medical control. An appeal is made for initial physical examinations and periodic examinations thereafter. Engineering control is divided into 3 groups: eliminating the sources of dust, preventing the dispersion of dust at its source, and providing individual protection.

The book describes the principles and design of local exhaust systems, air-cleaning apparatus, air filters, and finally there is a historical review of the use of dust respirators and air masks, including the methods of testing respiratory protective equipment and filter materials.

The book is well illustrated; its

tables and figures are clear and well edited; and the bibliography is comprehensive. The authors have provided name and subject indices.

The reviewer commends the volume to the industrial physician, the industrial engineer, the industrial hygienist, the industrial nurse, the safety engineer, the public health laboratory technician, the teacher in industrial hygiene in the medical school, and the school of public health, and the health officer.

BERNARD S. COLEMAN

The New Healthy Living—*By C.-E. A. Winslow and Mary L. Hahn. New York: Merrill,* 1935. Book I, 332 pp. Price, $.84. Book II, 460 pp. Price, $1.00.

Among the early health books for classroom use on the market was the New Healthy Living series which was received enthusiastically by teachers and health educators, because they were prepared by two individuals who knew the proper approach in the health education field. Professor Winslow offered the rich health education background and Miss Hahn the successful teacher's ability to select the right material and present it in an interesting, appealing fashion to school children.

After 6 years of success in the supplementary textbook field this series has been revised. The books are very readable for the age of children for whom they were prepared. Simple experiments that can easily be tried in the classroom, anecdotes of famous persons whose success has been achieved by recovered health, the importance of health in every line of service and activity, simple treatment of communicable disease problems, community and home sanitation, state and federal health supervision and services are only a few of the subjects that intrigue the adolescent readers to go on from chapter to chapter.

Physiology is introduced and the subject of mental hygiene is very pleasingly handled. So when they close the books they are ready to put a high valuation on health, concretely and abstractly. Many fine illustrations, an index in both books and a glossary in Book II also make for the excellence of these school books.

ANNA B. TOWSE

Idols and Invalids—*By James Kemble, Ch.M., F.R.C.S. New York: Doubleday, Doran,* 1936. 328 pp. Price, $3.00.

The ills of the flesh are always interesting when they are the ills of famous persons. In this well printed book a Fellow of the Royal College of Surgeons diagnoses the ailments and performs post-mortems on a score of the most celebrated figures in history. He does it exceedingly well, for he has a pleasing style, in which he deftly mixes philosophy with fact, and medicine with history. In Great Britain the book was published under the somewhat apt title, "Hero Dust."

The narratives begin with a study of Lord Byron, whose personality was acutely affected by his lameness, and end with Omar Khayyam, the Persian poet who was a centenarian in the hazardous 12th century. In between, the author describes the medical and psychological histories of Columbus; Judge Jeffreys, whose sufferings from stone led to the Bloody Assizes; Louis XV, and his procession of mistresses; the baleful Borgias; Cleopatra, the brilliant product of centuries of inbreeding; Lord Nelson, the perpetual invalid; Henry VIII, the syphilitic; Queen Anne, the ugly; and Mary Queen of Scots, the comely; Epicurus, the epicurean; the amatory Catherine the Great; John Milton, who was not always blind; and Beau Brummel, who lived for a while in elegance and died in misery.

In the preparation of this interesting book the author has had access to many rare documents. The facts presented seem accurate, and the conclusions drawn from them are reasonable, with one noteworthy exception. The author asserts the generally discarded theory that syphilis originated in America and was brought to Europe by Columbus and his crew. Most authorities seem agreed today that the red plague had existed in mild form in Europe long before the celebrated explorer discovered America and the charms of the diseased maidens of Hispaniola.

Although the general reader will encounter in this enjoyable book occasional words and phrases that are more or less typical of the obscurant terminology employed by medical writers, he will find the book a most entertaining and enlightening one. The sanitarian should find it fascinating.

JAMES A. TOBEY

Slim and Supple—A New System of Swedish Exercises for Young and Old—*By Barbro Leffler-Egnell. New York: Appleton Century,* 1936. 209 pp. Price, $2.00.

This text offers a system of Swedish exercises for women, designed to accomplish the purpose indicated in the title.

This is another of the texts on exercises designed basically to reduce weight and restore the "girlish" figure. The text is profusely illustrated with pictures of the various exercises. The directions are clear. To the layman the purpose of some of them would not be apparent. The specific aim and purpose of each exercise should have been mentioned in connection with each exercise. This has been done in some cases.

Some of these exercises are difficult to do in good "form" unless given under definite personal instruction and careful supervision. Some, especially if unsupervised, would tend toward sacroiliac strain. CHARLES H. KEENE

British Masters of Medicine—*Edited by Sir D'Arcy Power. Baltimore: Wood,* 1936. 242 pp. Price, $3.00.

Close in the wake of *Great Doctors of the Nineteenth Century* comes this other book of biographical sketches confined entirely to the British.

Beginning with Harvey (1578–1657), sketches of a number of men who have made outstanding contributions to medicine down to and including Ernest Henry Starling (1866–1927) are given. The sketches have been written by those who have been attached to the institutions which their heroes made famous. They appeared originally in the *Medical Press and Circular* in a series of articles carrying the same title as the book. They have now been collected in one volume and arranged in chronological order with some additions and minor corrections.

This book has the peculiar value of calling to our attention some names which are all but unknown to the general profession as well as to the public. Notable among these, for example, is Sir John Floyer, who was the first man to count the rate of the pulse and respirations by the minute, having invented what he called the "Pulse Watch" for the purpose. He was also the first to estimate the blood volume and compare it with the body weight, the results being remarkably near to those obtained by modern methods. He also tried a number of very ingenious experiments, was the first to describe emphysematous change in the lung, and to show that spasmodic asthma was due to constriction of the bronchi. His biographer states very properly that his work has never been sufficiently recognized, even in England.

The book is well written and unusually well illustrated. It deserves a place in the library of every physician.

MAZŸCK P. RAVENEL

Quarterly Bulletin of the Health Organisation of the League of Nations, Vol. V, No. 1 (Mar.), 1936.

This issue of the *Quarterly Bulletin* is unusually interesting as it gives a valuable report of the Pan-African Health Conference held November 20 to 30, 1935. While a little late in publication, the material is of great value. There are special reports on yellow fever, plague, malaria, typhus fever, animal diseases communicable to man, etc.

The report on yellow fever is particularly interesting, giving historical reviews of yellow fever in Africa and South America. Perhaps the most striking report is that on jungle yellow fever. There is a special report on yellow fever in West Africa.

Another section is devoted to insects in aeroplanes, on which our own Public Health Service has done valuable work. Bubonic plague is well considered at some length.

The report on animal diseases communicable to man deserves attention. It is apparent that bovine tuberculosis is spreading with considerable rapidity in certain parts of French West Africa and the British Cameroons, and in Northern Rhodesia a very large percentage of the cattle is affected.

There has been no proof in South Africa that bovine tuberculosis is responsible for human cases, though the disease in cattle is just as virulent as in other countries, and the reporter, Dr. P. J. Du Toit, recognizes the transmission which has been proved in other countries.

Altogether, this number of the *Bulletin* is of unusual interest and is worthy of close study.

FACING THE FUTURE WITH THE CHARACTER BUILDING AGENCIES. By Arthur A. Schuck. Prepared by National Character Building Agencies in coöperation with the 1936 Mobilization for Human Needs. Distributed by Community Chests and Councils, Inc., 155 East 44th St., New York, N. Y. 32 pp. Price, $.10.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

All about Hormones — Intended for the educated laity, this review of present knowledge of the functions of the ductless gland will enlighten all sanitarians, except the few who know about physiology.

COLLIP, J. B. Hormones. Sci. Month. Nov., 1936, p. 411.

Ascertaining Effectiveness of Disease Control Measures—Putting specific tuberculosis control methods to statistical tests is essential if a public health program is to be evolved which will be both flexible and efficient.

DOWNES, J. A Study of the Effectiveness of Certain Administrative Procedures in Tuberculosis Control. Milbank Mem. Quart. 14, 4:317 (Oct.), 1936.

Telling the Public—An excellent series of discussions for the lay public on diabetes, appendicitis, sight conservation, poliomyelitis, colds, sleep, quacks, medical problems, etc., conducted by the New York State Medical Society.

EPSTEIN, A. A. *et al.* What the Community Should Know about Diabetes, etc. New York State J. M. 36, 18:1322 (Sept. 15), 1936.

Water Analysis Discussed—As it is possible that typhoid bacilli may persist longer than organisms of the coli-aerogenes group in water treated with chlorine, the authors suggest the reconsideration of the significance of the latter organisms as a standard of safety.

HEATHMAN, L. S. *et al.* Resistance of Various Strains of E. Typhi and Coli-aerogenes to Chlorine and Chloramine. Pub. Health Rep. 51, 40:1367 (Oct. 2), 1936.

Our Knowledge of Poliomyelitis—Compared to other communicable diseases, polio is not an important cause of death. For the present, a successful vaccine is not available and chemical prophylaxis is decidedly in the experimental stage. About the only preventive measures for susceptible ages are: abstaining from unnecessary contacts during epidemics; guarding against excessive strain; reporting suspicious illnesses.

LEAKE, J. P. Poliomyelitis. J.A.M.A. 107, 14:1094 (Oct.), 1936.

Nutritive Values of Raw and Pasteurized Milk—Nutritionists will want to know about this study even though the results seem not of practical importance. Third generation rats fed pasteurized milk and wheat showed evidence of vitamin deficiency not found in rats fed raw milk and wheat.

MATTICK, E. C. V., and GOLDING, J. Relative Value of Raw and Heated Milk in Nutrition. Lancet 2, 12:702 (Sept. 19), 1936.

More Trichinosis Than You Suspect—Examination of muscle tissues taken from random autopsies in California (none of the patients ever having shown clinical signs of trichinosis) revealed a 24 per cent infection of Trichinella spiralis. The author reminds us that under present methods of meat inspection, the consumer must assume the responsibility for thorough cooking of all pork.

MCNAUGHT, J. B., and ANDERSON, E. V. The Incidence of Trichinosis in San Francisco. J.A.M.A. 107, 18:1446 (Oct. 31), 1936.

The Cinderella of Medicine—Cautioning health authorities not to neglect gonorrhea in their renewed drives for the control of syphilis, this author breaks down reported cases into age and sex groups which are significant guides to the application of preventive measures.

NELSON, N. A. Gonorrhea. Milbank Mem. Quart. 14, 4:328 (Oct.), 1936.

As Others See Us—Our hodgepodge of local health administrative units is observed by a British sanitarian. His findings prove a good antidote to any delusions of grandeur from which we may suffer.

PICKEN, R. M. F. Public Health in the United States of America. Brit. M. J., 3951: 631 (Sept. 26), 1936.

Vitamins and Infection—Dogs fed a diet deficient in vitamin B appeared to be more susceptible to artificial infection with *S. aureus* and lost twice as much weight after infection as did the control animals.

ROSE, S. B., and ROSE, W. B. Bacterial Resistance in Vitamin B Deficient Dogs. J. Infect. Dis. 59, 2:174 (Sept., Oct.), 1936.

What to Do About Heart Diseases—Half or more of all cardiac cases are among the elderly. What to do about the other cases caused by syphilis, rheumatic fever, etc., is discussed for the benefit of the public health nurse, but the paper has something in it for every health worker.

SAMPSON, J. J. Heart Disease as a Public Health Problem. Pub. Health Nurs. 28, 10:637 (Oct.), 1936.

International Vital Statistics—As a fairly reliable indication of the sanitary, medical, and social progress of a nation, this author presents an interesting study of the "natural" deaths compared to the total deaths in a number of countries. The United States enjoys a favorable position.

SAND, R. Changes in the Death Rate Since the Seventeenth Century. Milbank Mem. Quart. 14, 4:311 (Oct.), 1936.

ASSOCIATION NEWS

THOMAS PARRAN, M.D., PRESIDENT
ARTHUR T. McCORMACK, M.D., PRESIDENT-ELECT

AT the Sixty-fifth Annual Meeting of the American Public Health Association in New Orleans, November 20–23 Walter H. Brown, M.D., of Stanford University, Palo Alto, Calif., retired from the office of President, and Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, became President for the year 1936–1937. The new President-Elect is Arthur T. McCormack, D.Sc., LL.D., M.D., D.P.H., State Health Commissioner of Kentucky.

Arthur T. McCormack was born in Nelson County, Ky., August 21, 1872, the son of Dr. Joseph Nathaniel McCormack and Corrine Crenshaw. In 1893 he entered the College of Physicians and Surgeons, Columbia University, New York, from which he received the degree of M.D. in 1896. Detroit College of Medicine and Surgery made him a D.P.H. in 1925; Berea College gave him a D.Sc. in 1926; Transylvania College conferred an LL.D. in 1930.

He began practice at Bowling Green, Ky., in 1897, and was shortly thereafter appointed Health Officer of Warren County. From 1898 to 1912 he served as Assistant State Health Officer of Kentucky. Since 1912 he has been continuously State Health Officer or State Health Commissioner and Secretary of the State Board of Health.

He was Surgeon General, Kentucky National Guard, 1900–1908; Lieutenant, Medical Reserve Corps, U.S.A., 1911–1917; promoted to Major upon the entrance of the United States in the World War in 1917, and organized

Dr. Arthur T. McCormack

Base Hospital Number 59. When about ready to proceed overseas, he was ordered to Panama as Chief Medical Officer of the Canal Zone with the grade of Lieutenant Colonel. He completed construction of the Ancon Hospital and controlled an epidemic of cerebrospinal meningitis on the Japanese S. S. Anyo Maru, for which he received the personal thanks of the Mikado.

In 1901 he founded the *Kentucky Medical Journal,* of which he has since been editor and a director. He organized and served as Dean of the School of Public Health, University of Louisville; Secretary of the Kentucky State Medical Association for the past 26 years; is a member of the Gorgas Memorial Institute; member of the National Health Council; Fellow of the American College of Surgeons; member and officer of the American, Kentucky, and Jefferson County Medical Associations; Past-President and Secretary of the Medical Veterans of the World War; Past-President of the Conference of State and Provincial Health Authorities of North America; Past-President of the Kentucky Conference of Social Work; and is now Chairman of the Kentucky Social Security Commission.

Originating the idea of administering public health in rural communities through local full-time health departments, with the county as a unit and operating under the supervision of a central authority, Dr. J. N. McCormack, his father, did the pioneer work in promotion of this idea and lived to see several full-time county health units successfully functioning in his state.

Dr. Arthur T. McCormack has carried the work forward so well that today not only three-fourths of the total population of Kentucky have whole-time public health administration, but fully one-fourth of the people in rural communities in the United States and a large proportion of those in Canada are enjoying health protection furnished by local full-time health departments patterned after the Kentucky model.

Dr. McCormack has been a member of the A.P.H.A. since 1919, was made a Charter Fellow in 1923, and is a Life Member.

DR. CUMMING ELECTED AN HONORARY FELLOW

DR. HUGH S. CUMMING, the former Surgeon General, was made an Honorary Fellow of the American Public Health Association at the recent New Orleans Annual Meeting. Dr. Cumming's accomplishments in the public health field are so outstanding and so numerous that this is an honor he richly deserves.

TRIBUTE TO MEMBERS OF LONG STANDING

THE presentation of a beautiful certificate to each member who has been affiliated with the American Public Health Association for 40 years or more was an interesting and touching ceremony at the banquet at the New Orleans Annual Meeting. Two of the eight members concerned, namely Dr. John Harvey Kellogg and Daniel W. Mead, were there in person. The certificates for the remaining members who were not able to attend were received as follows: Dr. Mazÿck P. Ravenel for Dr. William C. Woodward; Dr. Henry D. Chadwick for Mr. Robert Spurr Weston; Dr. Henry F. Vaughan for Dr. George A. Soper; Dr. Angel de la Garza Brito for Dr. Jesus E. Monjaras; Dr. Clarence L. Scamman for Dr. Charles V. Chapin; and Dr. Carl E. Buck for Marion Talbot.

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY—NEW AFFILIATED SOCIETY

THE request of the newly formed Public Health Association of New York City for affiliation with the American Public Health Association was accepted at the New Orleans

Annual Meeting. The officers are: *President,* Dr. Donald B. Armstrong; *First Vice-President,* Dr. John L. Rice; *Second Vice-President,* Hazel Corbin; *Secretary-Treasurer,* Frank Kiernan.

The first scientific meeting of this new affiliated society will be held on December 3, 1936, at the George Washington Hotel. The society is made up of those Fellows and Members of the American Public Health Association living in Metropolitan New York City who expressed their desire to become affiliated. At the present time the membership numbers about 300.

DEATH OF ROSS L. LAYBOURN

OUR meeting in New Orleans was marred by one very sad incident. On Monday morning, October 19, Ross L. Laybourn, the Director of the Bacteriological Laboratory of the State Board of Health of Kansas, experienced a heart attack while on his way to breakfast. He soon regained consciousness, was removed to the nearest hospital, and later to a government hospital, since he was a reserve officer in the Army. He died November 10.

Mr. Laybourn was an exceedingly active member of our Laboratory Section. We carried a paper by him, which was to have been read at the New Orleans meeting, in the October *Journal,* it having been requested in advance. He became a member of our Association in 1918 and a Fellow in 1923. He will be greatly missed by his associates of the Laboratory Section and members of our Association in general.

FREE HEALTH SURVEY

A FREE health survey will be granted to some one county or district, and some one city, entered and submitting a schedule in the 1936 Inter-Chamber Rural Health Conservation Contest.

Basis Upon Which Survey Will Be Granted—In order to be eligible for the Free Survey, a county or district, or a city, must submit a fact-finding schedule. The free survey will be granted not upon the score attained in the 1936 Contest but rather upon a combination of the following two factors: (1) The need of the community for a health survey, and (2) the opportunity and likelihood of the community making effective use of such a survey.

For further information write either the Insurance Department, Chamber of Commerce of the United States, Washington, D. C., or the Committee on Administrative Practice of the American Public Health Association.

SCIENTIFIC EXHIBITS AT NEW ORLEANS 1936

ALTHOUGH citations of merit were made for selected scientific exhibits at the Milwaukee meeting in 1935, this year at the New Orleans meeting certificates were conferred for the first time. Four exhibits were chosen by the judges for the award. Judges were: Dr. Guy S. Millberry, Dr. John L. Rice, and Dr. G. Foard McGinnes. The Committee on Scientific Exhibits has already expressed, publicly, its appreciation to the judges for their services in the difficult task with which they were charged. Their decisions were unanimous. To aid them the committee suggested 4 criteria for their guidance.

1. The effectiveness of the exhibit in *attracting attention.*
2. Its effectiveness in *holding attention* long enough to accomplish its purpose.
3. Its *clarity* in expressing its message.
4. Is the message worth while or *pertinent* for presentation to a group of *public health workers?*

In addition the judges were asked to make a brief statement to indicate why

each exhibit was selected. Their selections and statements were:

1. *The American Red Cross* exhibit on Pellagra, because it is wisely confined to a single subject and most attractively presented.
2. *National Society for the Prevention of Blindness,* for the concise, clear, and inexpensive presentation of its important motif.
3. *Sewerage and Water Board of New Orleans,* for a beautifully prepared representation of a local health facility.
4. *The Committee on Administrative Practice exhibit on Health Conservation Contests,* which, clearly expressing its purpose in cleverly worded legends, is limited to one subject eminently appropriate to the occasion.

A number of other exhibits received comment from the judges for particularly interesting items.

It was noteworthy that some exhibits were not entirely appropriate to a public health meeting, or which violated many of the accepted principles of a good exhibit, nevertheless attracted considerable attention from the delegates.

Also, it was specially gratifying to observe the large number of exhibits entered. The hearty thanks of the Association are due all exhibitors for their expenditures of time and effort toward making so creditable a contribution to the annual meeting.

BACK NUMBERS OF JOURNAL NEEDED

DUE to unusual demands for the following numbers of the *American Journal of Public Health*—

June,	1935
November,	1935
February,	1936

—the Executive Office of the A.P.H.A. has run out of stock on these issues and is in need of as many copies as are obtainable. It will be greatly appreciated if members who can spare these *Journals* will send them to headquarters.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

John A. Carter, M.D., 1301 Washtenaw Ave., Ann Arbor, Mich., Administrator, Clermont County Health Unit (taking course at University of Michigan)

Jose B. Castellanos, Valladolid 55 Bis., Mexico, D. F., Mex., State Health Officer, Veracruz

Julio Cesar Trevino, M.D., Ave. Hidalgo #41, Mexico, D. F., Mex., Chief, Quarantine Central Office, Department of Health

Sambola J. Couvillon, M.D., Moreauville, La., Member, State Board of Health

Walter M. Dickie, M.D., Ph.D., 8 Roble Court, Berkeley, Calif., State Director of Public Health

Thomas M. Fly, M.D., City Hall, Little Rock, Ark., City Health Officer

Alton A. Jenkins, M.D., 4371 Everett St., Oakland, Calif., District Health Officer, Utah (Post Graduate Student in Public Health, University of California)

Abraham I. Love, M.D., 4500 Elston Ave., Chicago, Ill., Health Officer, City Board of Health

Loran E. Orr, M.D., 1402 Washington Heights, Ann Arbor, Mich., District Health Superintendent, Illinois State Dept. of Public Health (taking public health course at University of Michigan)

Carl V. Reynolds, M.D., State Board of Health, Raleigh, N. C., State Health Officer

J. R. Ridlon, M.D., U. S. Marine Hospital, Galveston, Tex., Medical Officer in Charge

Gradie R. Rowntree, M.D., C.P.H., Hickman, Ky., Fulton County Health Officer

Emil A. Steiner, M.D., Somerset, Ky., Director, Pulaski County Health Dept.

J. Leland Tanner, M.D., M.P.H., Henderson, Ky., Director, Henderson County Health Dept.

Paul M. Thompson, M.D., Abbeville, Ala., Henry County Health Officer

Edward L. Van Aelstyn, M.D., 2331 Prince St., Berkeley, Calif., District Health Officer,

Utah (taking public health course at the University of California)

John W. Williams, M.D., C.P.H., City Hall, Asheville, N. C., City Health Officer

Benjamin F. Wyman, M.D., State Office Bldg., Columbia, S. C., Director, Rural Sanitation and County Health Work, State Board of Health

Laboratory Section

John X. Blender, 817 Arch St., Ann Arbor, Mich., Graduate Student, University of Michigan

Mattie Carter, State Hygienic Laboratory, Jackson, Miss., First Assistant Bacteriologist

William W. Cort, Ph.D., 615 N. Wolfe St., Baltimore, Md., Professor of Helminthology, School of Hygiene and Public Health

Mildred Davis, State Board of Health, Jackson, Miss., Bacteriologist, State Hygienic Laboratory

John M. Liptay, 37 Northern Blvd., Long Island City, N. Y., President, Laboratory Furniture Co., Inc.

Orin A. Ogilvie, M.D., 916 Military Drive, Salt Lake City, Utah, Teacher of Bacteriology, Pathology and Immunology, University of Utah

John P. Ransom, 608 Howard St., San Luis Obispo, Calif., Bacteriologist, San Luis Obispo County Health Dept.

Morris Ribner, 421 Flatbush Ave., Brooklyn, N. Y., Bacteriologist, Mt. Prospect Laboratory

Burton T. Simpson, M.D., 113 High, Buffalo, N. Y., Director, Division of Cancer Control, State Dept. of Health

George T. Stevens, U. S. Marine Hospital, San Francisco, Calif., Bacteriologist

Vital Statistics Section

Marjorie W. Amerine, 205 Lasseter St., Montgomery, Ala., Chief Tabulating Clerk, State Board of Health

Clifford H. Greve, 320 S. 7th St., Ann Arbor, Mich., Student

Public Health Engineering Section

Walter D. Bellamy, P. O. Box 301, Huntsville, Tex., District Sanitary Engineer, State Dept. of Health

Andrew T. Dempster, 9355 Wildemere Ave., Detroit, Mich., Assistant Sanitary Engineer, Dept. of Health

Wesley E. Gilbertson, State Dept. of Health, Bismarck, N. D., District Supervisor, Community Sanitation

Wilbert H. Grisham, Rm 105, Court House, Memphis, Tenn., Director, Division of Malaria-Mosquito Control, City Health Dept.

Albert Haneman, Jr., Box 476, Victoria, Tex., District Sanitary Engineer, State Dept. of Health

Chauncey A. Hyatt, Capitol Bldg., Springfield, Ill., Swimming Pool Sanitarian, State Dept. of Public Health

Paul F. Krueger, 707 City Hall, Chicago, Ill., Director, City Division, Bureau of Dairy Products, Board of Health

Harold Lesser, 118 N. Ingalls St., Ann Arbor, Mich., Student

Douglas L. Parker, 161 College St., Wilmington, O., Sanitarian, Clinton County

John B. Thomas, 1601 Ridge Rd., Catonsville, Md., Sanitary Engineer, Land Utilization Division, Resettlement Administration

William H. Weir, State Capitol Bldg., Atlanta, Ga., Assistant Chief, Division of Sanitary Engineering, State Dept. of Public Health

Cranston J. Wilcox, 223 S. State, Ann Arbor, Mich., Student

Industrial Hygiene Section

Theodore F. Hatch, 80 Centre St., New York, N. Y., Associate Dust Control Engineer, Division of Industrial Hygiene, State Dept. of Labor

Siegfried J. Nilson, M.D., D.D.S., 80 Maiden Lane, New York, N. Y., Medical Director, Fidelity and Casualty Co.

Oliver W. Welch, M.D., M.P.H., Tennessee Valley Authority, Wilson Dam, Ala., Associate Medical Officer, Industrial Hygiene

Food and Nutrition Section

Howell A. Smith, 800 West 21 St., Austin, Tex., Field Milk Supervisor, State Dept. of Health

Arthur H. Williamson, D.V.M., State Board of Health, Jacksonville, Fla., State Dairy Supervisor

Child Hygiene Section

Mildred A. Hesser, 117 N. State St., Ann Arbor, Mich., Student

Geneva S. Rothemund, M.D., 514 S. Wittenberg Ave., Springfield, O., Pediatrician, Bureau of Child Hygiene, State Dept. of Health

Lewis K. Sweet, M.D., Box 417, Tahlequah, Okla., Medical Officer, U. S. Children's Bureau

Virginia E. Webb, M.D., 313 New Court House, New Orleans, La., Acting Director, Red River Parish Health Administration

E. Bryant Woods, M.D., State Board of Health, Jacksonville, Fla., Director, Maternal and Child Health Bureau

Public Health Education Section

Etta G. Davis, R.N., C.P.H., 11321 Strathmoor, Detroit, Mich., Nurse Counsellor, Dept. of Health

James E. McCormick, M.D., 322 Clinton Ave., Newark, N. J., Assistant Director, Health Education

Leo H. Mynes, M.D., R.F.D. #3, Box 15, Charleston, W. Va., Medical Director, School Health Service, Kanawha County Schools

Public Health Nursing Section

Pauline Baker, 540 Packard St., Ann Arbor, Mich., Public Health Nurse, Madison County Board of Health (taking course at University of Michigan)

Agnes B. Bowe, 7556 Byron Place, Clayton, Mo., Director, Public Health Nursing Service, St. Louis County Health Dept.

Elsie M. Bowman, 1208 E. University, Ann. Arbor, Mich., Student Nurse

Florence H. Bunton, 6133 Fischer Ave., Detroit, Mich., Supervisor and Coördinator, Generalized Nursing Districts, Dept. of Health

Mildred Cardwell, R.D. #3 Lansing, Mich., Nurse, Ingham County Public Health Nursing Service

Georgie C. Clark, R.N., 416 Avon St., Flint, Mich., School Nurse, Board of Education

Jane D. Gavin, Court House, Durham, N. C., Supervising Nurse, Durham City and County Health Dept.

Hazel C. Holmes, R.N., 408 S. 4th Ave., Ann Arbor, Mich., Public Health Nurse (Student)

Helen F. Kramer, R.N., 755 E. University Ave., Ann Arbor, Mich., Public Health Nurse (Student)

Gladys F. Morehouse, 12703 Northlawn, Detroit, Mich., Special Supervisor, School Nurses

Matie V. Neely, R.N., 2614 West 15, Little Rock, Ark., Assistant State Nursing Supervisor, State Board of Health

Eva Pugh, R.N., P. O. Box 456, Danville, Va., Tuberculosis Field Nurse, State Board of Health

Elizabeth N. Rowland, 540 Packard St., Ann Arbor, Mich., Public Health Nurse, Washington Court House Board of Health (taking public health course at University of Michigan)

Margaret S. Vaughan, State Capitol, Little Rock, Ark., Supervisor, Public Health Nursing, State Board of Health

C. A. Wagner, El Paso Masonic Hospital, El Paso, Tex., Superintendent

Anastasia Wilson, R.N., 108 S. Broadway, Buhl, Idaho, School and County Nurse, Twin Falls County Health Unit

Bertha M. Winne, R.N., 517 E. Main, Marion, Va., Field Nurse, State Dept. of Health

Erma L. Wolfort, R.N., 6145 McPherson, St. Louis, Mo., County Health Counselor, St. Louis County Health Dept.

Epidemiology Section

James C. Boland, M.D., 228 Eighth St., Troy, N. Y., Epidemiologist-in-training, State Dept. of Health

James R. Enright, M.D., 409 Olohana St., Honolulu, T.H., Director, Bureau of Communicable Diseases, Board of Health

Ralph H. Heeren, M.D., Ph.D., 275 Medical Lab. Bldg., Iowa City, Ia., Assistant Professor of Hygiene and Preventive Medicine, University of Iowa Medical College

Ralph B. Snavely, M.D., Office of Indian Affairs, Dept. of the Interior, Washington, D. C., Commissioned Medical Officer, U. S. Public Health Service

Morris A. Stewart, Ph.D., University of California, Davis, Calif., Assistant Professor of Entomology

Glenn S. Usher, M.D., 1208 Tenth Ave. W., Seattle, Wash., Assistant Epidemiologist, State Dept. of Health

Unaffiliated

Ben A. Cohan, 1032 Church St., Ann Arbor, Mich., Student

Rufus Cole, M.D., D.Sc., 66 St. & York Ave., New York, N. Y., Member, Board of Scientific Directors, International Health Division, Roekefeller Foundation

Delia A. Lynch, M.D., 712 World Herold Bldg., Omaha, Nebr.

Edwin M. Mahoney, M.D., 630 Dwight St., Holyoke, Mass., Member, Board of Health

Dr. Felipe Malo Juvera, Alzate 83, Mexico, D. F., Mex., Chief of a Sanitary Brigade, Public Health Dept.

Clifton E. Merritt, M.D., 813 McKinley, Ann Arbor, Mich., Student

William B. Perry, Jr., M.D., 55 Shattuck St., Boston, Mass., Student

Edwin H. Place, M.D., 1608 Geddes, Ann Arbor, Mich., Student

Hanley E. Rosenberg, 1026 Vaughan, Ann Arbor, Mich., Student

Fannie B. Shaw, 50 W. 50 St., New York, N. Y., Secretary, School Health Association, National Tuberculosis Assn.

Milton L. Shurr, 1412 Geddes, Ann Arbor, Mich., Student

Vesta L. Stone, R.N., 12 Grove St., Fitchburg, Mass., Executive Secretary, N. Worcester County Public Health Assn.

Lars W. Switzer, M.D., Spruce St., Manistee, Mich.

Beatrice E. Tucker, 9 S. Michigan Ave., Chicago, Ill., Medical Director, Chicago Maternity Center

Echo D. Watson, Rm 230, State Bldg., Boise, Idaho, Secretary to Director of Public Health

DECEASED MEMBERS

Professor Edwin O. Jordan, Chicago, Ill., Elected Member 1899, Fellow 1922

Dr. Frank G. Atwood, New Haven, Conn., Elected Member 1920

Gordon Hastings, M.D., M.P.H., Little Rock, Ark., Elected Member 1934

Nicholas S. Hill, Jr., New York, N. Y., Elected Member 1910, Fellow 1922

J. C. Perry, M.D., San Francisco, Calif., Elected Member 1915, Fellow 1923

James M. Anders, Philadelphia, Pa., Elected Member 1933

Richard O. Beard, M.D., Minneapolis, Minn., Elected Member 1926

NEWS FROM THE FIELD

SOCIAL HYGIENE DAY

THE first National Social Hygiene Day will be held February 3, 1937, as announced by the American Social Hygiene Association, New York. On this day, state and community voluntary organizations interested in the control of syphilis and gonorrhea, and in other social hygiene problems, with the advice and approval of health authorities and the medical and allied professions, plan to hold meetings all over the United States.

The American Social Hygiene Association will hold its annual meeting on February 3 and the Social Hygiene Council of Greater New York will hold its Fifth Annual Regional Conference. It is expected that public leaders, including Surgeon General Parran, President Ray Lyman Wilbur, of Stanford University, President of the American Social Hygiene Association and former Secretary of the Interior, will speak at these meetings. National agencies and many of their state and community organizations which include social hygiene activities in their yearly programs are planning to participate. It is probable that a nation-wide radio hook-up will provide addresses of importance from government officials and civic leaders in different parts of the country as a climax to the activities of the First National Social Hygiene Day.

There has been definite progress all along the line during the past year in public understanding and support of the campaign against syphilis. Newspapers and magazines are opening their columns to public discussion of this health menace to a greater extent than ever before.

It is believed that the direction of united nation-wide attention to this subject in the way that is proposed will help professional and lay community leaders to capitalize and increase this new interest, and consolidate for further advances toward meeting Dr. Parran's challenge to " stamp out syphilis."

FLORIDA TUBERCULOSIS BUREAU

THE Florida State Department of Health has established a Tuberculosis Bureau, with Dr. Arthur J. Logie, of Chattahoochee, as Director. One of the first activities of the Bureau will be a survey to determine the need for clinics throughout the counties.

A mobile laboratory will be operated in sections not cared for by county health units.

KANSAS VENEREAL DISEASE COMMITTEE

THE Kansas Medical Society will appoint a committee on venereal diseases to act in an advisory capacity to the State Board of Health in the development and execution of programs throughout Kansas.

This action followed a conference between representatives of the State Board of Health and the state medical society.

MICHIGAN BUREAU OF INDUSTRIAL HYGIENE

A BUREAU of Industrial Hygiene has been created in the Michigan Department of Health, with John M. Hepler, C.E.,† of Lansing, Mich., as Director.

A preliminary survey of plant conditions to determine the scope of existing industrial hazards, the location of

† Member A.P.H.A.

potential hazards, and to evaluate the need for preventive measures is being undertaken by the Bureau. One phase of the program will be the collection and analysis of case records of industrial diseases.

PERSONALS

ELDRED K. MUSSON, M.D.,* of Jefferson City, Mo., has resigned as Director of the division of communicable disease control of the Missouri State Department of Health. He will be appointed to a similar position with the Kansas Board of Health.

HARRY E. JORDAN,* of Indianapolis, Ind., assumes his duties as Executive Secretary of the American Water Works Association on Dec. 1. Mr. Jordan has been identified for many years with the Indianapolis Water Company. He is succeeded by Cecil K. Calvert, B.S.,† of Indianapolis.

DR. NORRIS T. OWEN, of Rapid City, S. Dak., was recently named President of the South Dakota State Board of Health. Dr. Carl A. Feige, of Canova, is Vice-President, and Dr. Burt A. Dyar,† of Pierce, is Director of Medical Licensure. Dr. Park B. Jenkins † is Secretary.

EMIL A. STEINER, M.D.,† of Cleveland, Ohio, has been appointed Health Officer of Pulaski County, with offices in Somerset, Ky.

JULIAN O. LONG, M.D.,† of Baltimore, Md., has been provisionally appointed to succeed Dr. James R. Scott * as Health Officer of the Third District of Albuquerque, N. M., resigned.

EDGAR MAYER, M.D.,† and James Burns Amberson, Jr., M.D., have been appointed by the State Industrial Commissioner of New York as Consultants on Dust Diseases.

* Fellow A.P.H.A.
† Member A.P.H.A.

DR. JACK B. PORTERFIELD, Christiansburgh, Va., has been appointed Health Officer of the peninsula district, to succeed Dr. George E. Waters, Williamsburgh, resigned. Dr. Sheldon D. Carey, recently of Abingdon, Va., has been named to succeed Dr. Porterfield as Health Officer of Montgomery County.

DR. WILDER G. PENFIELD, Professor of Neurology and Neurological Surgery, McGill University Faculty of Medicine, Montreal, delivered the first Harvey Lecture of the season on October 15 at the New York Academy of Medicine.

DR. GEORGE K. PRATT, since 1930 Medical Director of the Mental Hygiene Committee of the New York State Charities Aid Association, has been appointed to a similar position with the Connecticut Society for Mental Hygiene. He succeeds Dr. Edgar Van Norman Emery, who has been appointed Professor of Social Psychiatry at Washington University School of Medicine, St. Louis, Mo.

LLOYD B. SHEFFIELD, M.D.,† has been appointed Health Director of the Dallas public school system, succeeding Edythe P. Hershey, M.D.,† of Austin, resigned. Dr. Sheffield has been Assistant Health Director for 5 years.

DR. HAROLD DOUGLAS SINGER, Head of the Department of Psychiatry, University of Illinois College of Medicine, has been put in charge of work to promote undergraduate instruction in psychiatry in the university. The Rockefeller Foundation has granted the university a fund of $15,000 a year for 3 years for this purpose.

DR. JESSE M. DISHMAN, Greensburg, Ky., Health Officer of Green County, has been appointed Health Officer of Caldwell County, to succeed Dr. B. Kirtley Amos, resigned.

LORENZO L. PARKS, M.D.,† Health Officer of Tarboro, N. C., has been appointed Secretary of the Health Conservation Committee which has been organized in Edgecombe County.

J. CLARENCE FUNK, A.B., Sc.D., LL.B.,* formerly of the Pennsylvania State Department of Health, Harrisburg, and more recently with the U. S. Public Health Service, Washington, D. C., has been placed in charge of the educational work of the Virginia State Department of Health.

ALFRED D. GREGG, M.D.,† of Liberty, N. C., has been appointed Health Officer of Vance County, succeeding Zack P. Mitchell, M.D.,† of Henderson, who has been appointed Health Officer of Swain and Graham Counties.

DR. ROBERT M. TAYLOR has been appointed Health Officer of East Haven, Conn., succeeding Paul H. Brown, M.D.†

GARNER M. BYINGTON, M.D.,† of Battle Creek, Mich., for 4 years Medical Director of the W. K. Kellogg Foundation, has resigned to become Director of Medical Relations in the Detroit Department of Health. Dr. Byington will have supervision of the program which attempts to link up the practicing physician with all phases of preventive medicine. He will also supervise the program for medical education.

ABRAM L. VAN HORN, M.D.,† Chief of the Bureau of Child Hygiene of the Ohio State Department of Health since 1934, has been appointed a regional consultant for the Children's Bureau, U. S. Department of Labor. Dr. Van Horn will supervise the maternal and child health program of the Bureau in Maryland, Delaware, District of Columbia, Virginia, North and South Carolina, Georgia, and Florida.

JOHN M. HEPLER, C.E.,† of Lansing, Mich., is the Director of the newly created Bureau of Industrial Hygiene of the Michigan Department of Health.

DR. GORDON E. SAVAGE,† of Osborn, Ohio, has been appointed Health Officer of Greene County. The position has been heretofore half time.

DR. REXFORD A. BURDETTE, of Charleston, W. Va., has been named Director of the Monongalia County Health Department, succeeding Robert C. Farrier, M.D.,† who recently resigned to accept a similar position in Delta County, Mich.

DR. KURT C. BECKER, of Toledo, Ohio, has been appointed District Health Officer, with offices at Royal Oak, Mich., succeeding Charles H. P. G. Benning, M.D., C.P.H.,* who has become Director of Health of Schools of Peoria, Ill.

DR. GEORGE E. COGAN has been elected President of the Hartford Board of Health, succeeding Dr. Robert V. Boyce, resigned.

DR. JAMES W. MILLER, recently Health Officer of Gallatin County, Ky., has been transferred to Green County, to succeed Dr. Jesse M. Dishman, of Greensburg, recently appointed in Caldwell County.

DR. JAMES O. NALL, recently of Murray, Ky., has been appointed Health Officer of Trigg County.

DR. PAUL C. BRATTEN, of New Bremen, Ohio, has been appointed Health Officer of Shelby County, to succeed the late Alfred B. Lippert, of Sidney.

DR. ROBERT J. ROWE, of Kaufman, Tex., has been appointed a member of the State Board of Health of Texas, to succeed Dr. George W. Cox, of Del Rio, resigned.

NOTICE OF

MASSACHUSETTS CIVIL SERVICE EXAMINATIONS
DEPARTMENT OF PUBLIC HEALTH

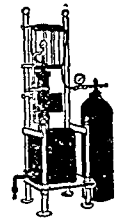
1. Assistant Bacteriologist, Wassermann Laboratory. Minimum Salary $2,160, Maximum $2,760.

2. Public Health Nursing Supervisor. (Examination open to females only.) Minimum Salary $2,040, Maximum $2,400.

3. Public Health Nursing Supervisor. (Examination open to females only.) Premature Infant Program. Minimum Salary $2,040, Maximum $2,400.

4. Social Worker (Medical). Entrance Salary $2,100 and maintenance.

Complete information regarding duties and requirements and application blanks may be obtained from the Division of Civil Service, Rooms 145–152, State House, Boston, Mass. Last date for filing applications Saturday, December 26 at 12:00 noon.



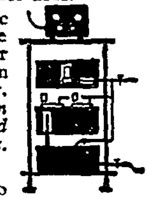
EVERSON Chlorinators

New Low Priced Gas Chlorinators with Metered Control--10 to 30 lb. Capacities

Far better Chlorinators than have ever been offered before near these prices. Metered-control and automatic safety features that permit anyone to operate. Wide capacity range. 3 sizes. Designed for water purification in swimming pools, they are finding many other uses.

New Gas Chlorinators
Metered feed
Intimate Mix
Non-flooding
Self-venting
Wide range
Low price

Everson Electric Chlorinators make Sodium Hypochlorite or Chlorine as needed from ordinary salt and water. *Write for Bulletins on Gas, Chemical and Electric Chlorinators.*



Everson Mfg. Co.
629 W. Lake St., Chicago

DO YOU PREFER

Strain In-Bred Animals?

We breed them—3,000 mice per week. Two strains with different resistance qualities.
Strain CF-1, medium resistant.
Strain CFW, (Swiss) high susceptible.
We also breed rabbits and cavies.
All our animals are under expert care and are continually checked for constancy of maintenance, genetic purity of strain, and bacterial infections. Inbred animals give more constant results. Uniformity is our goal.

CANNED FOODS AND THE PUBLIC HEALTH

III. Chemical Preservatives

• Some of our readers have inquired as to whether or not chemical preservatives are used in commercially canned foods. In certain instances, this question was inspired by the fact that "canning compounds" were formerly sold for use in home canning and preserving operations. Such compounds, however, are rarely used by the housewife of today, and never by commercial canners.

We wish to state here that *no preservatives are used in commercially canned foods.*

Spoilage of food is principally caused by the growth and multiplication in food of microorganisms such as yeasts, molds, or certain types of bacteria. These microorganisms depend upon the food they inhabit for their nutrition and their life processes produce changes in the chemical or physical characteristics of food, or both. These changes lead us to state that the food has "spoiled."

Like other living organisms, these spoilage microorganisms can grow and multiply in a food only as long as conditions remain favorable for their existence. If any environmental factor, such as temperature, moisture or acidity, becomes unfavorable, these spoilage organisms are destroyed, or their development is inhibited.

All methods of food preservation have a common underlying principle; they all alter some factor or factors in the food environment so as to render conditions unfavorable for the growth or development of spoilage organisms in the food.

Thus, foods may be preserved by freezing or refrigeration. which serves to lower the temperature below that optimum for growth of certain spoilage organisms; dried foods keep because the moisture content has been reduced to an unfavorably low level; certain fermented foods keep because of the development of high acidity. All of these methods produce changes in the environment in which the food spoilage organisms must live.

Commercial canning is a method of food preservation in which the temperature factor in the environment is raised to a level above that optimum for growth of spoilage microorganisms. Thus, canned foods keep because in their preparation they are subjected to heat processes in hermetically sealed containers. The thermal processes raise the temperature of the foods to those temperatures at which the most resistant spoilage organisms present cannot grow or survive. (1)

The hermetic seal insures protection against future infection of the food by such organisms.

Thus, commercial canning is a method of food preservation which has for its basis the thermal destruction of spoilage organisms; no chemical preservatives are needed to insure preservation of the foods, and, consequently, none are used.

AMERICAN CAN COMPANY

230 Park Avenue, New York City

(1) The Microbiology of Foods, F. W. Tanner, Twin City Pub. Co., Champaign, Ill., 1932

This is the eleventh in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Committee on Foods of the American Medical Association.
